NOTES AND COMMENTS.

Poor Law Reform.

IN a leading column elsewhere in our present issue we have discussed some of the more important phases of poor-law reform embodied in two recent orders issued from the Local Government Board by Mr. John Burns. It will be well to add a short recapitulation of the chief points. First of all comes the wise direction that no children over three years of age are to be kept in workhouses. This is followed by another equally desirable instruction that all infants under eighteen months are to be medically examined at least once a fortnight, and over eighteen months once a month. Nursing by pauper inmates is abolished once and for all, a step in accordance with modern humane views as to our duty towards the sick poor. Then comes a highly important safeguard in the provision which enables paupers to make their complaints direct to the Guardians. The interests of inmates are likely to be better protected, as it has hitherto been practically impossible for any pauper to lodge an effective protest against official abuses and injustice. At the same time it seems fairly obvious that no system of complaint could be ultimately effective unless provision be made for an appeal to a central authority. There can be little use in appealing to a bad board of guardians!

An Unprofitable System.

THAT skilled nursing should be available for every sick inmate of a poor-law institution is only right and proper. In its absence no authority could claim to be discharging its responsible duties in regard to the treatment of the poor. It is to be hoped that the condition of the nursing service will be materially improved, as in that event there is every prospect that a much better class of probationers would be forthcoming. Mr. Burns also orders the "more careful classification of inmates according to their needs and conditions." To expect this work to be undertaken by the average Board of Guardians is to attach an altogether undue amount of weight and influence to an order issued by the Local Government Board. In our opinion, nothing like proper classification will ever be obtainable except under the compulsion of carefully-detailed legislation. The farce and folly of the casual system is deplorable. Able-bodied men are made to give many hours of labour in exchange for some inadequate and paltry equivalent in food and lodging. They are set to work of a degrading and unproductive nature, and turned out into the street too late in the day to look for work. With wiser management a similar expenditure might be made to produce infinitely better results. It would probably pay the ratepayers to feed a tramp well and turn him out early each day.

Consumption and Tramps.

ONE of the difficulties in dealing with tuberculosis in the "submerged tenth" is that its victims have no permanent dwelling-places. The *bonâ-fide* tramp has a righteous horror of drugs, as well as of soap and water, and he is distinctly an elusive person when a question of medical examination arises. It is said that the Finsbury district of London has become a veritable dumping-ground for vagrants suffering from consumption. The borough has the reputation of being a kind of city of refuge for cases of this description, and, according to the *Daily Citizen*, these poor unfortunates are pouring in every day, herding in the "doss" houses and bringing disease and death to the already overcrowded homes of the poor. Many hospitals and dispensaries are situated within the borough, but the professional tramp who is sick does not come to Finsbury in order to obtain medical relief, but rather that he may lose his identity quickly. If the conditions be as stated, it is certainly time that some official action were taken by the health authorities in the direction of systematic medical inspection of all incoming vagrants, and the compulsory removal of consumptive patients to some institution.

A Layman on Sterilised Milk.

MR. ROBERT MOND, son of the distinguished chemist the late Dr. Mond, has published an attack on sterilised milk in emphatic language. Among his views are the following: "Sterilised milk is a danger to children fed upon it, and definitely predisposes them to tubercular infection. Children who were known to have been fed exclusively from birth upon sterilised milk had developed tuberculosis. Milk was a living fluid intended by nature for immediate consumption. If boiled, it was chemically changed, and lost its nutritive value." His conclusions may or may not be founded upon extensive clinical experience, the only basis on which any sound opinion could be formed. It is fairly obvious that sterilising destroys the bacilli of tuberculosis, but there are many ways other than that of milk in which a baby might become infected. His view that milk loses its nutritive value when boiled needs a lot of proof. Upon clinical grounds most medical men would dismiss that suggestion off-hand as far-fetched and fantastic. However, for some reason or other, Mr. Mond's declaration has attracted some degree of attention, and a good deal of discussion is likely to be raised.

The Proof of the Pudding.

IF he be right in his contentions, then the muncipal milk supplies of sterilised milk must go by the board, for who could possibly advocate the feeding of weakling infants upon milk robbed of its virtues? One well-known Medi-

cal Officer of Health, Dr. G. Quin Lennane, of Battersea borough, has entered the lists against him. Following the modern fashion of medical men, he has communicated his ideas upon the subject, freely and at length, to the *Pall Mall Gazette*. His statistics as to the municipal sterilised milk supply in his district are striking. Out of some 165 infants fed in 1912 only 43 were in good health. The total mortality, however, was only 23, giving a death-rate of 49·3, as compared with 83.0, the general infantile mortality for the borough. While agreeing that sterilised milk is not the ideal condition of milk, he is convinced that it is far less harmful to give infants sterilised milk than risk the unsatisfactory conditions under which the milk supply of the country is at present produced. If sterilised milk be unharmful for the defective class of children relieved at the Battersea depôt, it must be doubly less harmful to healthier babies. It looks as if Mr. Mond were in for a somewhat strenuous discussion with the medical profession.

LEADING ARTICLES.

THE POOR LAW MEDICAL SERVICE.

As President of the Local Government Board, Mr. John Burns has recently issued two new orders of first-rate importance. One is of a general character, while the other deals with the matter of nursing. The need of drastic reform in the desolate region of poor law administration has long been apparent. It was hoped that when Mr. John Burns appeared upon the scene the Augean stables would be cleared out forthwith by a man who united experience with sympathy and strength. He has now held the reins in his hands for a span of years sufficient to have recast the poor law system from one end to another. Within that period some of his colleagues have placed on the Statute Book social measures whose magnitude might well have daunted the strongest of politicians. Even Mr. McKenna, who professes himself unable to exclude herbalists from performing medical services under the Insurance Act, has fathered the Mental Deficiency Act and mitigated various rigours of the criminal law. It is Mr. Burns, the erstwhile strong man of the Cabinet, whose performance on the parliamentary stage has proved to be stale, flat and colourless. One characteristic of his administration is a partiality for departmental orders. Although a great deal of good can doubtless be achieved by orders based on existing powers, it is nevertheless fairly obvious that the reform of the poor law demands the enforcement of certain principles by means of fresh legislation. Under the general order just issued, Mr. Burns gives Boards of Guardians power to make regulations for the control of workhouses. Past experiences render an increase of authority in such a direction a somewhat hazardous experiment. Such a change will not render good workhouses better, but it may well make bad workhouses worse. At any rate, Boards of Guardians have reduced the whole system to a state that is nothing short of a national scandal and reproach. Then, to make matters worse, Mr. Burns has placed the actual control of the workhouse in the hands of a House Committee, which means virtually that the management will in future be practically withdrawn from that share of public criticism which is absolutely essential to the efficiency of all poor law administration. It may be that Mr. Burns has in view other orders that will level up and consolidate the piecemeal fabric which presumably reflects his view of a broad and statesmanlike policy. It would be more to the point were he to introduce legislation to provide compulsory classification of paupers, to abolish disentranchisement of those relieved, to recast out-door and casual relief on humane and commonsense lines, to inquire into and regulate the whole system of contracts, to render inspectorship and central control a living thing instead of a sham, to define the conditions of guardianship, to pay for medical service at an adequate rate, in short, to tackle the whole question of poor law reform as a great politician, instead of tinkering with it in the time-serving spirit of a subordinate government official. As regards the other recent order of Mr. Burns, to which reference has been made, there is every reason to believe that a great deal of good will result from the attempt to improve nursing in poor law institutions. In not a few workhouses and workhouse infirmaries, efficient nursing is conspicuous by its absence, as we find testified from time to time in various public scandals. The best point in Mr. Burns' new order is the abolition of nursing by pauper inmates. It seems almost incredible that society should have tolerated so inhuman a practice until the year 1914. If Mr. Burns wishes to make his nursing arrangements efficient in large hospitals he will do well to limit the activities of the nursing matrons strictly to their own department. He will do well, also, to provide carefully against excessive hours and other unfair conditions imposed upon nurses. In conclusion, it may be well to remind him of the fact that poor law medical officers are, as a rule, miserably underpaid. Their salaries, originally fixed upon an utterly inadequate estimate, require liberal revision in order to bring them up to the scale commensurate with the living wage of members of a liberal profession discharging responsible public duties. Until medical service is placed upon terms of adequate pay for a reasonable amount of work, the health of the nation must be undermined to a corresponding degree. The order that regulates nursing is sane and sensible, and goes to the root of the matter. In order to be of full and permanent value, however, it requires supplementing in the direction of an improved poor law medical service. Meanwhile, the total cost of Local Government Board expenditure is stupendous, and demands the attention of some statesman who can combine financial resource with the clear insight of a great social reformer.

CURRENT TOPICS.

The New Year Honours.

IN the list of New Year Honours are the names of some thirteen members of the medical profession. To Sir Christopher Nixon, Bart., a past-President of the Royal College of Physicians in Ireland, and one of the most distinguished members of the profession in that country, who is to be sworn a member of the Privy Council in Ireland, we beg to offer our heartiest congratulations. The only new medical baronet is Sir Thos. Joseph Stafford, Medical Commissioner of the Local Government Board in Ireland, and a worthy recipient of that distinction. The honour of Knighthood is bestowed upon Surgeon-General A. T. Sloggett, C.B., C.M.G., Director-General of the Army Medical Service; Dr. H. B. Allen, Professor of Pathology and Dean of the Faculty of Medicine in the University of Melbourne; and Dr. T. B. Nariman, of Bombay. Sir Rickman Godlee and Sir William Job Collins become K.C.V.O., whilst the C.B. is conferred upon Surgeon-General H. G. Hathaway, Deputy-Director of Army Medical Services in India. The C.I.E. is conferred upon Major J. C. Robertson, I.M.S., Sanitary Commissioner with the Government of India. The Kaisar-i-Hind Gold Medal for public service in India is bestowed upon Dr. W. Stokes, Chief of the Basel Medical Mission; Dr. M. B. Carleton, in charge of the Leper Hospital at Subathu, Punjab; and the Rev. J. Shepherd, M.D., D.D., of the Medical Mission at Udaipur, Rajputana. Surgeon-General A. W. May, C.B., Director-General of the Medical Department of the Royal Navy, has been created Honorary Physician to the King. To all the above our readers will join with us in offering the best congratulations of the medical profession upon their well-merited distinctions.

Rectal Anæsthesia.

ON November 20th, Dr. J. T. Gwathmey announced his new method of anæsthesia before the New York Society of Anesthetists. It consists in the rectal injection of olive oil and ether, and some of the American medical papers are making quite a fuss about it. They say it is "danger-free"; that it meets all Crile's anoci-association requirements, and they bid us remember the date given above as one which "will become a memorable one in the minds of anesthesia." This somewhat puzzling remark is followed by a mark of admiration, which, we fear, is meant as a sign of triumph at this masterly distortion of the English tongue. But the method is of more importance than the language used about it. For children it is recommended to inject into the rectum for every twenty pounds of body weight one ounce of a 55 per cent. solution of ether in olive oil, and for adults, irrespective of age, size or anything else, eight ounces of a 75 per cent. solution one hour after a "hypodermatic" of morphine. The suggestion to give either *per rectum* is an old one. It has been twice tried and twice found wanting. The only new thing this time is the admixture with oil. This certainly removes the danger of rectal necrosis and the consequent peritonitis. It still leaves us with a patient who may have a poisonous dose of irremovable ether. The enthusiasts of the idea claim that, towards the close of the operation, an enema of cold water will remove the residue of the anæsthetic mixture. Now it has been shown by the X-ray that rectal injections containing bismuth often pass to a considerable extent above the ileo-cæcal valve, under which circumstances absorption would take place as long as any ether was present in the intestine. We are bound to consider a eulogy of such an uncontrollable ether-administration out of place. The dose is too irrevocable. The line between deep anæsthesia and death is too fine for us to sanction a method which might compel us to watch a patient slipping from one into the other without being able to put out a hand to save him from the effects of our hour-gone industry. We prefer inhalation. All we must do then is to know when to stop, and to stop accordingly.

Midwives and Character.

EVERYONE will agree that midwives and nurses—as well as medical men—should be persons of high moral character. In its endeavour to maintain this status of character the Central Midwives Board will have the whole-hearted support of the medical profession and the public. Nevertheless, we cannot but think that in a recent case which came before the Board, the midwife, who was already on the Register, was treated with unnecessary severity. A young woman of respectable parentage was seduced under promise of marriage, and gave birth to a child. Deserted by her friends, in order to support herself and her child in an honourable way, the girl trained as a midwife. She brought testimonials of character and obtained admission to the Register. Her past history having afterwards come to the knowledge of the Central Midwives Board, her name was removed from the Register. It is to be noted that there was no charge of misconduct in any professional capacity, nor at any time while she was on the Register. In the interests of morality we hold that it is of the utmost importance that avenues of honest work should be kept open to women who have, as the saying is, "got into trouble." We do not believe that one mistake such as this girl made is evidence of inveterate depravity of character. The closure of opportunities of honest work drive such a one almost necessarily to the only means of livelihood left. We hope that it may be possible for the Central Midwives Board to reconsider its decision in this case.

The Weir Mitchell Treatment.

IT is not given to many medical practitioners to have their name permanently associated with some therapeutic method or to enable the whole of their discoveries to be described in one word—their own surname. We do not refer to the use of proper names as titles of diseases, or as descriptive of some clinical test, for a dozen such will readily occur to the mind. There has only been one Lister, and one Listerian method, upon which the whole fabric of modern surgery is based. The name of Dr. Silas Weir Mitchell, whose death took place the other day at Philadelphia, serves as another illustration, though upon rather a smaller scale, of personal nomenclature in medicine. In 1881 this distinguished physician published his work on "Diseases of the Nervous System, especially of Women," and his observations in the field of neurology led to a change in our conception of the hysterical state. His celebrated "rest-cure" system has now acquired international fame, and few practitioners would now think of treating an advanced case of neurasthenia without having recourse, even in a modified degree, to "Weir Mitchell treatment." Essentially its principles consist of removal from all home-surroundings and ties, complete rest, systematic massage in place of muscular exercise, and regular overfeeding for six or eight weeks, followed by change of air in some bracing locality. The use of drugs in conjunction

with the treatment is left entirely to the discretion of the physician. Nowadays it is, perhaps, becoming more usual to employ psycho-therapy as an adjunct to Weir Mitchell treatment, though this accessory was not taken into consideration by the eminent physician whose loss is now deplored.

Spontaneous Rupture of the Malarial Spleen.

MOST authorities upon tropical medicine are agreed that rupture of the spleen may occur in malaria as a result of some severe or even of a trivial injury. Spontaneous rupture of the spleen in connection with malarial attacks has been described, but it is a very rare phenomenon. Drs. Lloyd Noland and F. C. Watson (*a*), of the Colon Hospital, have found only three cases from among the clinical and *post-mortem* records of about 30,000 cases of malaria admitted during the past eight years. In each of these the most careful inquiry failed to elicit any history of traumatism. Two of the patients were black, natives of Barbadoes and Jamaica, and the third a Spaniard, white. All three were treated by operation, with one death, the clots being removed and the hæmorrhage controlled by gauze tampons. The ruptures were observed in each instance to have taken place on the diaphragmatic surface of the organ. The symptoms were those of severe abdominal pain, general tenderness and rigidity of the abdominal muscles, and dulness in the left flank progressively enlarging (Ballance's sign). The spleen need not necessarily be greatly enlarged in order to undergo spontaneous rupture. In examining the patient deep palpation or forcible percussion should always be avoided, and even exploratory puncture of the organ for diagnostic reasons is not without risks. When the condition is suspected, the best treatment is early surgical intervention.

Angels Rush In.

ACCORDING to the *Australasian Medical Gazette*, Lady Tennessee Cook advocates a drastic measure to prevent the imperfect man from entering into holy matrimony. She holds that physicians should break all bonds of honour and etiquette, and on discovering an imperfect male should say to all the world—this is not a man (within the meaning of the Act). The lady is also alleged to recommend that the man be branded with a hot iron, so that he may be recognised and shunned. Of course, these statements are absurd, but the underlying idea has often been presented to us in more reasonable, and therefore more convincing, language. This idea is that the unfit man should not be allowed to propagate. It seems quite a simple idea when said quickly and not thought about. Really it opens up untold vistas of unending controversy. We must determine who is unfit, and who is liable to transmit his unfitness, and what kinds of unfitness, when transmitted, are such as to justify our stopping their transmission, what steps we can take to stop the marriage of men who might transmit disease, whether the disease might not be more widely spread by such stopping of marriage, and a host of other pertinent queries at once suggest themselves. And atop of all this comes the question as to how much of this regulation a modern people will stand. Off-hand hyperbole is easy and ignores difficulties. It does not brush them aside. Practice only shows the imperfections of exaggerated theory and a sensible idea run wild is a laughing stock for the people. Well-meaning women with a hypertrophic enthusiasm and no statute of limitations do more harm than good. Their cause may be just, but the best cause cannot withstand the continued advocacy of unrestrained eulogy.

(*a*) *Proceedings of the Canal Zone Medical Association* vol. v., part 1.

Pneumonia in Rand Mines.

THE first section of the second part of the report prepared by Sir Almroth Wright to the Rand Labour Association on "The Results of an Inquiry into the Causation, Phrophylaxis, and Treatment of Pneumonia among Native Labourers" was published last week. It will be recollected that about a year ago the first part of the report was issued, dealing with the drug treatment of pneumonia, especially by Professor Morgenroth's preparation, ethylhydrocupreinhydrochlorate, this compound being shown to be unsatisfactory. It is true that the drug exerts a powerful influence upon pneumococci *in vitro* and cured mice with the disease, but human beings did not react in so successful a manner. As might be expected from the apostle of vaccine-therapy, the report is taken up with the question of this mode of treatment as applied to the prevention and cure of pneumonia. Sir Almroth describes in detail the experiments in which he showed that the pneumococcus was the cause of the disease on the Rand, and he then discusses the mode of preparation of his vaccines. It is necessary to bear in mind that a minimal dose of vaccine does not enter the blood-stream, but is "anchored" locally, and only acts by increasing the general powers of resistance. A much larger dose, on the other hand, actually circulates in the blood, producing different results in different individuals. The whole art of the administration of a vaccine, whether in pneumonia or in any other specific infection, lies in adjusting the doses to the reaction produced, controlled, if necessary, by a careful and repeated examination of the opsonic index. The concluding section of the report, giving the general results and recommendations, will be published a little later.

An Irish Medical Student of Eighty Years Ago.

ANY human document which throws light on the life of medical students in the past is bound to be of interest. In particular this is the case if it tends to correct mistaken current opinions. We are too ready to assume—on the evidence of the caricatures of Dickens and others—that the typical medical student of the first half of the last century was more or less of a vulgar rake. Those who remember the medical men who were students of that time must often have wondered how the idle and dissolute student developed into the dignified and self-reliant practitioner. In the November number of the *Dublin Journal of Medical Science*, Dr. T. P. C. Kirkpatrick publishes a diary kept by a medical student in Dublin from 1831 to 1837. The entries are brief, but many of them of considerable interest. Robert Thompson, whose long life only ceased a few years ago, even as a student took a serious interest in his work. We find notes in his diary concerning interesting cases he saw and operations he witnessed. For instance, on March 22nd, 1836, he saw James William Cusack tie the carotid for aneurysm. He notes on Christmas Day, 1835, that a puerperal patient from whom a retained placenta had been removed three days earlier, "is very well, but the pulse is 130; no pain in the hypogastrium, but a very slight tenderness; no fever." Thompson had healthy interests outside his work. He and the other "boys at Steevens'" possessed a boat, in which they had

many adventures in the Bay. He had a taste for shooting which he was able to satisfy when on his holidays. A few entries refer to junketing. On June 6th, 1835, he "drank punch, played backgammon"; the next day's entry begins: "Very sick, headache." Of the winter of 1833-34 he writes: "Colles [*i.e.*, William Colles, afterwards surgeon to Steevens'] and I spent a jolly winter, drank a deal of punch, went to the theatre at least two a week, passed the second examination May, '34." One or two tussles with watchmen are recorded. On the whole, we carry away the impression that the medical student's life in Dublin eighty years ago was a pleasant one—a healthy blend of work and play. Thompson and his friends were pleasant young fellows, and differed but little from their successors of to-day.

The Investigation of Anthrax.

THE eighth annual report of the Anthrax Investigation Board for Bradford and district, for the year ending October 31st, 1913, has just been issued. During the year 933 samples have been tested for the presence of anthrax spores. Of these 865 were blood-stained. The spores were discovered in 111 samples, five of which were not blood-stained, and which were mostly taken in connection with cases of anthrax that had occurred in various districts. Experiments were conducted in the spring of 1913 in regard to the use of steam as a disinfectant, as a result of which the committee agree that disinfection by steam cannot be applied to ordinary wool or hair except under conditions that would stop any trade in the sorts so treated. The method can, however, be applied to blood-stained material that has been sorted out or otherwise separated from the bulk. Even this restricted possibility may be regarded as a step forward, for blood-stained material need no longer be regarded as absolute loss, but as a waste product. The Board earnestly urge that advantage should be taken of this knowledge, and that all blood-stained material should be thrown out before any process of combing takes place. Reports of 23 cases of anthrax were received during the year, of which three proved not to be anthrax. Three cases were fatal—two external and one internal. Sclavo's serum was employed in nearly all, with good results. Salvarsan was used in two cases, in both as a last expedient. Although much remains to be done to ensure quick recognition of the disease and the prompt application of remedies, it is gratifying to note that there is a decided improvement in these respects. Much of this must be attributed to the zeal of Dr. F. W. Eurich, Bacteriologist to the Board, and his assistant, Mr. W. Willey.

PERSONAL.

DR. J. TUDOR GRIFFITHS has been appointed Medical Officer of Health for Prestatyn.

PROFESSOR G. H. F. NUTTALL, F.R.S., has been elected a foreign member (*honoris causa*) of the Royal Hungarian Society of Medicine.

DR. J. SHERWOOD NEW, M.B., B.S.Lond., D.P.H. Camb., has been appointed Medical Officer of Health for the Amersham Rural District.

DR. ALEXANDER GOODALL, F.R.C.P.Edin., has been appointed by the managers of the Royal Infirmary, Edinburgh, to be one of the Assistant Physicians to the Institution.

THE Town Council of Glastonbury have placed on record their appreciation of the services of Dr. David Lawrie, Medical Officer of Health, who has relinquished this appointment upon the ground of ill-health.

DR. C. R. BOX will deliver an address on "Pellagra," illustrated by lantern slides, at the meeting of the North-East London Clinical Society, to be held on January 8th, at 4.15 p.m., at the Prince of Wales's General Hospital, Tottenham, N.

WHEN Dr. Winstanley, of Haslemere, was reappointed Medical Officer of the adjoining districts of Hindhead and Shottermill by the Farnham Board of Guardians on Thursday it was stated that there was no medical man in the two districts named willing to accept the appointment.

DR. L. RAJCHMAN, M.D. (Cracow), will deliver the first of a series of eight or nine University Lectures on "Anaphylaxis" at King's College Department of Bacteriology (University of London), 62 Chandos Street, W.C., on Thursday, January 15th, 1914. Admission is free, without ticket.

THE names of two medical men appear in the list of High Sheriffs of Counties appointed by the Lord Lieutenant of Ireland:—Dr. Francis Creighton FitzGerald, of Newtownbutler, as High Sheriff of Co. Fermanagh, and Lieut.-Colonel C. R. Kilkelly, C.M.G., M.V.O., of Drimcong, as High Sheriff of Co. Galway.

DR. J. PEARSE, Medical Officer of Health for Trowbridge, was the recipient the other day of a suitable presentation by his professional colleagues in Wiltshire and East Somerset as a token of their esteem and in grateful recognition of much arduous and valuable work cheerfully undertaken by him on behalf of the medical profession.

THE French Government have conferred the honour of the grade and diploma of "Officier de l'Instruction Publique" in the Academy of France upon Sir Thomas Oliver, M.D., Sir Ronald Ross, M.D., Professor E. W. Hope, M.D., and Professor Georges Dreyer, M.D., as presidents of the sections at the congress of the Royal Institute of Public Health held in Paris in May last.

SIR JOHN BATTY TUKE, M.D., F.R.C.P., LL.D., F.R.S., D.Sc., a former President of the Royal College of Physicians, Edinburgh, an authority on mental diseases, left, in addition to real estate, personal estate in the United Kingdom valued at £30,750. The testator left to the Royal College of Physicians, Edinburgh, his bust by John Hutchison, R.S.A., on condition that it be placed in the Great Hall of the college, and he also left to the college his etching of Darwin by Rajor.

THE names of two Irish medical men appear in the list of New Year Honours, given in full in another column. Sir Christopher Nixon, who is to be sworn a member of the Irish Privy Council, is a former President of the Royal College of Physicians of Ireland, and Vice-Chancellor of the National University. He is Professor of Medicine in University College, Dublin, and Senior Physician to the Mater Misericordiæ Hospital. He was knighted in 1895, and received a baronetcy in 1906. He is one of the Physicians to His Excellency the Lord Lieutenant of Ireland. Mr. T. J. Stafford, C.B., F.R.C.S., who receives a baronetcy, is the medical member of the Local Government Board for Ireland. He was formerly dispensary doctor at Boyle, and later a medical inspector of the Local Government Board.

CLINICAL LECTURE

ON

TUBERCULOSIS AS A CAUSE OF MENSTRUAL DISTURBANCES.

By Dr. JOSEPH HOLLOS,

Budapest.

[Specially reported for this Journal By Dr. ADOLF ERDOS, Nagyvarad, Hungary.]

SPECIAL examinations and researches conducted on women suffering from latent tuberculosis during the past five years had led me to conclude that the majority of cases of menstrual disturbances are caused by consumption, and that they can be relieved or even completely cured by special ætiologic treatment. The discovery of the ætiology of menstrual disturbances is not only very important from a therapeutic point of view, but also because it is a very early appearing sign of tuberculosis, which fact is most important in the diagnosis of cases.

These disturbances have proved themselves to be toxic symptoms of tuberculous infection somewhere in the organism, and, as such, are signs of general intoxication.

Among the latter symptoms subjective appearances and functional disturbances of the most diverse type may be found, *e.g.*, palpitation, acceleration of the pulse, vasomotor disturbances, affections of the stomach and intestines, sweating, headaches, giddiness, insomnia, nervousness and different pains, chiefly smarting of the joints and muscles, etc. Mostly one or other of these symptoms presents itself with menstrual disturbances; sometimes, however, there are cases in which several of those symptoms are present.

Menstruation generally begins at the age of 13–15 years in our climate, but sometimes even as early as 11–12 years. The cases where menstruation begins early as well as those where it begins late, *i.e.*, after 16 years, are suspicious in themselves, and lead to the conclusion that latent consumption is present. I have observed numerous cases where girls between the ages of 16 and 20 began to menstruate during special treatment against tuberculosis or after completion of the same.

Menstrual disturbances appear at the same time as other toxic symptoms of consumption, and are often even the premonitory symptoms of same. The irregularities may take very different forms. Very often hæmorrhage, which was regular up to then, takes place earlier or oftener, *e.g.*, twice monthly or, in other cases, menstruation sets in some days or may be longer or shorter and the loss of blood remarkably great or very small. A very frequent toxic symptom is amenorrhœa lasting months or years.

Among menstrual disturbances the painful hæmorrhage, *i.e.*, dysmenorrhœa, is worthy of the greatest attention. This is accompanied in most cases by diverse general symptoms. The pains and their accompanying symptoms sometimes last for days and completely exhaust the patient. Dysmenorrhœa, as well as other menstrual disturbances, may occur at the time of the first menstruation, or they may occur later, and eventually together with toxic or other symptoms. In the case of this so-called secondary dysmenorrhœa infection probably did not take place in childhood, but only after the age of puberty.

In collaboration with Eisenstein, gynæcologist in Szeged, I published the results of my work in this field in the *Gynækologische Rundschau* (1907) and in the *Zentralblatt fur Gynækologie* (1908). Gräfenberg (*a*), gynæcologist in Kiel, has corroborated our results, and has shown the connection between dysmenorrhœa and tuberculosis. He also recommends treatment for consumption in cases of primary dysmenorrhœa, but, on the other hand, he does not consider consumption to be the cause of secondary dysmenorrhœa. Quite a series of my cases are in opposition to this assertion, in that they prove that there is no difference at all between primary and secondary dysmenorrhœa from an ætiological point of view.

During my investigations of the ætiological cause of disorders of menstruation I have made records in 712 cases. Unfortunately in 351 of these cases I only noted the first menstruation. Among the latter 46 patients menstruated early, *i.e.*, before the age of 13, and 15 of these even as early as 10 and 11 years. 66 patients menstruated late *i.e.*, after the 15th year, and of these 12 between the ages of 18 and 21. Of the 351 cases abovementioned menstruation began early or late in 32 per cent.

Pronounced dysmenorrhœa, or painful hæmorrhage, accompanied by most diverse general symptoms, was observed in 270 cases. Out of these menstruation was painful from the very beginning in 138 cases, while in the other 132 cases, the pains presented themselves only after one or more years. I found amenorrhœa in 64 cases. This lasted from two months to two and a half years, and in a case ending in recovery it lasted even four years. Many of these cases of amenorrhœa were noteworthy, 26 of the 64 cases had unfavourable prognoses. Among the general symptoms accompanying menstruation all toxic symptoms were to be found on a smaller or larger scale. There were: headache, giddiness, loss of appetite, and also nausea. Further, the following symptoms were often also present: vomiting, stomach-ache, heartburn, palpitation of the heart, fatigue, irritability, restlessness, constipation, and as rarer symptoms I may also mention difficulty in breathing, diarrhœa and sweating.

One hundred and eighty-eight women whom I treated for at least two months suffered from pronounced menstrual irregularities, viz., dysmenorrhœa, abnormal hæmorrhage (either much or little) and amenorrhœa. 126 of these cases were cured, *i.e.*, were freed from menstrual disturbances, 37 were ameliorated, and the condition of 24 was unchanged at the end of treatment.

In the case of a great number of these 126 certified cured patients menstrual irregu-

(*a*) E. Gräfenberg, "Dysmenorrhoe und Tuberkulose," *Münchener med. Wochenschrift*, 1910, No. 10.

larities had not re-appeared for two or even three years; if, however, such toxic symptoms re-appeared, as they really did in many patients, they were cured by a new special treatment. In many cases I have found that the first or, more rarely, the first few hæmorrhages have been attended by greater pains than ordinarily, and even in some cases where hæmorrage was painless before, pains have been felt. These symptoms must be considered as local reactions of the special treatment or as toxic symptoms caused artificially. I have also succeeded in artificially producing dysmenorrhœa for experimental purposes bymeans of izotoxin by working on a dualistic basis after the Spengler tuberculin treatment.

Twelve patients menstruated for the first time during special treatment. Five of these were between 16 and 20 years of age. It must be said that menstruation was regular and painless in all these cases. Hæmorrhage was irregular in one case only, and this became regular on further treatment.

Of the 712 patients examined hæmorrhage was regular and painless in 213, *i.e.*, in 30 per cent. of all cases.

It is remarkable that a most unfavourable prognosis could be established for many of these cases, and a number of the patients are already dead. For this reason I have specially put these cases together. Among 712 cases I found 119 for which the most unfavourable prognosis could be established. *Of these 119 patients 75 had regular and painless menses.* The difference is still more remarkable when we separate the 119 cases from the others. We then see that menstruation was regular and painless in 138 cases of the 593, for which a more favourable prognosis could be established, *i.e.*, in 23.3 per cent., whereas menstruation was regular and painless in 75 cases of the 119, for which an unfavourable prognosis could be established, *i.e.*, in 63 per cent.

By this opportunity I want to give an explanation of this remarkable fact, and at the same time to throw light on the value of the prognoses for menstrual irregularities and toxic symptoms.

Those researches which I have conducted on more than 1,000 persons suffering from latent consumption, with a view to seeing how the clinical symptoms of these cases manifest themselves under treatment with tuberculin or "Immunkörper" (Spengler) have led me to believe that the toxic symptoms observed in cases of tuberculosis depend on the degree of lytic immunity of the system. Somewhere in the system, most often in the lungs or peribronchial glands, a latent consumption node, or nodes, appear which slowly, but permanently, render the system immune by their toxic products. This immunity is not, however, complete. In the different organs, and also in the blood itself, toxins are circulating which irritate the nervous system and the different organs. By the increase of lytic immunity the sensitiveness against poisons also increases towards toxins by which the system begins to react on them. *The different toxic symptoms and also menstrual disorders are nothing else but the spontaneous reaction of the system sensible against poisons or chronic poisoning.* This condition can last years and even decades without any evidence of tuberculosis, simply by reason of the immunity present. If the original node has been completely cured in the meantime then the symptoms of poisoning also completely disappear, especially if they have not lasted too long. In the latter case chronic changes, which are capable of making the symptoms of illness lasting, develop in the different organs, as has been demonstrated by Poncet and his school. Poncet and Leriche (*a*) have concluded partly on ground of clinical and partly on ground of pathological observations, that tuberculosis plays the greatest *rôle* in the ætiology of menstrual disorders. They have established the local changes of the sexual organs in all these cases, and Poncet groups them under the name of "tuberculose inflammatoire." Under this name are to be understood chronic inflammatory changes which also originate from tuberculosis, but which are without the special macroscopic and microscopic changes. In these cases chronic endometritis, serious inflammation of the epiploon of the uterus, and often of the oviducts, pustulary degeneration of the ovary, chronic inflammation of the perimetrix, and thickening of the epiploon were to be found.

In my cases a gynæcologic examination was made in few cases only, but the results obtained have confirmed and strengthened those of Poncet. In most of these cases secondary affections of the endometrium and perimetrium were found, and even in the cases of three virgins these chronic inflammatory changes were observed. These examinations were made in cases of grave dysmenorrhœa or amenorrhœa, every one of which was either temporarily or permanently cured by the special treatment. The often recurring leucorrhœa in cases of latent tuberculosis is the result of chronic endometritis. This is caused by the toxin of bacilli and often affects little girls.

The uncombined toxins cause not only toxic symptoms, but also macroscopic and microscopic morbid changes by reason of their constant irritation. The peculiar *role* of these toxins chiefly asserts itself in cases of lytic immunity and simply in cases for which a favourable prognosis had been established.

The more pronounced this immunity is the more is infection accompanied by the most diverse toxic symptoms which are the result of the developed poison receptivity and thus also by menstrual disturbances. In very many cases an invalid has been affected by a whole group of symptoms without our having been able to establish the tuberculous origin of these symptoms only through the excellent and often permanent results obtained by using the tuberculin or "Immunkörper" treatment.

The more the toxic symptoms are wanting in the anamnesis, the more suddenly illness begins with signs of consumption and the less these signs are accompanied by manifestations of reaction, so much the more reason have we right to assume the abscence of immunity of the system and to count on the quicker extension of the course of the tuberculosis. I have established the connection between prognosis and intoxication symptoms by means of figures. Among 712 cases I found 119 for which an unfavourable prognosis could be established or whose condition continually went from bad to worse. Of these 119 cases menses were regular and painless in 63 per cent., while of 593 cases, for which a favourable prognosis had been established 23.3 per cent. had regular and

(*a*) A Poncet et R. Leriche, "La tuberculose inflammatoire," Paris, O. Doin, 1912.

painless menses. On the other hand dysmenorrhœa occurred in only 12 per cent. of the former cases and in 40.4 per cent. of the latter.

In the same measure, as immunity decreases owing to bad hygienic conditions, improper nourishment, repeated infections, etc., intoxicational symptoms, and consequently menstrual irregularities begin to appear.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Wyatt Wingrave, M.D. Lond., Pathologist, London Polyclinic, &c. Subject: "Diagnostic Errors in Clinical Pathology."*

ORIGINAL PAPERS.

THERMO-THERAPEUTICS.

BY PROFESSOR M. A. ZIMMERN, M.D.
[SPECIALLY REPORTED FOR THIS JOURNAL.]

PART. I.

DIATHERMY is a form of thermo-therapy which utilises electric energy for the production of thermal effects in the depths of the tissues. It constitutes a thermo-therapeutic procedure wholly different from those by which heat was formerly utilised in clinical practice. The older methods of application, whether local, as in the use of the cataplasm, warm bath, or hot-air douche; or general, as in application of the vapour bath or electric light bath, are all characterised by exogenous provision of heat. The subcutaneous tissues are heated by thermal conduction, and only after the skin itself has been warmed. Besides, as the circulation becomes very active on account of the dilatation of the capillaries, the heat is kept continuously carried off by the blood-current; and thus all the circumstances combine to hinder deep penetration of the therapeutic agent.

In diathermy, on the contrary, the source of the contributory heat is endogenous—that is to say, the increased quantity of heat is produced locally in the depths of the tissues; where the actual amount depends on the degree of their ohmic resistance and the square of the intensity of the current. The physical principle which forms the basis of this method is the "Joule effect" (*a*) of electric currents—that is to say, the degradation of electrical energy into heat when expended on a resisting medium. Whether the resisting material be a metallic body, or an electrolyte, as in the case of the organic tissues, this transformation inevitably takes place. In the second case, however, the importance of the Joule effect varies with the nature of the current. When the current is continuous, the electrical energy is partially transformed into chemical energy—in the form of electrolysis and calorific energy—of which the amount is relatively small. If, on the other hand, the electrolyte be traversed by an alternating current, the heat production is practically the sole manifestation of the passage of the same. In order to produce a considerable quantity of heat in the tissues by application of the continuous electric current, we should require to utilise an intensity which would produce chemical burns (electrolysis); and, on the other hand, by application of the ordinary alternating current insupportable tetanic muscular spasm would be produced. Thus the problem of supplying a notable contribution to tissue heat production by the Joule effect could only be solved by the employment of high-frequency currents; which, as in case of the use of alternating currents, have no electrolytic action; and, as high-frequency currents, are ineffective in regard to stimulation of motor and sensory nerves.

(*a*) The Joule effect is well-known; it is by its influence that rheostats are heated, and that lamps show light. Joule's law—which gives, for unit of time, the ratio between quantity of heat disengaged, resistance, and intensity of current—is thus expressed for the alternating current: Q being the quantity of heat in gramme-calories $= \frac{RI^2 \text{ eff.}}{4.16}$.

We know that muscle does not react to stimulation with an alternating current with sinusoidal waves. When the frequency reaches 20 or 30 alternations per second, the muscle passes into tetanus; and tetanus is produced by all frequencies comprised between those numbers and 5,000 alternations per second, or so. But, beyond the number 5,000, the muscle becomes less and less responsive; and it does not react at all to the billions of stimuli per second which are produced by the so-called high-frequency oscillations. There is then an apparently infinite degree of probability that our motor nerves—and in like manner the sensory—are specially organised so as to respond to those vibrations only which are within a definite range of frequency. This suggestion is all the more probably true, as it harmonises with the laws of irritability as displayed by the nerves of special sense. The optic nerve is, in fact, irresponsive to the stimuli of ether waves of a rate of repetition below 394 trillions (that of the lower extremity of the visible spectrum) and above 758 trillions (limit of spectral violet) per second. Now if it is certain that, as in all the alternating currents, the high-frequency currents heat the electrolytes through which they pass, we may well ask whether Joule's law is integrally applicable to the organism when placed in the circuit of the high-frequency current. As Bergonié and Réchou have asked: "The law is true for metallic conductors, but is it likewise true for organised tissues? It is only by a daring generalisation, and one which is not justified by experimental facts, that we can pass from one to the other."

An experiment made by Bergonié (which will be again referred to) shows "that it is probably somewhat daring to speak of the application of Joule's law" (the temperature of the mid-section of a block of muscle traversed by a current having been different from that of the extremities). "Besides, in allowing to that block a mean specific heat of 0.8, this gives us a resistance of nearly 100 ohms—that is to say, one sharply disproportionate to what we have been accustomed to call the resistance of a tissue." Besides, as Wertheim-Salmonson has shown, the law of Joule is applicable only to a conductor without "self" or capacity; which is exactly opposite to the fact in the case of the living organism, of which the capacity is notable. Accordingly, in determining the quantity of heat absorbed by the human body, in function of intensity, Wertheim-Salmonson, instead of having recourse to a delicate process of calculation, prefers an experimental determination of the same "by substitution." The arrangement in circuit with a source of high frequency of two incandescent lamps of 16-candle power, and resistance of 240 ohms, gives, when the thermal milliampère meter registers 510 milliampères, an energy of $W = RI^2$ eff., or $2 \times 240 \times 510^2 = 125$ watts per second; which represents approximately 1.7 calories per minute, or 35 calories in 20 minutes (which corresponds to a *régime* of 2,500 calories per twenty-four hours, or nearly that of the normal thermogenesis).

HIGH-FREQUENCY CURRENTS.

This is another instance of the work of the German school causing the recognition in France of a method which first saw the light there, and which the electro-therapeutists had actually been utilising to some little extent for years—without knowing it, as M. Jourdain did with prose. In 1892, d'Arsonval, who had just previously constructed an apparatus for the production of high-frequency currents, had already shown "that we are able to recognise a variety of heat which is directly accompanied by an abundant production of sweat." In 1893 he was able to pass through the arms of a number of individuals a high-frequency current of 3 ampères without producing any other phenomenon than an intense sensation of heat at the level of the wrists. This sensation was the only one that limited the intensity of the current which could be borne by the individual experimented on. In 1896 he demonstrated the fact that we can pass high-frequency currents through the bodies of animals of such intensity as to raise them to a very high temperature by the Joule effect, and without any effect on either sensibility or muscular contractility. In some animals, the calorific effect produced by the passage of the current was such

that the hind legs were literally cooked in a few minutes: while the extraordinary feature of the experiment was that the animal showed no symptoms of pain, although, some days afterwards, the hind legs were detached, leaving stumps perfectly cicatrised. The current reached the limbs through the intervening media of two liquid baths, which remained cold. That experiment was the primordial one of electro-coagulation.

The thermal effects of high-frequency currents were subsequently studied, in England by Sommerville; in Holland, by Wertheim-Salmonson; in France, by Zimmern and Turchini; etc. Then, all of a sudden, on the pronouncement of the German school, V. Zeyneck, of Prague, having signalised for the first time the thermal effect of high-frequency currents, Berndt, of Vienna, sought to make considerable quantities of heat to penetrate into the tissues by means of high-frequency currents. He gave his procedure the name of thermo-therapy, and utilised it clinically in the treatment of cases of sciatica, arthritis, etc. At the same period in Berlin, Nagelschmidt studied a new method of application of high-frequency currents, under the name of transthermy. He prepared a new apparatus, and succeeded in attaining to 2 or 3 ampères in local applications. He attributed the elevation of temperature which was produced to the Joule effect; and suggested, as indications for application of the new method, all those cases in which heat had been previously employed as a curative agent.

Heating by the use of high-frequency currents can be realised in three different ways—

(*a*) If we derive a collateral current from the primary solenoid of the high-frequency generators, and interpose an incandescent lamp in this current of derivation, the latter gives light. If, instead of an incandescent lamp, we place in the circuit the body of a living person and a milliampère-mètre, the subject of this new experiment feels a more or less notable impression of heat at the seat of entrance of the current, and the ampèremètre reveals intensities of 100, 250, 500 milliampères, or even more. The ports of entrance and of exit of the current are in this experiment provided by a flat electrode, spongy or metallic, and of more or less considerable surface area. In a case in which we desire to subject an articulation to the thermal influence, the electrodes are placed on diametrically opposite sides of the circulation; when we want to have the thorax traversed by the current, one electrode is adjusted on the dorsal spine, and the other on the sternum. Such is the procedure which we formerly designated the direct application—that which utilises diathermy.

(*b*) We may, however, provide one electrode of sufficiently small dimensions to give the current beyond it a considerable intensity. The special effects of this mode of application have been utilised in producing carbonisation and coagulation of the living tissues; the procedure has been designated electro-coagulation.

(*c*) One of the most usual modes of application of high-frequency currents consists in placing the subject on a specially prepared long couch formed of a dielectric substance (sheet of indiarubber or ebonite), duplicated with a sheet of tin connected with one of the poles of the solenoid. The subject of experiment holds with the hand a bar which connects him with the other pole of the solenoid. The system so arranged forms an electric condenser. (When a condenser is interposed in the course of an alternating current, the latter is not arrested, as would happen in the case of a continuous current). The body of the person experimented on then represents one of the armatures of the condenser; and, in consequence of this fact, is submitted to a series of alternate charges and discharges of very high frequency.

Regarded from our view-point, the application of the condenser couch is but a form of diathermy. The Joule effect is found in the more or less pronounced sensation of heat experienced in the wrists or forearms, and which continues, with progressive increase during the whole time of the passage of the current. The heating may often be so effective as to throw the individual into a perspiration.

With the use of a galvanic current, the lines of flow in the same homogeneous medium pursue divergent directions. But in diathermy, as Nernst has demonstrated, the distribution occurs in the same rectilinear course. Thus, when we pass a diathermic current through a piece of meat between two metallic electrodes with circular surfaces, we see by the outlined form of the coagulated mass that the current has limited its passage to a cylinder of which the extremities are formed by the surfaces of the electrodes. But, in case of a living organism submitted to the action of the current, the distribution of heat is a more complex condition. It is certain that, if we consider the case of a serial chain of different tissues—skin, cellular and fatty tissue, muscle, etc.—arranged end to end in unbroken linkage, and with an efficacious intensity of current identical at all points of the circuit, the heating of each constituent tissue of the chain should be proportional to its resistance. But, instead of this physically ideal state of things, no sooner has the current traversed the skin than it proceeds to distribute itself along lines of flux of which we do not know the degree of "physiological concentration," but which, according to all probability, adapt themselves to the pathways of least resistance. Accordingly, it is the tissues and organs of least resistance—that is to say, the best conductors—that will transmit the proportion of current which possesses the greatest intensity; and, which, accordingly, will be most heated during the passage. Thus, as the bones transmit but a very small fraction of the total intensity, they will be but very slightly heated. All the liquid tissues, on the contrary, which transmit the current will have their temperature very appreciably elevated. With regard to the circulation, it has the inevitable effect of conveying a portion of the heat locally produced to distant parts of the body. Bergonié and Réchou have conducted experimental measurements on the thigh of an ox, and have determined, with the aid of thermometers placed at regular intervals between the two electrodes, the fact that the increase of temperature was greater in the central parts; thus including the proof that the teguments must become less heated than the deep-seated tissues. At the same time, the heating of the skin is influenced by the nature and dimensions of the electrodes, for they are metallic electrodes, which are capable of dissipating a portion of the heat by the agency of calorific conductibility. Then, we have the fact that the skin, slightly moistened, also loses a part of its heat by evaporation. And, when the skin is strongly impregnated by the spongy electrodes during the transmission of the current, its temperature is raised to that of the electrode with which it is in contact, having sensibly the same conductibility as the latter; also, it loses no heat. It is for this reason that certain authorities reject their employment.

When the resistance is increased by the use of a conductor of smaller section, greater heat is produced. That is why the sensation of heat at the wrist is so notable when on the condenser couch. When we hold the bar of the couch in the hand, we actually feel that the flow of heat is passing along the length of the flexor tendons. It is also the reason that, for the purpose of heating an articulation, it is better to apply two large electrodes, one above and one below, on the periphery of the respective segments of the limb, than to pass the current perpendicularly to the axis of the latter.

PHYSIOLOGICAL EFFECTS.

The heat produced is developed in the depths of the tissues, but the individual feels it only in the plane of the skin. In diathermy, persistence of the sensory effect may continue for an interval, varying from ten minutes to one or two hours, after suppression of the current. When the temperature rises to about 45° (113° F.), the heat developed becomes painful and can no longer be tolerated. Accordingly, we cannot hope to destroy micro-organisms *in situ* by this agency; and the experiments of Laqueur on various kinds of bacilli have verified this evidence of the absence of bactericidal action.

In its local application, diathermy induces an active

hyperæmia, which manifests itself on the skin by a more or less persistent redness. This effect is, of course, also produced in the depths of the tissues. This physical feature approximates the effect of diathermy to that of the method of Bier. The hyperæmia thus provoked in the tissues augments their nutrition; and, by bringing up polynuclear cells, increases doubtlessly the power of defence against infection. Sommerville determined the fact that the cutaneous temperature of individuals subject to high-frequency currents became slightly elevated. Wertheim-Salmonson verified this fact for the case of the condenser couch, and attributed it to an augmentation of the quantity of heat disengaged. This physical change necessitates vasomotor dilatation, so that we can conceive the occurrence of lowering of arterial pressure as a consequence.

In our own researches, carried out with Turchini in 1907, we showed that this peripheral vaso-dilatation was nothing else than the defensive reaction of the organism against the advent of an excess of heat. In the normal dog, when subjected to intensities of 300 to 350 milliampères, we have found the central temperature rise three- to four-tenths of a degree (0.54°—0.72° F.) in the course of 20 minutes; on the other hand, the respiratory rhythm underwent profound modification, and increased in rate from 14 to 50 inspirations per minute. Now, we know that in the dog the essential mode of defence against heat is acceleration of the respiratory rhythm. In dealing with animals whose thermo-regulator system had been profoundly modified by the action of chloral, we have demonstrated the fact that the temperature of the animal, which invariably fell by the influence of that toxic agent, ceased to diminish as soon as the subject of the experiment was submitted to the high-frequency current.

In the normal man, the first effect of a thermal increase of any kind, whether derived from external influence, or an increase of combustion in his own tissues, is a thermo-regulator reflex: a peripheral vaso-dilatation, when the increase is slight; to which is added a transpiration, if the vital struggle has become more active. Those are the phenomena which are also observed under the influence of the contribution of heat due to the action of high-frequency currents. The organism defends itself against Joule's heat; which, with the intensity generally utilised, tends to double the thermogenesis; and thus comes to threaten the stable equilibrium of temperature. The peripheral vaso-dilatation and sweating in man, the polypnœa in the case of the dog, assure the maintenance of the normal temperature; or, at least, maintain it within certain limits; but Schittenholm, in his experiments on the dog, by the passage of two ampères during the space of one hour, saw the temperature rise to 43° (109.4° F.), and death supervene. We had already expressed the idea, in our work of 1897, that the chemical processes might undergo a transitory retardation during the passage of the current; and that under the influence of the high frequency, the organism might well economise transitorily those products which are necessary to the maintenance of its proper temperature. This hypothesis has been confirmed by Réchou; who, by analysis of the gaseous products with Bergonié's apparatus, has shown that the changes are diminished in proportion to the quantity of heat infused into the organism. Thus diathermy brings up energy of which the subject profits; and which he assimilates, inasmuch as it restrains his expenses. (*a*) This is the principle of the therapeutic method recently introduced by Bergonié under the name of "diatherm." Possibly, however, this may be true only during the passage of the current. We may ask ourselves whether the chemical processes do not undergo a subsequent reaction, and augment in intensity.

(*To be concluded.*)

DR. JAMES DODD SWALLOW, M.D., of Clifton Lodge, Clapham Park, S.W., left estate of the value of £29,454.

(*a*) With diathermal currents of extreme intensity. Nevertheless, Durig appears to have obtained a notable increase of chemical changes.

METHODS OF DIAGNOSIS IN GASTRIC CANCER. (*a*)

BY J. M. FORTESCUE-BRICKDALE, M.A., M.D.OXON.

Assistant Physician to the Bristol Royal Infirmary and Clinical Lecturer in the University of Bristol.

THE importance of early diagnosis in cases of cancer of the stomach has given rise to a large amount of clinical and laboratory work, the object of which has been to produce some test or sign so characteristic of the early stages of the disease as to make it possible for a physician to recommend and a surgeon to employ operative treatment at a time when it is likely to be of positive advantage to the patient. I propose to consider the value of the various tests which have been devised, and in order to do so it will be convenient to classify them into three main groups. In the first group I would place those tests which are applied to the contents of the stomach; in the second, those applied to the blood; and in the third, those applied to the urine.

1. TESTS APPLIED TO THE GASTRIC CONTENTS.

These may be subdivided into three smaller groups—

(1) Those which show stasis of the stomach contents.

These are three in number—namely, the absence of hydrochloric acid (1), the presence of lactic and other organic acids, and the presence of the so-called Opler-Boas bacilli.

(2) In the second group are those tests which show the presence of ulceration—namely, the various methods for demonstrating minute quantities of blood in the gastric contents or fæces (2) and the tests for serum albumen in the stomach washings (Salomon's test) (3). These tests have been introduced for some years, and their value and limitations are now well recognised (4). The demonstration of stasis or of an ulcerated surface is a valuable additional item in diagnosis, but their presence or absence is of no preponderating or conclusive significance. They may not even be early occurrences in the course of a gastric cancer, so that no special reliance can be placed on their presence or absence as indications for or against operation.

(3) The third group consists of a number of tests for alterations in the gastric contents, due to the special influence of carcinomatous growths.

(*a*) *Gluzinski's test* (5).—When an ulcer heals or becomes carcinomatous the HCl fails and a mucous gastritis supervenes. Gluzinski considers that the former occurrence is so rare as to be negligible. The stomach contents have to be removed three times on the same day and tested for free HCl and total acidity. The published cases do not seem very convincing.

(*b*) A more simple test is that for dissolved albumins (6). Wolff states that in simple achylia only a small amount of the albuminous matter in a test meal is dissolved, whereas in carcinoma a high percentage of dissolved albumin is found. The reagent used is phosphotungstic acid, prepared according to a formula devised by Wolff, and is added to a series of dilutions of the filtered gastric contents. If much albumen is present high dilutions will, of course, show a cloudy precipitate and *vice versa*. The only difficulty about the practical value of this test is that, though the findings are clear enough in undoubted cases of cancer, the border-line cases are not so easily decided. Medium degrees of dissolved albumin

(*a*) *Bristol Medico-Chirurgical Journal.*

may or may not indicate cancer. The finding of very small amounts is no doubt very much against the diagnosis.

(*c*) It has been suggested that the reason why there is often little free HCl in the gastric contents in cases of cancer is that the albumens are split up into amino-acids, which combine with more HCl than the original large protein molecule. However this may be, it seems clear that under certain conditions increased splitting of proteins does occur in cancer of the stomach, and this is the basis of the well-known tryptophane test (7). This test is apt to be interfered with by the presence of blood or bile in the stomach. Blood in dilution of 1 in 500 may upset the test, and in greater amounts certainly will do so. Regurgitation of trypsin from the duodenum and increased protein-splitting by bacterial action may also vitiate this test. Moreover, it sometimes gives a negative result in early cases, and may give a positive result in other conditions, such as ulcer and simple achylia. If a number of tests are made, however, a series of negatives may be taken as very much against cancer. Schryver and Singer (8), in the autumn of last year, published some observations showing that a ferment capable of splitting peptone occurred in numerous conditions of severe gastric disease, that it was not characteristic of cancer, and was most commonly associated with dilatation and achylia.

(*d*) The toxicity of the gastric juice to guinea-pigs has also been employed as an early test for gastric cancer. Liveriato (9) injected it subdurally, and found that whereas 1 c.c. from normal stomachs produced no symptoms, 0.1 c.c. from cancer cases was sometimes fatal. Anaphylaxis was produced by the maximum harmless dose of 0.05 c.c., which never occurred with normal gastric juice. The guinea-pigs were prepared by an injection of extract of carcinoma, and then given subdurally a small amount of filtered gastric juice, obtained three-quarters of an hour after an ordinary Ewald test meal. A marked symptom in the anaphylactic shock produced was a fall of temperature. Control experiments with normal gastric juice and with non-sensitised animals were negative. Similar re-actions have been obtained by other workers for blood serum, and not only in cancer but in syphilis, tuberculosis and other diseases. The reaction in any case appears to be against the foreign cells and not against the specific cause of cancer, whatever that may be. Embryonic cells, other neoplasms, and apparently normal sera occasionally give anaphylactic reactions in the sensitised guinea-pigs.

(*e*) Attempts have also been made to obtain specific precipitins from the gastric contents in cancer. Alfredo (10) prepared a rabbit serum by injecting cancer extracts, and this was tested against gastric juice *in vitro*. Cancer juices were found to precipitate the cancer serum, but apparently gastric juice in other conditions—*e.g.*, ulcer, may produce a similar result.

In reviewing the methods described in this group, it will be noted that they are far more specific in character than those of the first two groups. Giuzinski's test is in a way intermediate between this group and the others, as it represents a *result* of the malignant growth on the secretory processes in the stomach, which, though not specific, is somewhat characteristic. Many possible sources of error surround the tryptophane test, and in early cases it is not infrequently negative. These tests may therefore be considered not sufficiently biological in character, while those depending on the production of anaphylactic shock are, if anything, *too* biological, and do not rest on a sufficient knowledge of the underlying principles of cellular physiology.

II. Tests applied to the Blood.

Passing on to the second main group of tests, two main sub-groups will have to be considered. The first sub-group consists of tests applied to the corpuscular part of the blood, and need not detain us for long. Two diagnostic points have been suggested as of value—namely, the failure of digestion leucocytosis and the decrease in the hæmoglobin. The former is now recognised as unreliable, and the latter is not shown to occur sufficiently early to be of practical value. We can therefore go on at once to consider the tests applied to the blood serum, and it is to be noted that the general criticism levelled against all these tests is that they are most likely indications that the originally local disease has become general, and therefore that the time at which diagnosis is essentially important has gone by. In some cases this may indeed be true, but it does not altogether follow that because alterations have been produced in the blood serum therefore actual metastasis must have taken place. Nor do we know, I take it, how much "generalisation" is necessary to prevent successful surgical treatment of a primary growth. These tests, therefore, must be judged on their merits, with regard firstly to their clinical accuracy and secondly to their practical simplicity.

(1) Macalister and Ross (11) have stated that the blood of cancer patients contains a substance or substances which excite pseudopodial activity in normal leucocytes, a reaction also observed with certain alkaloids. How early in a case of cancer this reaction may be expected to occur does not appear from their original communication; and although they did not obtain any positive results in healthy persons or those suffering from diseases other than cancer, it is quite possible, as they themselves admit, that the phenomenon they describe is not really specific at all.

(2) Two tests which may next be described seem to be connected with each other in some way, though not altogether running on parallel lines. The first of these is the reaction described by Brieger, Trebing and Marcus (12), and sometimes called Brieger's cachexia reaction. Normal blood serum contains a substance which is capable of inhibiting the proteolytic action of trypsin. The serum of guinea-pigs immunised to trypsin shows this property in a much higher degree. In certain diseases also the antitryptic power of the serum varies considerably. The test is usually carried out by dropping varying amounts of trypsin solution mixed with a constant amount of blood serum on to Petri dishes filled with a solid medium made from ox serum and incubating them. Where the trypsin has acted on the medium small depressions are found, and the antitryptic action of the serum to be tested is measured by the strength of dilution of trypsin it can inhibit. Normal blood serum apparently inhibits trypsin solution in 1 to 4 dilution. The antitryptic power is much decreased during digestion and often in diabetes; it has also been found decreased in chronic Graves's disease, primary untreated syphilis, and in catarrhal jaundice. On the other hand, in pneumonia, it is increased up to the crisis, and then falls to normal as the physical signs disappear, and in lymphatic leukæmia and various blood diseases it is also increased, but not always to any great extent. In a large number of cases of carcinoma the antitryptic power of the serum is considerably increased, thus the proportion may

be 1 :10 or 1 :8 instead of the normal 1 :4. Other cases of cancer give only a slight increase, such as might be found in normal persons. Now in some patients showing an increase in the antitryptic action of the serum the increase disappears after trypsin has been given by the mouth, whereas in others a still further increase occurs and is maintained. This latter reaction is taken to indicate a rather worse prognosis. Brieger considers that the increased antitryptic power of the serum is a measure of the cachexia induced by the disease. It is not specific for cancer, as it occurs in other chronic cachexias, but it may be of value in prognosis, and a negative result of the test is against the presence of cancer.

(3) The next test is that described by Shaw-Mackenzie (13)—namely, the increased power of activating the fat-splitting pancreatic ferment which is possessed by the serum of carcinomatous patients. According to his observations, human and animal serum itself has no lipoclastic or fat-splitting action, but is capable of activating pancreatic lipase. This activating power is much increased in carcinoma and in certain other diseases, such as diabetes and possibly tuberculosis. This reaction which, unlike the antitryptic action, has an accelerating and not an inhibiting effect, is also unlike it in that it persists after recovery or removal of the growth, whereas the antitryptic power sinks to normal under these conditions. The lipase, according to Rosenheim's experiments, consists of two parts, which may be separated by filtering a glycerine extract of pancreas. The solid residue is inactive and the filtrate almost inactive, but mixed together they are active. The solid residue is thermolabile, and may be activated not only by the thermostable filtrate, but by normal blood serum and to a still greater extent by carcinomatous blood serum. The activity is measured by titration of the fatty acids produced. Shaw-Mackenzie believes that this reaction, together with the antitryptic, are strong evidence of the presence of cancer, while their absence excludes it. It is, however, not yet clear whether these reactions are constantly present in the very early stages of the growth.

(4) Freund and Kaminer (14) noted that normal serum contained a substance which dissolves cancer cells, whereas serum from patients with carcinoma failed to do so. This reaction, however, is not constant, and there are considerable difficulties in obtaining a suitable emulsion of cancer cells. Monakow found that sera of all cancer cases showed a destructive action on cancer cells in at least one-fifth of the cases. Other diseases give the reaction in at least 15 per cent. of the cases, and in three early cases of cancer it was only positive in one (Kraus, Graff and Ranzi).

(5) Cancer serum has also been found in certain cases to dissolve normal red corpuscles, though not those of the patient (15). This reaction is again not constant, and has been calculated to be present in only about 40 per cent. of the cancer serums. A similar reaction, though apparently to a lesser extent, has been shown to occur in tuberculosis and in other diseases. The hæmolytic action is destroyed by heating to 50 deg., but after heating the activity is restored by admixture of fresh normal serum. The reaction, therefore, appears to be due to a substance belonging to the class of bodies like the solid residue of pancreatic extract above described, that is to the amboceptors or immune bodies. It has been named isohæmolysis. A modification of this test, in which the hæmolysis is made to take place subcutaneously by injecting a suspension of normal corpuscles under the skin of the cancerous patient, was introduced by Elsberg and others in 1908. Various changes took place within a few hours at the site of injection, which was said to be characteristic of cancerous hæmolysis. The originators claimed 77 per cent. of positive results in cancer, but Risley, who repeated their experiments, only got 33.5 per cent. of positive results in cancer, while only 75 per cent. of non-malignant cases were negative. Moss investigated the natural hæmolysins, and found that though not present so generally as the agglutinins, they seemed to be governed by similar laws. Considerable variation in agglutinative power of normal serum and in responsive reaction to agglutinins in red corpuscles occurs in different individuals; some sera contain no agglutinins, and some corpuscles never agglutinate. Other sera will only agglutinate certain corpuscles, and again, some corpuscles can only be agglutinated by certain sera. Gorham and Lissen have shown that these conditions also apply to a great extent to hæmolysis. By using Elsberg's method they obtained 60 per cent. positive results in cancer and 88 per cent. negative results in non-cancerous cases. The patients were tested with four different groups of corpuscles. They consider that the hæmolytic test is certainly not specific, and that the results obtained by test-tube experiments are quite different from those obtained by the subcutaneous method. Considerable importance attaches to the sort of corpuscles used, owing to the varying capacity for agglutination in the corpuscles of different individuals. They find positive reactions more significant than negative, but note that at present there is no evidence of the value of this test in doubtful or border-line cases.

(6) The complement deviation method has also been extensively tried in cancer with somewhat confusing results. A large number of synthetic antigens have been tested, as well as various antigens prepared from malignant growths. The synthetic lipoids give equally strong reactions with malignant and non-malignant cases, and the various methods for preparing antigens from tumours or pancreatic extracts give bodies which are neither stable nor specific. In particular it has been found impossible to differentiate syphilis from cancer by this test.

(7) The remaining test in this group is that known as the meiostagmin reaction (17). Traube showed that the addition of a toxin to an antitoxin caused a diminution of surface tension, and consequently that the size of a drop of the liquid was diminished and a given volume of the fluid would yield an increased number of drops. The instrument he devised for measuring the drops is called a stalagmometer, and consists of a finely-graduated pipette with a central bulb, holding about 8 c.c. The lower end forms a capillary tube, the extremity of which is ground flat and has a diameter of about 7 mm. When full it contains a constant number (about 56) of drops of distilled water at 15 deg. C., and all the drops, which can be counted as they fall from the ground base, are of equal size. Fractions can also be estimated. Ascoli first applied this principle to typhoid sera. The diluted serum was mixed with a fixed quantity of alcoholic extract of B. typhosus and the number of drops immediately counted. The preparation was then incubated for two hours, cooled, and the drops again counted. With very dilute antigens there was an increase of two or three drops, but no increase was obtained with normal sera nor with an antigen prepared from B. coli. Similar results were obtained in syphilis, and the reaction was then extended to cancer. The main

difficulty in this test as applied to cancer is the preparation of the antigen, which appears to be a lipoid body. Several methods have been adopted from time to time, and it has been shown that only a certain proportion of cancerous tumours are suitable for preparing it, and it is not very stable. The most recent antigen is a methyl alcohol extract, which is titrated against normal serum, the weakest dilution which fails to give an increase of more than one drop with diluted normal serum being used. Stronger dilutions of the antigen are unreliable, because they give a positive reaction with normal sera.

As to the specific character of this reaction, it has been shown that a positive result can be obtained occasionally in other diseases, such as diabetes, tubercle, febrile and septic conditions, but it is not a cachexia reaction. This appears to be the most satisfactory of all the laboratory tests; the main difficulty consists in obtaining a satisfactory antigen. Ascoli and Izar obtained a positive reaction in over 93 per cent. of cancer cases, Verson in 55 per cent., Stabilini in 100 per cent., Kelling in 47 per cent., Michaeli and Cattoretti in 87 per cent., and Stammler in 73 per cent. The last named also obtained a positive reaction in 20 per cent. of non-malignant cases. Tadesco obtained 93 per cent. positive in malignant disease and 12 per cent. positive or doubtful in other cases. Kraus and others got 92 per cent. positive in malignant cases.

Stammler has modified this test, and instead of using the drop reaction, relies on the formation of a precipitate when the antigen is incubated with the patient's serum. He obtained 83 per cent. positive results with cancer cases and 14 per cent. with other diseases.

III. Tests applied to the Urine.

I now pass on to consider those tests which are applied to the urine. These are all devised with a view to showing either that certain changes of metabolism have been set up by the cancerous process which can be recognised by the chemical character of the excretions, or that certain ferments are being excreted as a concomitant of the cancerous condition, which are not present to the same extent in health.

(1) The first of the latter group is the presence of a reducing ferment in the urine capable of decolourising methylene blue (18). This test has the advantage of extreme simplicity, for all that is necessary is to mix the urine with the ordinary solution of methylene blue and leave it to stand in a warm place for some hours. If the colour is destroyed a reductase is present and the test is positive. The disadvantage of this test is that it has been shown to be quite unreliable, as all cancer cases do not give a positive result and many other conditions do.

(2) More complicated is the determination of the proteolytic ferment in the urine (19). The method used consists of incubating the clear urine in various concentrations with a dilute solution of ricin, which has been precipitated with decinormal hydrochloric acid. However, the published results are contradictory, for two reasons—firstly, that different experimenters have adopted different methods; and secondly, that in many cases the clinical diagnosis has not been confirmed. In cases of simple achylia urinary pepsin may be low or high as compared with gastric pepsin, and in some cases of cancer it is present in large amounts in the urine. On the other hand, it may be absent completely in achylia at certain times. Some cancers also show complete absence of urinary pepsin. Thus, though pepsin in large amounts in the urine may point to cancer, the results on the whole are too variable to be of clinical value, and it is especially in early cases that these variable results are obtained.

(3) A large amount of work has recently been done on the urinary nitrogenous bodies in relation to cancer. It seems clear that under certain abnormal metabolic conditions there are variations in the form in which nitrogen is excreted, but so far the results do not seem sufficiently definite to be of great value.

The principal methods which have been suggested are:—

(*a*) Precipitation with 5 per cent. phosphomolybdic acid. The urobilin must be removed by washing the precipitate with absolute alcohol. The occurrence of a precipitate is only suggestive of cancer, and only occurs in about half the cases (20).

(*b*) Increase in the proportion of nitrogenous substances precipitated by alcohol. This is known as Salkowski's test or the colloidal nitrogen test (21). An increase in the proportion of colloidal nitrogen was considered diagnostic of cancer. Later, instead of alcohol, salts of the heavy metals, such as subacetate of lead or zinc chloride, were used as precipitants after removing the albumin with baryta mixture. Lower values are obtained by this method. Confirmatory evidence of the value of these methods is wanting, the conclusions of other authors being summarised as follows:—

(i) Higher values of colloidal nitrogen are not specific for cancer. Not only do some cases give a low percentage of colloidal nitrogen, but there is a large series of cases, especially cirrhosis of the liver, diabetes, and infectious fevers, which give more or less constantly high figures.

(ii) With these exceptions it is true that cancer cases on an average give a higher percentage than healthy persons or non-cancerous cases.

(iii) The condition of nutrition, the food and the nitrogen balance influence the result of the test.

(*c*) A similar method is the estimation of the polypeptids in the urine (22). The amino-acids are first estimated by formalin titration; the polypeptids are then split up by means of strong HCl, the acid removed, and the resulting amino-acids again estimated. The difference gives the amount of polypeptids. Although polypeptids on an average are increased in cancer, yet this method is open to the same criticism as the last.

(*d*) A peculiar group of polypeptids—namely, the oxyproteinic acids (23), have also been found to be increased in cancer. The method for their estimation by Solomon and Saxl depends on their sulphur content. The method is very elaborate, as the inorganic sulphur and ethereal sulphates have first to be removed, and the polypeptid sulphur then oxidised by perhydrol or sodium nitrite. This reaction has now been applied to about 223 cases, with positive results in about 70 per cent. It does not appear to be due to cachexia; it also occurs in other conditions (5 per cent.), but it seems to appear early in cancer cases. The elaborate technique is against its general adoption.

(4) A reaction differing somewhat from those in the last group was described in 1910 by Royle (24). She found that in cancer patients the ratio of the urinary phosphates to the uric acid was decreased, that is to say, that on a standard diet the excretion of phosphates decreased and the excretion of uric acid increased. As yet the results have not been confirmed on a large scale, but the reaction appears to be so similar to those

previously described that it seems probable that it will be shown to be dependent on some condition frequent in cancer, but common to it and certain other disordered states of metabolism. The examination of the urine cannot be said to have hitherto provided a satisfactory aid to the diagnosis of cancer. The methods are for the most part complicated and the tests have in no case been shown to be pathognomonic. They appear to occur early in the disease, however, and to be dependent on metabolic changes other than mere cell destruction or cachexia. As far as the results hitherto obtained go, a positive result from the meiostagmin reaction and the method of Solomon and Saxl for estimating the oxyproteinic sulphur would seem to give a very strong presumption in favour of cancer, provided that certain other conditions can be otherwise excluded. On the negative side, an absence of increase in the antitryptic power of the serum and an increase in the lipoclastic accelerators is against the presence of malignant disease.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

STRICTURE OF THE URETHRA.—MR. WILLMOTT EVANS operated on a man, æt. 43, who had suffered from stricture of the urethra for more than ten years. He had had increasing difficulty in micturition, and on two occasions he had had complete retention of urine. He had been relieved on each occasion by the passage of a catheter. Five days before admission he had a further attack of retention of urine. An attempt had been made by a private doctor to pass a catheter, but in vain, the only result being the production of great pain and the passage of blood from the urethra; therefore he was sent to the hospital. As a catheter could not be introduced into the bladder after a short trial, the bladder was aspirated above the pubes, and four pints of clear urine were drawn off. A saline aperient was then given, and the next morning the patient was able to pass water, though with some effort. It was decided therefore to operate. The urine, the specific gravity of which was 1,012, contained a trace of albumen. The patient was anæsthetised and placed in the lithotomy position, the perinæum was shaved and painted with a 2 per cent. solution of iodine. A Wheelhouse's staff was introduced down to the stricture, which was situated in the membranous portion of the urethra. With a scalpel an incision was made into the groove of the staff about half an inch in front of the stricture; the staff was then turned round so as to draw towards the anterior part of the incision; the margins of the opening into the urethra were then seized with tissue forceps. In this way a diamond-shaped opening was formed, through which was passed a probe-pointed director. With only a little difficulty this was passed through the stricture, which was laid open by a scalpel running in the groove of the director. The probe-pointed gorget was then passed in the direction of the bladder through the opening, and a gum-elastic catheter was introduced through the meatus, brought out at the perinæal opening, and then, by means of the gorget, passed back into the bladder. By means of two stitches the sides of the wound in the urethra were brought together, but the skin wound was not sutured. A gauze dressing was applied.

Mr. Evans said that the long duration of the disease made it extremely probable that the kidneys had suffered from the effects of long-continued pressure, therefore he considered that in such a case it was far better to do an external urethrotomy, which would cure the obstruction at once, than to endeavour by the slow process of dilatation to relieve the stricture. The Wheelhouse operation was probably, he thought, the best method of external urethrotomy for impermeable stricture. It was essential, he pointed out, not to open the urethra too close to the stricture, otherwise the difficulty of finding a way to the stricture was much increased. The catheter may remain *in situ* for 48 hours before being changed, and it is usually not difficult to introduce another catheter provided that the catheter has a good curve on it, so that its point remains in contact with the upper wall of the urethra. The urethra nearly always, he said, required some stitches. The superficial wound need not be closed.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DECEMBER 12TH, 1913.

The President, DR. M. J. GIBSON, in the Chair.

CARCINOMA OF TUBE AND OVARY.

DR. GIBBON FITZGIBBON showed a specimen which consisted of the left tube, the right ovary, and the uterus. The history of the case was:—Mrs. O. D., æt. 40, ii.-para, five years since last confinement. In November, 1912, the patient was first seen, complaining of profuse metrorrhagia, which had been occurring every fortnight or three weeks for about three months, and lasting ten to twelve days. She was curetted for the purpose of diagnosis. The uterus was very little enlarged. The cavity was $3\frac{3}{4}$ inches, with nothing abnormal to be felt in its shape. The appendages were apparently normal. She left hospital in twelve days, and when seen two months later the menses had occurred normally twice since the curettage. She remained quite well till July, 1913, when she commenced to have pains in pelvis and abdomen, but did not come to be seen till October, 1913. She was then looking very ill, had lost flesh, and was very anæmic. On examination, a tumour was found in the middle line reaching to within one inch of the umbilicus. The uterus could not be definitely separated from this tumour, and there was a large mass behind the uterus filling Douglas's pouch and rather fixed, but separate from the tumour in front. The condition suggested multiple fibroids, except that the front tumour was distinctly cystic. At the operation the right ovary was found cystic, about the size of a fœtal head and adherent to the fundus of the uterus and intestines. This was first removed, and then the left tube, which was enlarged to about the size of a cricket ball. The ovary showed pathologically a carcinoma of a squamous type and rather suggestive of sarcoma. The

tube was solid, and proved to be a columnar carcinoma quite unlike the ovary. A nodule on the uterus rather resembled the ovarian cancer. The combination of two distinct types of cancer in the tube and ovary at the same time was curious

STRANGULATED PYOSALPINX.

The PRESIDENT showed a specimen of strangulated pyosalpinx of large size. The symptoms developed suddenly, evidently as a result of the sudden strangulation. The condition was probably of tuberculous origin.

Sir WM. SMYLY asked if the pus was examined for tubercle bacilli. The fact that the patient had no symptoms until the tube became twisted would bear out the idea of tubercle, if they were tubes which had become infected; otherwise he considered there would have been symptoms. He had seen twisted tubes before, but when he got them they were of old standing. He had never met with a case of acute strangulation.

Dr. SPENCER SHEILL considered the weight of evidence in favour of tuberculous tubes, but failed to see how the condition was brought about without some disturbance of function in ovaries and uterus.

NOTES OF SOME RECENT CASES PRESENTING POINTS OF SPECIAL INTEREST.

Dr. SPENCER SHEILL read notes and observations on several cases, including eclampsia; epidemic gastro-enteritis in infants with reference to the milk supply as a cause of the condition; depressed fracture caused by contracted pelvis during labour and the method of raising the depression with bullet forceps.

Dr. TWEEDY said he would like to hear Dr. Sheill's views regarding bleeding as a treatment for eclampsia. He had never been able to see the *rationale* of this. It had been suggested that it removed poisons from the blood, but this he considered hypothetical. He submitted that there was no reasonable foundation for bleeding unless an equal amount of fluid was put back. A salt-free diet was considered good for certain inflamed conditions of the kidney, and yet it was suggested in this case to introduce salt. It appeared to him more reasonable to dilute the fluid put into the blood in such a case with carbonate of soda. With respect to the fracture of the skull, he thought that the difficulty experienced was due to the bullet forceps not being sharp enough. He mentioned a case in which he removed a very deep depression in the skull of a child, aged two years, with the assistance of three bullet forceps, all three being pulled upon at the same time.

Sir WM. SMYLY referred to a series of pictures of bottle dairying which he had recently seen; the system appeared to be perfect, and he wondered something of the sort was not introduced into this country. He had never seen any reason to believe in the theories put forward regarding maternal impressions. He believed in the bleeding treatment for eclampsia. It had always been well spoken of by those who had experience of it. He suggested that in eclampsia it was known that the blood was of high specific gravity and contained less water than usual; that it clotted all over the body, and that the arterial tension was very high, and patients often died of apoplexy. The arterial tension was reduced by bleeding and apoplexy prevented. He considered the great difficulty in knowing anything about the treatment of eclampsia was that even with an enormous number of cases no very definite conclusions could be formed.

Dr. SOLOMONS considered that one of the most interesting points raised in the paper was the treatment of eclampsia in private practice. There was no doubt that a maternity hospital was the best place for these cases in order to ensure a satisfactory result, and unless the practitioner could devote all his time to the eclamptic patient she should be sent to one of these institutions. It was probably a coincidence that he had seen eclampsia developing in several patients who had become pregnant after operation for sterility, and he suggested the possibility in the future of some test in order to find the fitness or unfitness for pregnancy of sterile women. He still used scopolamine-morphine anæsthesia where the case was suitable and there was a reliable nurse. He was somewhat diffident about vaccination, as he had seen various minor ailments develop after a careful aseptic inoculation. As regards maternal impressions, Dr. Wrench, in his work, "The Healthy Marriage," advised that pregnant women should live in the happiest surroundings in order to bear a happy child. He (Dr. Solomons) believed strongly in this advice.

Dr. FITZGIBBON believed in bleeding in eclampsia if used in suitable cases. A large number of cases occurred in full-blooded women, and such reacted favourably. The system of introducing saline under the breast had the effect of lowering the specific gravity of the blood. He considered that Dr. Sheill took too severe a view of the responsibility of the medical profession as regards contaminated milk. Both summers referred to by him were somewhat similar in the matter of temperature, and also in the difficulty of keeping milk; he did not hold with the idea that most of the cases of enteritis resulted from the milk as supplied by the dairies. He experienced several cases in which he attributed the infection to the way in which the milk was kept in the household, and suggested that much of the contamination took place after the milk was received into the house. He considered that more could be done by educating the people than by attacking the dairies, although he recognised that the latter were far from perfect, and could be very greatly improved by enforced supervision.

Dr. ROWLETTE, referring to the serious outbreaks of gastro-enteritis, said he believed that most of the disease was due to contamination of the milk after it left the dairy. He attributed the disease to two factors—contamination by flies and contamination by dust. The suggestion of conveying the milk in sealed bottles he looked upon as impracticable for the poorer classes, but considered the matter should be taken in hand by the public health authorities, and that rubbish heaps should be cleared away from the back lanes and courts of the city, and that the streets should be kept clean.

Dr. TREVOR SMITH drew attention to the difficulty sometimes of bleeding patients suffering from eclampsia. He recognised that where the right side of the heart was overloaded, bleeding was of the greatest use.

Dr. SHEILL, in reply, said that the milk supplied was contaminated before reaching the consumer, but he also thought it got very much more contaminated afterwards; and even supposing the milk to be supplied sterile to the consumer, one fly might introduce sufficient damage to kill any child. He did not agree that the putting of saline under the breast had the same effect as bleeding, as saline absorbed into the blood might be as rapidly excreted, whereas in bleeding some of the solid matter of the blood was withdrawn and also some of the poisons. He was convinced that the blood in these cases was toxic, and that the removal of some of it would reduce the pressure and also some of the toxins. Altogether, he thought that the weight of evidence went to show that bleeding in eclampsia was a good procedure. In the fatal case the ether was given in the ordinary way without nitrous oxide and the total amount of ether was never up to that marked "full" on the Clover's inhaler. Everything that could be thought of was done for the patient, and mouth-to-mouth insufflation was done regularly for over an hour.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DECEMBER 18TH, 1913.

The President, MR. ROBERT JONES, F.R.C.S., in the Chair.

MR. R. E. HARCOURT related the case of a man, æt. 19, in whom hypermetropic astigmatism was present, with hystero-epileptic fits and headaches over a period of six weeks. Rest in bed caused the fits to almost cease, and correction of the refractive error resulted in complete cessation of fits and headaches.

Dr. H. ARMSTRONG mentioned the case of a child of

four in whom homicidal mania was present along with hypermetropia and squint. In this case correction of vision had also resulted in complete disappearance of all mental symptoms.

Mr. A. NIMMO WALKER read a note on further experiences of

SCLERO-CORNEAL TREPHINING FOR GLAUCOMA.

Mr. Walker described three important modifications of the operation originally performed by Lieut.-Col. Elliot. The flap was altered in shape, being made a small segment of a large circle parallel to the limbus; the trephine hole was made further forward, and the iris was allowed to prolapse into the trephine hole, a small portion being snipped out with scissors, and the prolapsed portion allowed to fall back into its place. Mr. Walker was of opinion that this operation was by far the best treatment yet discovered for glaucoma. He did not claim that it was an infallible cure for all cases, but it enabled the surgeon to advise an operation which had a good chance of arresting the disease without causing mutilation of the eye or damage to the sight. A patient was shown on both of whose eyes the trephining had been performed.

Mr. R. J. HAMILTON had seen two cases where the drainage had not continued after the trephining and iridectomy had then been done. He had had good results in other cases.

Mr. HUGH E. JONES had found iridectomy satisfactory, but considered that in some cases tension was kept down better by trephining.

Mr. EDGAR STEVENSON considered that the introduction of the trephining operation was the most important step forward in ophthalmology since Von Graefe introduced iridectomy. The operation was all-British.

Dr. BLAIR BELL described a new operation for the

TREATMENT OF SEVERE SALPINGITIS

in young women. As the internal secretions of the ovary and the menstrual function were important in the general condition of young subjects, he did not in them approve of complete removal of the tubes, ovaries and uterus. By taking a wedge-shaped portion of the fundus along with one ovary and both tubes, he removed the diseased structures and left enough to be of use to the patient.

Dr. C. O. STALLYBRASS read a paper on

SOME FACTORS IN THE SPREAD OF TYPHOID.

Dr. Stallybrass showed by large charts that the great fall from 1,300 cases in 1895 to 124 in 1912 was coincident with the fall in the number of courts and alleys in the city. The greater facilities for the isolation of the sick, the supervision of the milk supply and that of other foodstuffs, and the removal of fly-breeding refuse had also contributed. Many cases were imported, mainly sea-borne, and these might be the source of small local outbreaks, especially where one of the patients was a chronic carrier. Dr. Stallybrass had found shell fish cases to be due mostly to mussels from Ireland. Oysters had not for some time given rise to typhoid so far as was known. In Dr. Stallybrass's opinion typhoid was chiefly spread by direct contact, fingers of a patient or his attendants being soiled by excreta, and in many cases food prepared by the soiled hands leads to spread of the disease. He thought it possible that flies might carry germs to food and so cause infection. It might yet be proved that biting insects also spread the disease.

Dr. E. W. HOPE said Dr. Stallybrass's careful work proved and confirmed the views of the causation of typhoid fever. It had been suggested that the disease was decreasing because the population was acquiring immunity, but the facts presented proved this was not the case; 65 per cent. of modified cases had had their origin determined accurately.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD IN MANCHESTER, DECEMBER 19TH, 1913.

The President, DR. W. E. FOTHERGILL, in the Chair.

DR. DONALD (Manchester) showed a specimen of endothelioma of the cervix occurring in a woman, æt. 25, removed by abdominal pan-hysterectomy.

Dr. BLAIR BELL (Liverpool) showed a specimen of an unusual malformation of the uterus. This uterus was apparently normal except for a small left horn to which were attached the round and ovarian ligaments. Also a specimen of an ampullary pregnancy on the point of rupture.

Dr. CLIFFORD (Manchester) reported a case of concealed accidental hæmorrhage, accompanied by hæmorrhage into the peritoneal cavity, apparently due to rupture of vessels in the right broad ligament following the great and acute distension of the uterus. The patient was admitted to hospital in a very serious condition, and after a short rest it was decided to open the abdomen and remove the uterus. This was rapidly done, and for a short time the patient rallied, but eventually died six hours after the operation. The urine was loaded with albumen.

Dr. LEITH MURRAY (Liverpool) and Dr. LITTLER (Southport) recorded a case of adeno-chondro-sarcoma of the endometrium, occurring in an unmarried woman æt. 46. Microscopical examination of a polypus suddenly extruded from the cervix rendered the diagnosis easy, and a wide hysterectomy was done. Regular glands, sarcoma spindles, islands of hyaline cartilage and possibly fat cells were present. There was no invasion of the cervix, the musculares of the body, or the appendages.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the ninth meeting of the Royal Commission on Venereal Diseases, which was held on December 15th, evidence was given by Mr. J. Ernest Lane, Senior Surgeon of St. Mary's Hospital and of the London Lock Hospital, and a member of the Royal Commission. Mr. Lane said that in his opinion venereal diseases are attended by just as great a mortality as tuberculosis or cancer, and although it was not possible to obtain figures to support this view it was one which had been more or less frequently expressed by well-qualified persons. He thought that the diseases were somewhat less prevalent than twenty or thirty years ago, but on this point it was very difficult to speak with certainty; the statistics of deaths certified as due to syphilis did not give any idea of the prevalence of the diseases. Mr. Lane remarked that although large subscriptions are given to the cause of combating other diseases nothing has been done with regard to venereal diseases, and public money has never been expended except in carrying out the Contagious Diseases Acts. He laid stress on the necessity for improved and free hospital treatment, and said that every patient suffering from any form of venereal disease ought to be entitled to gratuitous treatment and medicine and to bacteriological and other tests. If it is desired to cure syphilis and get rid of the disease, anything that would aid early diagnosis ought to be at a patient's disposal without expense to him. In any scheme for the efficient treatment of the diseases, the establishment of night clinics was essential.

On the subject of notification, Mr. Lane said that though he had formerly been in favour of notifying all cases of venereal disease to the sanitary authority, he had now modified his view because he was convinced that notification would deter sufferers from seeking proper advice, and would lead to increased recourse to quack treatment.

Dealing with the question of the education of public opinion with regard to venereal diseases, he said that in the first place the infected person must be instructed. It should be made compulsory for medical practitioners to supply to every patient suffering from venereal disease printed instructions as to the nature of his disease and as to the measures he should adopt to avoid spreading the trouble; copies of these

instructions should be supplied gratuitously to the doctors. Secondly, he would suggest that all institutions where there are a large number of employees or institutions, such as colleges and universities, ought to have some course of lectures explaining the dangers of venereal disease. It was also of the greatest importance that the standard of knowledge of these diseases in the medical profession should be raised; in the past the teaching given in the medical schools was very inadequate, but steps were now being taken in some of the more important hospitals which should lead to an improvement in this respect.

Mr. Lane gave some statistics of the work done at the London Lock Hospital. He showed that during the last thirty years there had been a remarkable diminution in the numbers of prostitutes treated at the Female Hospital; at the present time, the majority of the female patients were very young girls, and 13 per cent. of the patients were married women. All the cases in the children's wards and the greater part of the married women were examples of innocent syphilis. In the Male Hospital, the new out-patient department opened in 1911 had proved most satisfactory, and the number of attendances was increasing; a new in-patient department was opened in November last with three wards perfectly fitted with all modern accommodation for 40 patients.

At the 10th meeting held on December 19th, Dr. Stevenson, Superintendent of Statistics to the Registrar-General of England and Wales, attended and gave evidence supplementing that which he gave at the first meeting. Dr. Stevenson said that though the statistics tabulated from death registers by the Registrar-General cannot be claimed to afford any measure of the absolute amount of mortality from venereal disease, they do throw light in varying degree upon its relative amount, whether the comparison made be historical, geographical or social. Looking at the matter from the historical point of view, the curve of mortality from syphilis in England and Wales shows a very large and rapid rise between 1850 and 1868, followed by a period of fairly sustained elevation till about 1886; this is succeeded by ten years of rapid fall, and the fall has continued, though it has become less rapid, since 1896. Dr. Stevenson was of opinion that the fall recorded in the last thirty years represented a genuine decrease in the mortality from the disease; he gave several reasons in support of this view and referred also to the large contemporaneous fall in the curves showing prevalence of syphilis in the Army and Navy.

To illustrate the incidence of syphilis and diseases resulting from it on various occupational and social classes, tables had been prepared in which the male population was graded according to occupation into five main groups and three additional groups (textile workers, miners and agricultural labourers), representing the three largest single industries. Of the five main groups, the first consisted of the upper and middle classes, and was sufficiently comprehensive to include clerks and insurance agents, the fifth group represented unskilled labour. The most striking feature of the tables was the uniformly low mortality of textile operatives, miners and agricultural labourers, the last group especially yielding very low rates. Of the five main groups the highest mortality was found in group 5; the mortality from syphilis was lowest in group 1, but the mortality recorded against it from the parasyphilitic diseases was high, and for locomotor ataxy the rate was higher than that of any of the other groups,

Taking all the circumstances into consideration, Dr. Stevenson conjectured that syphilis is most prevalent amongst the highest and lowest of the five social classes he dealt with, and that the three great industries of textile manufacture, mining and agriculture are almost certainly exceptionally free from the disease. With regard to the geographical distribution of the disease, the tables furnished by Dr. Stevenson indicated that the prevalence in the large towns was much greater than in the rural and small urban districts.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 3rd, 1914.

TREATMENT OF PSORIASIS.

THE treatment of psoriasis is internal and external, and requires equal attention. It is well known, says Prof. Gougerot, that auto-intoxication plays an important *rôle* in the development of cutaneous affections, hence the necessity of submitting a patient with psoriasis to general treatment, taking into account the constitution of the individual. If he is of arthritic, gouty, nervous, dyspeptic temperament, the treatment will vary accordingly, but, generally speaking, a lacto-vegetarian *régime* more or less severe, according to the intensity of the eruption, will be ordered.

As to drugs, excepting arsenic, they are practically useless. Arsenic in the form of Fowler's solution, Eau de Bourboule or arseniate of soda, may be given in judicious doses. Extract of the thyroid gland has been prescribed of late years with some success.

It would be well to remember that these patients are considerably dimineralised; consequently it is necessary to furnish salts of lime, chloride of sodium, phosphates to the system.

Carbonate of lime, 10 grs.
Phosphate tricalcic, 7 grs.
Magnesia cal., 1 gr.
Chloride of sodium, 1 gr.

For one cachet, three daily.

The local treatment, which is very important, cannot be identical in every case. According to the intensity and more or less great extent of the eruption, and, above all, according to the more or less integrity of the emunctories, the treatment employed will be more or less energetic.

For instance, in cases of generalised psoriasis with large red patches indicating great irritability of the tegument, the treatment should not be too active. The medical attendant will content himself with prescribing anodine ointments (oxyde of zinc) and starch baths. When irritation has more or less subsided, a more energetic treatment may be instituted. As a commencement, a weak cadic ointment is applied:—

Oil of cade.
Oxyde of zinc,
Talc powder,
Oil of sweet almonds, aa.

After a few days of this treatment, the reductive ointment of Gaucher may be prescribed:—

Sulphur, 15 grs.
Camphor, 15 grs.
Salicylic acid, 15 grs.
Oil of cade, 3 drs.
Oxide of zinc, 5 drs.
Vaseline, 1 oz.

The patient will apply it at bedtime, and wear drawers and a jersey, which he will change but once a week.

In the morning he will remove the ointment with soap and take a bath as follows:—

Oil of cade, 4 oz.
Black soft soap, 1 oz.
Water, 1 pint.

To be added to the bath.

The patient will remain as long as possible in the bath, half or three-quarters of an hour, after which he will dry himself and proceed to his occupations. At night the ointment is to be re-applied.

At the end of 10 or 12 days of this treatment the condition of the patient is much improved; a certain number of patches have paled out, the eruption has diminished considerably.

At this period the doses for the baths can be increased if the patches are disseminated, or the ointment if they are localised. For the baths chrysarobine may be added provided the kidneys are in good condition.

Oil of cade, 4 oz.
Yolk of eggs, No. 2.
Extract of quillaia, 5 drs.
Chrysarobine, 15 grs.

These baths are taken twice a week.

At this period Drew's ointment may also be applied, but only over small surfaces (a hand palm):—

Salicylic acid, 3 drs.
Chrysarobine, 5 drs.
Vegetable tar, 5 drs.
Green soap, 1 oz.
Vaseline, 1 oz.

The ointment is put on at night.

At this point the patient is in a good way to recovery; only isolated patches are found, some in the hair, some on the elbows, etc. The treatment necessarily changes; one bath a week is now sufficient, for baths have already lost a great deal of their utility. The local patches will be treated with traumaticine and chrysophanic acid contained in two separate bottles. The first is a solution of guttapercha and chloroform:—

Guttapercha, 1 dr.
Chloroform, 9 drs.

The second:—

Chrysophanic acid, 1 dr.
Ether, 9 drs.
(Inflammable.)

After removing as much as possible the squamæ or scales by dry rubbing with a towel, the place is washed with soap and dried, the chrysophanic solution is applied with a brush on the patch of psoriasis taking care not to exceed the limits of the lesion. This solution dries quickly, leaving a fine deposit of the acid; then the traumaticine is painted over the surface and a little beyond the limits of the patch, thus realising an occlusive dressing. At the end of two or three days the patient recommences the operation.

Where the patches are rather large the cadic collodion of Gaucher should be preferred.

Pure cade oil, 3 drs.
Collodion of acetone anhydrous, 5 drs.

In psoriasis of the scalp, chrysarobine cannot be employed on account of its irritating effects on the eyes; it also colours the hair yellow! For dark-haired persons, the ointment of Gaucher may be used or the yellow oxyde of mercury ointment (1-10) and washing the scalp now and again with oil of cade soap.

For children neither pyrogallic acid nor chrysarobine should be used on account of their toxicity; weak oil of cade ointment or naphthol alone are advisable.

Such is the treatment, concludes Prof. Gougerot, of psoriasis, which can at the same time serve as a type for the treatment of all skin affections, which, like psoriasis, are squamous and non-irritable.

AUSTRIA.

Vienna, Jan. 3rd, 1914.

AT the recent meeting of the K.k. Gesellschaft in Vienna, Dr. R. O. Stein (Professor Finger's clinic) exhibited four patients affected with

LEPROSY,

and demonstrated the various lesions and symptoms presented by each. Two of them were brothers, from Vukujevac (Servia). Their father died some months ago, and had apparently suffered from a mutilating form of leprosy. They presented the characteristic stigmata of leprosy in their features—eyebrows and eyelashes had disappeared, the outlines of the nose were expanded beyond the normal, the cartilaginous septum had sunken, the naso-labial folds were shallow. The following details were noted:—

Nose.—Defect of cartilaginous framework of nasal skeleton, with striking deformity of external contour of the nose. Atrophy of alar cartilages, and consecutive stenosis of vestibulum nasi. Behind the highly stenosed opening of the nostril blood concretions were visible. Posterior rhinoscopy showed contraction of the choanæ; these were oval and symmetrical. A flat area of loss of substance of the mucous membrane of the soft palate and uvula, of about the dimensions of a bean, was present; and similar superficial ulcerations, which had healed over, were traceable in various other places, especially on the right wall of the pharynx and the posterior portions of the alveolar arches. The tonsils were completely shrivelled. The epiglottis was omega-shaped, puffy and displayed, on its lingual aspect, three knobby masses of infiltration, of the size of small peas, projecting under the mucous membrane. The plica pharyngo-epiglottica and larynx were free.

Eyes.—Interstitial keratitis of the right eye, and chronic irido-cyclitis of both eyes.

The skin of the trunk and of the extremities is covered with an exanthem that consists of yellowish-brown spots with vaguely-defined margins, which, in many cases, were very slightly elevated in the centre; these fused together so as to form larger and smaller polycyclic diffuse patches, of brownish tint, leaving some areas of normal skin between. The central elevation is produced by closely juxtaposed groups of lichenoid papulæ. At first sight the cutaneous affection reminds one by its tint of pityriasis versicolor; but it is distinguished from the latter by the absence of branny scales, and by the presence of a conspicuous, stellate, wholly superficial atrophy (dermatitis atrophicans leprosa of Oppenheim).

The hands and feet are ætroasphyctic. The small muscles of the hand are atrophic on both sides. On the lower extremities are seen brown lichenoid patches on the inner aspect, some isolated and some running together to form knotty knobs of infiltration of larger or smaller dimensions, bearing scales or crusts on their surfaces. The feet are œdematous, violet-blue in colour; and on the inner border of the left foot are two irregularly-shaped, indolent ulcers, each of about the dimensions of a heller.

Testing the cutaneous sensibility demonstrated the existence, on both upper and lower extremities, of patches of which some were wholly anæsthetic; and others dissociated only as regarded perception of temperature and pain, but were not anæsthetic to tactile stimuli. This condition recalls that found in syringomyelia.

The other two patients were females, of Spanish origin, but usually resident in Constantinople. One is the daughter of a leper; the source of infection in the other case is unknown.

Dr. F. Schlemmer dealt in further detail with the rhinoscopic condition, and demonstrated the episcopic illustrations which had been prepared by Hr. Wenzl. These show the condition of the gums and pharynx, with their diffuse patches of infiltration and knotty formations. The mucous membrane displayed its yellowish-red, in many places yellowish-white, surface, from which flattened papules, or approximately spherical knobs, projected: of bright rose, whitish, or dull yellowish tint—sometimes surrounded by a mother-of-pearl-like border. The infiltrates and knobs are anæsthetic; the dry mucous membrane is glossy.

Dr. L. Freund discussed the treatment. Large torpid ulcers on the dorsum of each foot, which were of old standing, were rapidly cured by dosage with weak Röntgen rays. We can hardly describe this effect correctly as healing of leprous ulceration, the latter process not being due to the lepra bacillus; but it will be understood that on the anæsthetic patches lesions are likely to occur, and are readily overlooked; as a result of which the affected part becomes a seat of infection, and ulceration is a secondary process. The all-important matter for the patient is to have such ulcers skilfuly treated by radio-therapeutic methods, as they frequently lead to mutilation.

Dr. W. Stiassny pointed out that good results had been obtained from diathermy in the treatment of leprosy. This procedure has the great advantage over hot-air and direct heating applications of influencing the deep tissues and organs.

MR. GWYNNE WILLIAMS, M.S.Lond., F.R.C.S.Eng., has been appointed Surgeon to Out-patients at the Great Northern Central Hospital.

UNITED STATES OF AMERICA.

New York, Dec. 1st, 1913.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA (*concluded*).

DR. FREDERICK R. GREEN, of Chicago, spoke on education and publicity with reference to

THE CAMPAIGN AGAINST CANCER

by means of the Council on Health and Public Instruction of the American Medical Association, and said in part that the real force in the United States, and the only effective force was public opinion. In guiding public opinion with respect to the need for a campaign against cancer, and in demonstrating the efficiency of measures to fight the evil the Council on Health and Public Instruction could obviously do much, representing as it did the organised profession of the entire country. By means of its machinery, it could, without any additional expense, place before the public any information which might be desired on the question.

Mr. Frederick L. Hoffman, of Newark, N. J., read a paper on the

EDUCATIONAL VALUE OF CANCER STATISTICS

to insurance companies, the public and the medical profession. Mr. Hoffman brought out some valuable information gathered from statistics in relation to cancer. He stated that during the year 1910, the average age at death in cancer and other malignant tumours combined was 59.2 years for the registration area of the United States. For males the average age at death was 60.4 years, and for females 58.4 years. Considered by organs or parts affected, the average age at death in cancer of the buccal cavity was 63.1 years; in cancer of the stomach and liver 61.2 years; in cancer of the female generative organs, 53.8 years; in cancer of the breast 58.3 years; in cancer of the skin, 68 years; and in cancer of other organs and parts not specified, 56.9 years. Cancer was distinctly a disease of advanced adult life. During the decade ending with 1911 the cancer death rate for all ages had increased from 65.8 per 100,000 of population in 1901 to 83.9 in 1911. Cancer in the experience of the insurance companies had been the subject of occasional consideration, but not of very extended and thorough specialised inquiry. A review, however, of the available statistics, extending over more than a century, tended to confirm the conclusion that during the long intervening period of time the mortality from cancer had gradually and persistently increased from a comparatively low rate of frequency to proportions which might appropriately be considered a menace to civilisation. On Friday, November 14th, Sir W. Arbuthnot Lane made some further observations on

CHRONIC INTESTINAL STASIS

and laid emphasis upon the fact that by operative measures he had cured a very large number of cases of a serious nature which had accompanied obstinate chronic intestinal stasis

Dr. Roswell Park, of Buffalo, read a paper on the relation of the ductless glands to the work of the surgeon, and drew attention to the ever growing recognition by physicians and surgeons of the influence exerted by the internal secretions upon the organs and functions of the body. He said in part, that the internal secretions, so often spoken of as hormones, exercised an apparently controlling influence on many of the organs and functions, and this not only on the ordinary body functions, but on the nutrition and regulation of individual organs and their particular activities even to the extent of becoming responsible for the development of certain mental traits or personal characteristics which might make or mar the individual and might thus affect both his physical and intellectual welfare. Dr. Park gave several examples of such occurrences and described the surgeon's *rôle* when called upon to treat abnormalities brought about by the inactivity or excessive activity of the ductless glands.

Papers of much interest were also read by Dr. Chas. Mayo, of Rochester. Min, who summed up the goitre question; by Dr. John P. Binnie, of Kansas City, who dealt with some uses of fat in surgery; Dr. V. P. Blair, of St. Louis, discussed peridental infections and their relation to neighbouring organs; Dr. G. Hudson Makuen, of Philadelphia, considered the surgery of the faucial tonsil as it relates to the functions of the tongue and soft palate in the production of voice, and Dr. Edward Jackson, of Denver, Col., discussed operations on the extra-ocular muscles.

The following officers were elected: President, Dr. John B. Murphy, Chicago; Vice-president, Dr. George E. Armstrong, Montreal; Secretary, Dr. Franklin H. Martin, Chicago. It was decided to hold the next meeting in London, Ontario, during the last week of July, 1914.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

ROYAL INFIRMARY, EDINBURGH.

THE annual report of the Infirmary, to be submitted to the meeting of contributors on January 3rd, has just been issued, and is of especial interest in its bearing on the Insurance Act. The report states that notwithstanding the Act, the Infirmary is as great a necessity as ever. During the year 12,514 in-patients were treated, 4,096 being medical and 7,588 surgical, the average number in residence being 858, and the average period of stay in hospital 22.4 days for medical and 21.1 days for surgical cases. The percentage of deaths was 6.9, or, excluding deaths within 48 hours of admission 4.8. The ordinary income was £36,033, an increase of £641, and the ordinary expenditure £56,609, an increase of £727—a cost per occupied bed of £65 19s. 7d., being 3s. 11d. more than last year. Legacies and donations brought in £43,984, and the extraordinary expenditure was only £1,143. The report describes the new agreement as to clinical teaching as likely to benefit both the medical school and the infirmary, and states that care has been taken to safeguard the right of the managers to control the whole internal arrangements of the infirmary as hitherto. Statistics of the insured persons treated have been kept, and show that for the 11 months to December 14th, 1913, 43.67 per cent. of the in-patients and 32.46 per cent. of the out-patients were such. In other words, 44 per cent. of the whole expenditure of the institution was incurred in dealing with insured persons. For this reason the managers consider that they have a strong claim for substantial support from the Burgh Insurance Committee and Approved Societies. In view of this a conference was held with their representatives in December, when an appeal was made that they should exercise the powers granted by Section 21 of the Act. In order to preserve the "open door" principle of the hospital the managers decided more than a year ago that no claims should be made for any of the sickness benefit of insured persons having no dependants who might be treated in hospital, and consequently no agreements have been entered into with any of the Approved Societies.

TEETH OF WEST LOTHIAN SCHOOL CHILDREN.

In his annual report on the school children of West Lothian, Dr. John Hunter speaks very strongly, both as to the amount of dental cases, and as to the absolute indifference shown by the parents when their attention is drawn to it. Most of them think it is hereditary—they themselves have bad teeth, and their children also must suffer. Of 1,586 girls examined only 358 had satisfactory teeth, and the same proportion was found in boys. "Satisfactory" means only that there was no actual caries, but does not mean that the teeth were complete. The lack of interest taken as to cleanliness and preservation of teeth is all the more regrettable when it is stated that half of the children leaving school, and suffering from dental caries, were yet in such a condition that their teeth could be saved at very little expense.

Conservative dentistry, however, is unknown among the children.

CRIME IN SCOTLAND.

The statistics of crime in Scotland for the year 1912 are now available, and the leading feature is, on the whole, an increase—most marked in assaults, theft, housebreaking, indecency, breach of the peace, and drunkenness. There is a noticeably large number of persons committed to prison in default of payment of fines—36,631 out of 89,013. Thus 41 per cent. of those sentenced to pay fines go to prison instead, but of these, 11 per cent. pay part fines after admission. In England only 14 per cent. of those sentenced to fines go to prison in default. This appears to indicate that the fines imposed in Scotland are excessive, and out of proportion to the means of the person fined. The Commissioners believe that were greater care taken to assess fines the number imprisoned would diminish. Six females and 97 males were sentenced to Borstal treatment, but there is a large decline in those sentenced to preventive detention—only 7, as compared with 21 and 41 in the two years preceding. The Probation of Offenders Act, 1907, was enforced in only 3,730 instances, which is satisfactory in so far as it shows an increase, but still leaves much to be desired. Since a properly worked probation system sensibly reduces the need for sentences of imprisonment, it is desirable that inquiry should be made into the administration of the Act in Scotland. The total number of persons dealt with in the criminal courts has increased by 4·77, or 7,349 cases. The rise under the head of drunkenness and breaches of the peace accounts for three-fifths of this number. Serious crimes against the person—assault, cruelty to children, etc.—have risen by 9 per cent.; theft with violence, including housebreaking, by 13 per cent.; theft without violence has also gone up 12 per cent., though many of the offences were trivial. Sentences of penal servitude are fewer, but those to the longer terms (4 and 5 years) are relatively more numerous, indicating a tendency to inflict severer sentences as a deterrent. Juvenile offenders have increased by about 600. Seven males and 27 females were received into certified inebriate reformatories, and 19 males and 7 females into the criminal lunatic department at Perth.

SCOTTISH INSURANCE COMMITTEES.

The subject of dispensing by doctors was before several of the Scottish Insurance Committees on the 27th ult. At Duns, Berwickshire, a letter was read from one of the panel practitioners stating his desire to continue dispensing on the capitation basis. The Chairman said this was not a case where there was no chemist and where the doctor dispensed for everyone. Under the new regulations they could not grant the application referred to, to continue dispensing generally on the capitation basis. They would have to ask the doctor to furnish a list of patients residing over a mile from the nearest chemist's, and to state the reason why he should dispense for them. It was agreed to do this. A new form of agreement with the doctors for the county has been drawn up and signed by six out of the panel of thirty. In the clause which says a practitioner shall not accept any fee or remuneration for any treatment required to be given under the agreement the doctors suggest the substitution of "shall not charge," to which the Commissioners would not agree. At Wick a letter was read from the County Pharmacists' Association, protesting against doctors who dispense medicines in rural districts being paid by capitation instead of at the tariff rates. After hearing Mr. Cumming, a representative of the chemists, the Committee also heard Dr. Kennedy, Dunbeath, who said that Mr. Lloyd George intended that doctors in rural districts who did not get the same benefits as those in urban areas should receive the capitation grant. With only one dissentient, the Committee decided to continue payment to the doctors on the capitation basis.

Glasgow Insurance Committee has issued the panel list for the medical year, which commences on January 12th. Out of about 500 practitioners in the city, 382 are on the list, with 192 chemists. The number of insured persons within the area is now about 385,000, which gives an average list of about 1,000 insured persons per doctor, so that there is provided an adequate medical service. To all those persons who have already made a choice of a doctor a new form of medical card will be issued by the Insurance Committee, in substitution for the medical ticket at present in use, while a form will also be issued to all those persons who have made application to change their doctor as at the close of the medical year. Other persons who have not up to the present made a choice of a doctor will only be able to do so after January 11th on making special application to the Insurance Committee for a medical card.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE QUESTION OF REFORM OF THE B.M.A.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—"An Obscure Practitioner" asks me whether I believe that the apathy of members of the Association will be overcome by raising the subscription. My answer is in the affirmative, because such a step will increase the efficiency of the Association. Many members are clamouring for the Association to undertake this and that duty, and because it cannot, on account of its strained finances, such men are in the first place disappointed, and then become apathetic. If we demand increased work of the Association we must pay for the increased expenditure. I disagree entirely with "An Obscure Practitioner" when he writes: "Not as many as 5 per cent. of the scientific papers and lectures of any kind deserve full or verbatim report." I wonder whether your correspondent has ever tried to cut down a scientific paper? If so, I am sure that he appreciates the difficulty of the task. Here again we have the personal element: I prefer a full report, your correspondent an abridged one.

Again, your correspondent refers to "Nova et Vetera," a contribution which I always read with the greatest interest and profit. Your correspondent has no interest in these links with the past. Again, with regard to the reviews. Surely if you are contemplating the purchase of a new book it is more satisfactory to be able to refer to a lengthy review, in which its virtues and shortcomings are carefully noted, rather than to have some brief notice from which you can glean anything or nothing.

The epitome of literature is of the greatest possible value to the busy practitioner who is endeavouring to keep up to date. Let "An Obscure Practitioner" take twenty colleagues at random, and inform these gentlemen that the *B.M.J.* is to be cut down by one quarter, and request each of these gentlemen to suggest how this can best be done. I guarantee that if the advice given were acted upon, the *B.M.J.* would cease to exist. Let us not starve the Association and affect astonishment at the result. Let us not blame the Association for our own shortcomings. Let us not dilate upon what should be done in our opinion, in a general way, but rather concentrate our attention upon *how* it should be done, and produce a practical and practicable scheme.

It is all very well to suggest the halving of the sum paid to editorial contributors. I dare say that there are many men who would do the work for a quarter the sum paid. The question is: How would it be done? If the *Journal* suffered in prestige, the loss to the Association would be incalculable.

I am, Sir, yours truly,

"Monkhams," Bedford. S. J. ROSS.

December 31st, 1913.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Personally, as an old member of the British Medical Association, I am extremely glad to find that the matter can be discussed in columns that are in no sense unfriendly. Dr. Ross is so enthusiastic in his

friendship that he can see nothing wrong in its administration. Surely it would be wiser to admit faults and errors with a view to putting them right. One main fact cannot be gainsaid, namely, that the present Executive has brought the Association to the brink of financial ruin. I trust that some of your correspondents will deal with what appears to me your eminently sane editorial suggestion that the affairs of the Association be submitted to expert Actuarial report with a view to sweeping administrative reform.

I am, Sir, yours truly,
20 YEARS A MEMBER.

Bristol.
January 2nd, 1914.

THE SELECT COMMITTEE ON PATENT MEDICINES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Judging from various recent utterances in your paper, there have arisen serious misapprehensions as to the constitution and references of the above-named Committee which it is desirable should be cleared up. The Committee was appointed "to consider and inquire into the question of the sale of patent and proprietary medicines, and medical preparations and appliances, and advertisements relating thereto; and to report what amendments (if any) in the law are necessary or desirable." The Committee began its sittings in 1912, and stands now adjourned until next Session.

The Committee has strictly confined itself within the limits of its instructions. It had no authority, and it has assumed none, in the question of practice by unqualified pretenders, although the sale of patent medicines and bogus apparatus forms the cloak for a vast amount of fraudulent quackery. The Committee has gathered a great mass of evidence. This is all in type. It will doubtless be published with the report, and this, we may hope, will be out by the end of the forthcoming Session. The trades under inquiry are producing an annual income of more than £4,000,000, and of this at least £1,500,000 is spent in newspaper advertisements. It is not, therefore, surprising that attempts should have been made to obscure the issues, or to throw dust in the eyes of the Committee. That these attempts will succeed need not be feared, since the Committee is made up of men of the world, including medical men and leading journalists More than enough unimpeachable evidence has been accumulated to prove that the traffics in question are, to a vast extent, grossly fraudulent; that they are seriously injurious to the public health; that they are the cause of much unnecessary suffering and of a considerable easily preventable mortality. The evidence will, I believe, make clear the fact that newspapers which derive great incomes from quack advertisements are fully aware of the nefarious character of the trade which flourishes by their help. The evidence will show that although there are of course many exceptions, the majority of leading papers are involved in this great scandal, and that their conduct forms the justification for the mass of inferior papers which, whilst setting themselves up as the protectors of the poor, fill their pages with lying puffs, to the detriment of their ignorant and suffering readers.

It is understood that the Committee, in accordance with its specified powers, has set the Government analysts to work upon an examination of typical patent medicines. This cannot fail to add support to the strong evidence already tendered. Whatever the recommendations of the Committee may be, there can be no doubt that their proceedings will furnish material extremely valuable in the promotion of a wide scheme of medical law reform, and we must now wait patiently for the issue of the Report.

I am, Sir, yours truly,
HENRY SEWILL.

The Old Rosery, Earlswood Common
January 1st, 1914.

[Time alone will show whether the Royal Commission will have the desirable results anticipated by our correspondent, who is entitled to speak with some authority on the point, or whether it will fulfil the confident prediction of certain politicians that it was never intended to attain full fruition.—ED. M.P. and C.]

THE PRIVY COUNCIL, THE APOTHECARIES' HALL, IRELAND, AND THE GENERAL MEDICAL COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You have duly recorded that the General Medical Council decided to send "for the information of their Lordships" of the Privy Council, certain charges and allegations against the Apothecaries' Hall of Ireland. Of course, the General Medical Council voted on this matter without the advice of its Legal Assessor.

I took the liberty of protesting publicly against the action of the General Medical Council as absolutely unconstitutional. The Medical Acts state "it shall be lawful" to address a complaint to the Privy Council against a licensing body, but only when duly appointed inspectors, after due inquiry, have declared its examinations "insufficient" Anybody with the most rudimentary knowledge of law knows that when a certain procedure is laid down by Statute, previous to approaching the Privy Council, that body will not consider statements made in any other fashion.

What has happened? The inevitable, of course. The Privy Council has given the General Medical Council the greatest snub ever administered to a body entrusted with important medical functions. After having received the elaborate dossier of charges and allegations, the Privy Council refuse to look at it. Metaphorically, they throw it into the wastepaper basket. Frigidly ignoring the General Medical Council, they state, in cold official formula, that "the matter is not before them."

I cannot but think that the distinguished Legal Adviser to theGeneral Medical Council is aghast at the awful impropriety of their action in attempting to influence the judgment of their Lordships of the Privy Council. That body is the Court of Appeal set up by Parliament, and the judgments of the lower court, that of the General Medical Council, must come regularly before it for revision, rejection, or approval, but it cannot tolerate any attempt to defeat its judgment in a case which is not before it, and which the lower court has not decided.

Somehow, the Irish Apothecaries Hall seems to have got on the nerves of the General Medical Council, and the net result does not augment the dignity of that body. They trust to wipe us off the earth by reporting us to the Privy Council, and that body decided in favour of the Hall, which is now one of the only five licensing corporations in the British Empire which can give a complete qualification. They next tried to ruin us by making us pay fees for surgical examiners from London and Edinburgh—men of the standing of the President of the English College of Surgeons. We had to pay up, of course, but we have got about forty distinctly favourable reports on our examinations from the highest authorities—a series of favourable reports not only greater than any other corporation or university can show, but probably almost equal to the number of favourable reports which all the universities can exhibit.

When we asked the Council patiently, year after year, to allow us to hold a preliminary examination under the Fellows of Trinity, they simply sneered and refused. Now we have demonstrated, and they no longer attempt to deny, that we can hold a preliminary examination when we choose. We have also been compelled to prove, in making our case, that there is no legal warrant for the Students' Register, and that the reconstruction of any preliminary examination by the General Medical Council really means nothing except that they like it. We have shown also that their appointment of inspectors to the examinations of the Hall has been irregular, and probably illegal, and that the payment to them should be surcharged.

One would have thought that the General Medical Council would certainly not take another step against

the Hall without their Legal Adviser's instruction. Not at all. A resolution to take that official's advice on the appointment of Dr. Finny and Mr. Maunsell was defeated.

Anyone who takes the trouble to look at Smith's "Law for Medical Men" will see that only the General Council, and not a Branch Council or the President, can appoint "inspectors" under the Act of 1886. When an examiner is appointed under that Act his duty is to "maintain the requisite standard," not to report on it. Sir John Moore stated in the Council, possibly correctly, that Dr. Finny was appointed under the Act of 1858, which dealt not with the qualifying, but with the intermediate examinations. Now the 1858 Medical Act only dealt with courses of study and examinations—mere matters of curriculum. Under that Act the General Medical Council could report a body to the Privy Council if it did not require evidence of study and examination, say, in operative surgery, fevers, ophthalmology, vaccination, or the like. But a licensing body might require evidence of study, and actually examine in these subjects, and yet have too low a standard of proficiency in qualifying subjects. To remedy this the amending Act of 1886 was brought in, to enable the Council to appoint inspectors who shall report on the "qualifying" examinations. Now a "qualifying" examination is defined as an examination in medicine, surgery and midwifery. Up to the present it had been the custom to appoint the surgical examiners (A.H.I.) as inspectors, and they were thus entitled to report on the sufficiency of the examinations, but now Dr. Finny, appointed under the Act of 1858, is present at the medicine and midwifery part of the final, whilst the surgical examiners may report, not as inspectors, but as examiners, in the surgery part.

In other words, there are now no inspectors to the examinations of the Irish Apothecaries' Hall whose reports could be sent to the Privy Council, or, if they were sent, the Privy Council would reply that "the matter was not before them."

I am, Sir, yours truly,

J. C. McWalter, M.D., LL.B., F.R.F.P. and S. Dublin.

POLYARTICULAR RHEUMATISM TREATED BY PHYLACOGEN.

To the Editor of The Medical Press and Circular

Sir,—I have read Dr. Judd's paper which appeared in the Medical Press and Circular of December 31st, 1913, with much interest. It would be well if other practitioners would send notes of cases treated by remedies still *sub judice*.

The case he reports has many features of interest. To begin with, there is the history of pneumonia, and I have personally no doubt that it was an important ætiological factor, since I hold very strongly that all germs linger in the human system indefinitely, and may be contributory factors in the production of such ailments as so-called rheumatoid arthritis. Dr. Judd wisely labels his case arthritis without the prefix rheumatoid. Here we have a patient who was suffered many years, and by the majority of medical men would, I am sure, be labelled incurable and no doubt the joints considered ankylosed. It is not sufficiently widely known that the joints are often comparatively movable in arthritis, but are kept rigid by chronic spasm of muscles.

It should also be noted that the treatment was directed to the general condition, and not specially to the joints. I am glad to note that Dr. Judd sides with those who regard these troubles as infective. That toxins generated by imperfect digestion of foods may contribute I do not deny; so may alcohol, lead, nicotine, arsenic, or any other poison, but germs must always, in my opinion, be strongly borne in mind.

He made his injections in various regions: this is of value. He went on day after day pushing up his doses and set up a sharp reaction. As a rule, anything of the nature of a vaccine is given with considerable intervals between the doses.

He succeeded in doing his patient a great deal of good, therefore his *technique* was apparently correct.

Sir Clifford Allbutt warns us against rousing storms we cannot quell.

Sir Malcolm Morris says we must not be too afraid of setting up a reaction. You pay your money and take your choice. Dr. Judd chose the bold course, and I take off my hat to him. I daily set up reactions myself by means of various irritants, and I regard the process as highly beneficent, but so far nobody has yet given me a good explanation of what reaction really is. I should be grateful if any one of your readers will do so. Surgeons will dare anything, but physicians are a timid class, and so thousands of patients are allowed to go on, a burden to themselves and others, who might be cured by taking a few risks. I hope Dr. Judd will publish notes of some of the subacute cases he has treated.

I am, Sir, yours truly,

W. J. Midelton.

Bournemouth.
January 2nd, 1914.

OBITUARY.

THE LATE PROF. GILSON, OF EDINBURGH.

Many old Edinburgh men will learn with regret the death in his 59th year of Professor John Gilson, Ph.D., which took place at his residence near Edinburgh on New Year's Day. Professor Gilson was born in the city, and educated at the Edinburgh Academy. He studied chemistry in Heidelberg under Bunsen, and in 1879 was appointed assistant to Professor Owen Brown, a post which he held until 1892, during the whole of which period he was associated with the medical school. In 1892 he was promoted to the Professorship of Chemistry at the Heriot-Watt College, and successfully conducted, up to the time of his death, this large and important department of teaching and research. His published papers were numerous, and included researches on the "manganese nodules" for the *Challenger* expedition, on the rare earths, especially beryllium, and in his later years on physical chemistry, particularly the electrical conductivity of saline solutions. Just before his death he had successfuly brought to a conclusion the important task of designing new laboratories for the Heriot-Watt College. Dr. Gilson was a highly cultivated man outside of his own subject, and was for some time President of the Goethe Society.

DR. JOHN GORMAN, OF BANGOR, CO. DOWN.

We regret to announce the death of Dr. John Gorman, L.R.C.P. and S.Edin., F.R.P.S.Glasg., of Bangor, Co. Down, which occurred with tragic suddenness on December 27th. Dr. Gorman was at work as usual on the day of his death, but had been feeling run down for some days. After his morning's work on the day of his death he went to lie down, feeling somewhat fatigued, giving directions that he was to be called a couple of hours later. A member of his household went to call him, and, receiving no answer, went into his room to find that he had passed away, apparently in his sleep. Dr. Gorman was only 46 years of age. He studied medicine at Queen's College, Belfast, and in Dublin, and obtained his qualifications in Edinburgh in 1894. He also held the diplomas of the Pharmaceutical Society of Ireland. After qualifying in medicine, he acted as assistant to Dr. Forsythe, of Manchester, for eighteen months, after which he returned to Ireland and commenced practice in Bangor, where he has been for the past eighteen years. Dr. Gorman was at the time of his death honorary surgeon to the Cripples' Home, Bangor, and gave unstintingly of his services to that institution. He was also one of the medical officers to the Bangor Hospital, in which he did a good deal of sound surgical work. Dr. Gorman was a good all round practitioner and was a universal favourite with his patients and colleagues. His loss will be keenly felt in Bangor and the surrounding districts in which he had established an extensive practice. Great sympathy will be felt for his widow and two children in their bereavement.

LITERARY NOTES.

UNDER the title of "Dr. Boucard's Lacteal Memoranda" a well-bound red engagement list is issued for the use of medical practitioners. There is a page for each day of the week throughout the year, with a note of fees paid and owing, and a sheet at the end of each month for a debit and credit summary of individual patients, and an index at the end. This is a handy little book of the kind for anyone in want of that kind of thing. A copy of "Lacteal Memoranda" will be sent free to any medical man who writes for it to M. Bresillon and Co., Gamage Buildings, Holborn, London, E.C.

* * *

Messrs. Hanna and Neall, Dublin, send us "A Calendar of Anniversaries of Dr. Steevens' Hospital," compiled by Dr. T. P. C. Kirkpatrick. The compiler, from his researches among the hospital records, has selected one event of interest for each day of the year. The result is an interesting and amusing medley, as some of the events mentioned are historic events of importance, others relate to the appointments of various members of the staff, and others—and these perhaps the most interesting—have to do with domestic occurrences. We learn that in 1769 the attendant at the hospital ferry-boat was so remiss in his duties that a letter of complaint appeared in the *Freeman's Journal*. As recently as 1872 the nurses in the constabulary ward were reported for selling drink to the patients. In 1849 a nurse was restored to her place, "she having taken the pledge." Three years earlier "Mr. Stoney, resident pupil, was dismissed the hospital for annoying the apothecary." The "Calendar" will prove, as Dr. Kirkpatrick says, a pleasant memento to old Steevens' men the world over.

MEDICAL NEWS IN BRIEF.

Death from Anthrax.

AN inquest was held at Oxford last week on the body of Joseph Brookings, aged 41, a wool mixer, living at Witney, who died at the infirmary from blood poisoning following anthrax. Dr. T. M. Legge, one of his Majesty's Medical Inspectors of Factories, was present.

The widow stated that her husband had been a wool mixer employed by Messrs. Thomas Carr and Co., yarn spinners, of Dewsbury. He went to Witney to spend Christmas, and she noticed that he had a small pimple on his neck and two or three days afterwards it assumed the appearance of a boil. A doctor advised his removal to the infirmary, where it was found that he was suffering from anthrax.

In reply to Dr. Legge, the witness said there had been two previous cases of anthrax in the factory, one about a year ago and the other 12 months before that. The second was that of a wool mixer. In both cases the men were working on imported wool. There was an apparatus at the mills for drawing away the dust and fibre. It was the duty of the deceased in turn to clean out the dust chambers. Respirators were used in the mill. The raw material was English cowhair, English wool, and English waste. The latter the witness thought came from Huddersfield. Brookings did not work in, nor did he go through, the room in which the imported wool was being handled.

William Keats, wool mixer, employed at the mill and working with Brookings, in answer to Dr. Legge, said there was not much dust in the work on which they were engaged because of the fanning apparatus which removed it. He had never seen the warning placard which had been produced, but he had heard men in the mill speak of anthrax. He had cleaned out the dust chamber but did not wear a respirator, nor had he ever seen one until the previous day. He had not seen regulations posted in the factory, but he could not swear there were not any.

Dr. Legge said that the number of cases of anthrax had been increasing of late years, especially in the class of factory in which Brookings worked. As a result the Secretary of State thought perhaps the regulations were not sufficient to cope with the disease, and had appointed a committee to inquire into the danger of infection with a view to seeing if something more could be done to minimise the risk.

The medical evidence showed that death was due to blood poisoning as the result of anthrax, and a verdict to that effect was returned.

The Royal Institute of Public Health.

It is announced that the twenty-third annual congress of the Royal Institute of Public Health will be held in Edinburgh in July, 1914, upon the invitation of the Lord Provost and the city council. The meetings will take place in the University of Edinburgh under the presidency of the Marquis of Linlithgow.

The congress will be conducted in the following sections:—(1) State medicine, sub-sections (*a*) epidemiology; (*b*) urban, rural, and port sanitary administration; (2) bacteriology and comparative pathology; (3) the hygiene of infancy and school life; (4) industrial hygiene; (5) naval, military, and colonial hygiene; (6) tuberculosis.

The following have been appointed general honorary secretaries for the congress:—A. Corbett-Smith, M.A. Oxon., London; J. Hally Meikle, M.A., M.D., School Board Offices, Edinburgh; W. H. Meikle, M.A., LL.B., 14, Hill Street, Edinburgh; John L. Somerville, C.A., 59, George Street, Edinburgh.

Free Lectures at the Queen's Hospital for Children, Hackney.

We are asked to announce that a course of clinical lectures and demonstrations will be given by members of the medical and surgical staff at the above hospital during January, February and March. These lectures will be free to all medical practitioners and students of medicine and will be delivered in the board room of the hospital in the afternoon, at 4 o'clock, on the following dates:—January 6th, 14th, 22nd and 28th, February 3rd, 12th, 18th and 26th, March 6th, 10th, 20th, 23rd and 30th. Further particulars may be obtained of Dr. E. Bellingham-Smith, Hon. Sec. of the Medical Committee.

£70,000 for Cancer Hospital, Brompton

A SUM that will amount to nearly £70,000 has been left to the Cancer Hospital, Fulham Road, under the will of Mr. Thomas Cuvelje, for 52 years a member of the London Stock Exchange, who died on November 25th last, aged 82 years. The estate of the testator is valued at £110,446 gross, with net personalty £110,100.

After bequeathing £5,000 each to the Surgical Aid Society and to the Royal Hospital for Incurables, Putney, £2,000 to the Stock Exchange Benevolent Fund, and legacies to his servants, as well as some private bequests, he left, as stated above, the residue of his property to the hospital.

A Case of "Spotted Fever" at Berwick.

AN inquest was held at Berwick last week concerning the death of John Haigh, a seaman from the steamer Glenbroke, at present lying at Budle Bay. Haigh took ill after leaving Newcastle, and was landed at Holy Island, whence he was conveyed to Berwick Infirmary, where he died. Death was certified to be due to cerebro-spinal meningitis or spotted fever. The Coroner remarked on the dangerous nature of the disease, and Dr. Fraser said every precaution had been taken. Dr. Heagerty, the medical officer, said Haigh's belongings had been burned and the ship disinfected and placed in quarantine.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3 and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

M.B.GLASG. (Inverness).—Periodical soreness of the tongue and gums was described by O. Schaumann about two years ago as being an early symptom of pernicious anæmia. Dr. Heinrich Stern ("Archives of Diagnosis") has recently described two cases in which this sign was present. Little is known as to its pathology.

DR. S. W. (Essex).—The issue of such a circular would certainly be regarded as "infamous conduct in a professional respect," and the sooner it is withdrawn the better.

POST-GRADUATE COURSE ON THE FEEDING AND CARE OF INFANTS.

IN view of the large number of applications for permission to attend separate lectures of the above Course, the National Association for the Prevention of Infant Mortality has decided to issue tickets at 1s. each for any single lectures that students may desire to attend. Prospectuses and tickets may be obtained from the Secretary at 4 Tavistock Square, W.C.

DR. K. T. (Herts).—Considering that one milligramme of mesothorium costs at present about £7 10s., it compares most favourably with radium. Recent observations show that mesothorium has a softer action than radium, and that it possesses many of the advantages of the ultra-violet rays and of carbonic acid snow.

DR. D. A. (London, S.E.).—It has been shown by Moritz and Detlen as a result of X-ray studies, that, while the normal heart becomes slightly smaller in severe exercise, the heart whose muscle is diseased or weakened undergoes great dilatation. It would be more prudent, therefore, to submit the patient to a careful medical examination before allowing him to compete in such a contest.

THE BOOK MARKET OF 1913.

WHETHER it is attributable to the general uncertainty and unrest that characterised the general trend of events throughout the past year, the falling off in the number of students who entered the medical schools, and the consequent lesser demand for medical literature, the fact remains that there were about seventy fewer works in medicine and surgery, published during 1913 than in 1912, and nearly as many fewer than in the previous year.

A YORKSHIRE READER.—The populations of the two cities referred to do not differ greatly; that of Leeds is given officially as 457,295, and that of Sheffield at 471,662. The former, although in the throes of a big municipal strike, appears to have been unaffected by its unswept street, the death-rate remaining normal, lower in fact than any other of the large manufacturing towns in the county.

THE SUPPLEMENT FOR IRELAND.—In consequence of the present being "Index Number," the ordinary supplement for Ireland is unavoidably held over until next week.

Meetings of the Societies, Lectures, &c.

THURSDAY, JANUARY 8TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m.: Specimens by Dr. W. S. A. Griffith, Dr. Drummond Maxwell, Dr. T. W. Eden. Short Communications by Dr. Drummond Maxwell, Mr. Hamilton Whiteford (introduced by Dr. Lockyer). Paper: Mr. Douglas G. Reid (introduced by Dr. Macnaughton-Jones): The Genito-mesenteric Fold of Peritoneum, its Relations and its Functions (with lantern demonstration).

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Address by Dr. Charles R. Box on "Pellagra" (with lantern demonstration).

THE NEW LONDON DERMATOLOGICAL SOCIETY (Western Skin Hospital, Hampstead Road, N.W.).—4.30 p.m.: Annual Meeting for election of officers. A discussion will be opened by Dr. G. Norman Meachen on "The Clinical Relationships of Lupus Erythematosus."

UNITED SERVICES MEDICAL SOCIETY (Royal Naval Medical College, Greenwich).—5 p.m.: Surgeon E. L. Atkinson, R.N.: Antarctic Experiences.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Board Room of the Great Northern Central Hospital, Holloway Road, N.).—9 p.m.: Paper: Dr. W. Hunter: Oral Sepsis in Relationship to Anæmia.

FRIDAY, JANUARY 9TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4 p.m.: Cases by Dr. Lambert Lack, Dr. W. H. Kelson, Mr. E. D. Davis, Mr. Norman Patterson, Dr. Andrew Wylie, Dr. E. A. Peters, and others.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Mr. Sidney Boyd, Dr. H. D. Rolleston, Mr. E. J. Boyd, Dr. Bernard Myers, Mr. W. Gordon Taylor, and others.

MONDAY, JANUARY 12TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on "The Pathology of Syphilis," to be introduced by Dr. W. d'Este Emery and followed by Mr Paul Fildes, Mr. J. E. R. McDonagh, Dr. J. McIntosh, and others.

TUESDAY, JANUARY 13TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY).—5.30 p.m.: Discussion on "Nephropexy and its Results," opened by Mr. G. Percival Mills, and continued by Mr. W. Billington, Mr. Leonard Gamgee, Mr. J. W. Thomson Walker, Mr. J. Sherren, and others.

Appointments.

BOYD, FRANCIS D., C.M.G., M.D.Edin., Chief Medical Officer to the Standard Life Assurance Company.

CROOM, D. HALLIDAY, M.D.Edin., Assistant Medical Officer to the Standard Life Assurance Company.

FRASER, Sir THOMAS R., M.D.Edin., Consulting Physician to the Standard Life Assurance Company.

HOOLE, JOHN, M.R.C.S., L.S.A., Medical Officer to the Rathbourne Convalescent Home, Parwich.

MARSHALL, COLE, M.D.Lond., F.R.C.S.Eng., Assistant Surgeon to the Western Ophthalmic Hospital.

MATHISON, G. C., M.D.Melb., Sub-Director of Clinical Laboratories at the Melbourne Hospital.

PATERSON, M. W., M.R.C.S., Medical Officer at the Central Branch of the Manchester Royal Infirmary.

Vacancies.

Hull and Sculcoates Dispensary.—Resident Surgeon. Salary £220 per annum, with extras. Applications to J. E. Stickney, Hon. Secretary. (See advt.)

Down District Lunatic Asylum.—Junior Male Assistant Medical Officer. Salary £170, rising to £200 per annum, with full extras, valued at £100 a year. Applications to Resident Medical Superintendent. (See advt.)

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Warminster (Wiltshire), Worthing (Sussex).

Joint Counties Asylum, Carmarthen, South Wales.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

County Asylum, Whittingham, Preston.—Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Nottingham General Dispensary.—Resident Surgeon. Salary £220 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

Wilts County Asylum, Devizes.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, attendance and laundry. Applications to Guy W. Jackson, Clerk to the Committee.

Births.

BACON.—On December 24th, at Hong Kong, the wife (*née* Charlotte Bailey, M.B.) of the Rev. J. L. Bacon, L.Th., of a son.

FAWKES.—On January 3rd, at Church Hill, Midhurst, Sussex, the wife of Marmaduke Fawkes, M.B., B.S.Lond., M.R.C.S., L.R.C.P., of a daughter.

WALLIS.—On January 3rd, at Carlton Road, Worksop, the wife of Dr. Ransome Wallis, of a daughter.

Marriages.

CANNEY—NEWTON.—On December 30th, at the Church of St. Mary the Great, Cambridge, James Robertson Campbell Canney, M.A., M.D., B.C.Cantab., elder son of Charles Richard Canney, of Cambridge, to Violet, elder daughter of Arthur William Newton, H.M. Inspector of Schools, of Bowman's Lodge, Cambridge.

HAIG BROWN—HENSLEY.—On January 1st, at Melton Mowbray, Clarence William Haig Brown, M.D., of Charterhouse, Godalming, to Agnes Beatrice, widow of F. F. Hensley, P.W.D., India, and daughter of the late John King, Field Place, Compton, near Guildford.

HOOKER—LLOYD.—On December 27th, at British Episcopal Church, Foochow, China, Alfred Wyatt Hooker, M.B., B.S.Lond., of the Wesleyan Missionary Society, Canton, to Maud Mary, only daughter of the Rev. and Mrs. Llewellyn Lloyd, C.M.S., Foochow, China.

MILLER—PRICE.—On December 30th, at Hendon, Dr. A. Ingram Miller, Stourbridge, to Dorothy, adopted daughter of R. Price, Esq., Bristol.

Deaths.

ALEXANDER.—On December 30th, at Blackwall Lodge, Halifax, Alicia Mary, the dearly-beloved wife of Reginald G. Alexander, M.D., J.P.

BRICE.—On December 15th, at 108 Festing Grove, Southsea, Frederick A. Brice, M.D., Fleet Surgeon, R.N., aged 49. Eldest son of the late F. A. Brice, M.D., R.N., Deputy Inspector-General of Hospitals and Fleets, of Croft Lodge, Paignton, and "Keltside," Dartmouth, and grandson of the late Lieut. W. H. Goddard, R.N.

HALL.—On January 3rd, 1914, at Bankside, Mayfield, Sussex, very suddenly, Henry John Hall, M.R.C.S.Eng., L.R.C.P. Lond., the second surviving son of the late Henry Acton Hall, of East Hanney, Berks.

SMITHIES.—On December 30th, at Clitheroe, Joseph Jackson Smithies, J.P., L.F.P.S.Glasg., L.R.C.P.Edin, aged 71.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, JANUARY 14, 1914. No. 2.

NOTES AND COMMENTS.

The Radio-active Water of Bath.

WHY go to the Continent for spa treatment when we have unrivalled springs within the four corners of our own dight little islands? Among our spas that of Bath enjoys the proud distinction of being the only one in Great Britain that possesses natural hot mineral springs of her own. Half a million gallons of water rise from the earth daily at a temperature of 120 deg. Fahrenheit, and are utilised for the medical treatment of a number of maladies, notably, of course, those of a gouty and rheumatic nature, or of the many allied arthritic affections which it is often not an easy matter to classify. The healing virtues of these waters were recognised long ago by the Romans, who built large and stately baths here during the first century, probably on the site of earlier British structures of a similar kind. The Roman belief in the much belauded waters of their Aquæ Solis—as the city was then named—has been more than vindicated by the researches of twentieth-century medical science. Sir William Ramsay has shown that these springs are the richest in the kingdom as regards radium, and that which represents the still more potent product of that wonderful element—to wit, niton—or the emanation of radium. So that the Romans had by sheer, downright, and, so to speak, rule of thumb observation, anticipated the findings of our latter-day science. Men may come and men may go, but the Bath springs remain the same—beneficent, healing, and—big Englanders take note!—of British birth and habitation.

A Restful Haven of Health.

THE bathing establishments of the Bath of 1914 are up-to-date and extensive. Under the courteous guidance of the Director of the Grand Pump Room—Mr. John Hatton—the present writer recently made a tour of inspection of the whole baths. Every kind of modern bathing appliance is to be found, including hot mineral water baths, hot air treatment, that most efficient method the Aix douche massage, vapour, Plombières, Nauheim, mud, oxygen, electric, brine, and a host of other baths. With all this wealth of healing waters close at hand it seems sheer ingratitude to send patients to some Continental spa for what they could procure just as well, or better, at home. Every class of patient is catered for at home—the wealthy in first-class hotels, the less wealthy in apartments, and the poor in the famous Mineral Water Hospital. As might be expected, many visitors come to spend the week-end in Bath. It would be difficult to find a quieter haven for an over-worked medical man, who has no lack of quick trains to carry him down for a few hours of restfulness. Incidentally he can inspect the bathing establishment, and will be able to obtain information beforehand as to special facilities and privileges from the Director, Mr. John Hatton. The mayoral chair of this ancient city is filled for the current year by one of the most popular medical men in Bath, Dr. Preston King.

Panel Incomes at Bradford.

IT has been so vehemently asserted by certain newspapers that medical men are amassing vast sums out of the insurance patients that it is interesting to have some precise figures by way of counterpoise. On the authority of the *Bradford Daily Telegraph*, it is stated that there are 126 doctors on the panel of the city of Bradford, and in nine months, that is up to October 12th, they have actually received from the Government £26,282 for ordinary and £2,021 for domiciliary services under the Act. By a simple process of division it is evident that the average for each medical man thus engaged is represented by the magnificent sum of £222 for nine months, or some £300 per annum, in return for arduous and responsible work of a highly-skilled nature. As a matter of fact, the actual remuneration ranges widely on either side of the £300, in proportion to the numbers of insured on each panel doctor's list. In Bradford there are six medical men who have over 3,000 on their list, six more have over 2,000, and thirty-two over 1,000. Until some way is found of a more equal division of labour, there will always be a tendency to overwork the popular panel doctor at the inevitable sacrifice of efficiency in the service. It needs little argument to show that the physical limitations of mortal man prevent him giving proper care and attention to more than a certain average of patients daily. Want of recognition of that simple fact robbed the old club practice of any real value, and a similar error will work disaster if allowed to creep into Insurance Act practice.

Foods, Proprietary Medicines and the Panel.

SOONER or later the question of patent medicines in relation to the Insurance Act will have to be threshed out. It is unlikely that the enormous trade interests concerned will abandon so attractive a field of operations. Nor, on the other hand, is the medical profession, nor, one would imagine, the Government likely to help the proprietaries. In Sheffield the matter has been settled, at any rate for the time being, on a basis that seems fairly satisfactory to all concerned. The Local Insurance Committee submitted the matter to a conference of chemists and medical men, who, after prolonged discussion, agreed to the following joint recommendations: (1) That no foods be prescribed or

dispensed; (2) that secret remedies shall not be prescribed or dispensed; (3) that practitioners on the panel shall be requested to prescribe as far as possible from the list of drugs in the tariff, and also to prescribe in reasonable quantities. The compromise has much to be said in its favour, and it deserves consideration by other Local Committees. At the same time it would be farcical to endeavour to guard the health of the people by a National Insurance Act that permitted the use of notorious quack medicines, pilloried by the medical profession and by courts of justice, while recognising the right of herbalists, Christian scientists and other unqualified persons to sign medical certificates valid under the Act.

A Wise Exclusion.

AMONG the several interesting matters brought up at a recent meeting of the West Riding Insurance Committee was the consideration of a letter from a "medical herbalist" requesting that insured persons might be allowed to make special arrangements for "treatment" by him. Some of the members present argued in favour of the recognition of such persons, since it was alleged that there were thousands of people in the Riding who believed in herbal treatment. It was further urged that the Act allowed Christian Scientists to act in connection with the treatment of insured persons, and that there were examinations which herbalists had to pass before setting up in "practice." Whatever were the original intentions of the framers of the Act it is inconceivable that they would, of their free will and accord, openly place herbalists and other unqualified persons under the Medical Acts upon the same level as medical practitioners for purposes of treatment. If such a principle were once adopted there would be no limit to the abuses that might be perpetrated in the name of the Government. Any pretender to medical knowledge, or any self-styled healer of disease, would then receive, as it were, official sanction to ply his doubtful trade and dupe his fellow-subjects without let or hindrance. The West Riding Insurance Committee may, therefore, be commended in deciding not to recognise "medical herbalists." It is to be hoped that a similar exclusion will be maintained by all insurance committees throughout the country.

Dangerous Pin-pricks.

IF it be true, in the case of medical diseases, that it is important to pay attention to small deviations from the normal, it is doubly so where surgical affections are concerned, more especially if pyogenic organisms be present. An inquest was held the other day at Leicester upon a hosiery spinner's foreman who died from septicæmia following cellulitis of the arm and shoulder resulting from a small septic abrasion upon the finger. From the evidence given it appears that the workers in the spinning trade frequently knock their hands upon the frames, inflicting trivial injuries, which, as often as not, are very lightly regarded. In the present case the Coroner remarked that it was the third he had had in a short time of death from blood-poisoning following a slight injury, and he considered that such abrasions, trivial though they might seem at the time, should be properly attended to and dressed. With the recommendation of the jury that notices should be posted up in factories drawing attention to the danger of neglecting small abrasions we heartily agree, for it would be quite an easy matter to arrange for the immediate application of a hot fomentation or a bathe in some warm antiseptic fluid pending medical inspection of the injury. It is lamentable to think that valuable lives may be sacrificed from the want of immediate attention to some trivial wound, which may be nothing more than a pin-prick. Most medical men can recall instances among students or colleagues of fatal septicæmia following a prick inflicted at an operation or a dressing, in spite of prompt attention.

LEADING ARTICLES.

THE COSTLINESS OF DRUGS.

A RELATIVELY high price is of course inseparable from not a few drugs and non-medicinal therapeutic agencies, and it is difficult to see how their cost can be lessened. The market price is determined by many considerations, such as the rarity of a given product, its complicated methods of production, its monopoly by means of patent processes or protected names, the smallness of available supply, and so on. In the case of some largely-used drugs it must be admitted that costliness constitutes a serious drawback, inasmuch as it handicaps the medical profession in its attempts to cure and to prevent human disease and suffering. Instances in point will occur readily to the minds of our readers. Take the case of iodine and the iodides, cocaine, quinine, tuberculin and salvarsan, all of them absolutely essential remedies in medical practice. They may all of them be termed expensive drugs, although in some cases the price has been considerably reduced in recent years. In the case of quinine we have an altogether indispensable remedy in the treatment of malaria, and one that lends invaluable aid in many other tropical diseases. Who can doubt that the former extremely high price of quinine was a calamity to mankind at large? Now, happily, owing to the enlightened policy of the Indian Government, vast plantations of the cinchona tree have been established in India, Ceylon and other British colonies and dependencies, with the result that the present price of one of the most valuable drugs known to medical science has been reduced to a fraction of its former cost. It is not for a moment suggested that the erstwhile high prices of quinine were due to the greediness of drug importers or producers. The rate was fixed by the scantiness and remoteness of the available supply of cinchona bark and by the imperfect nature of the methods of chemical production. Tuberculin furnishes an instance of a product that for some time commanded an excessively high price owing to the small supply obtainable. After more than twenty years it still retains its place among the actively-used and costly drugs, although, strange to say, its use is still, from a scientific standpoint, empirical. Salvarsan, on the other hand, ranks as one of the great medical discoveries, and stands on a precisely revealed scientific basis. Its price, unfortunately, has been so high as necessarily to limit its field of application. It is obviously beyond the

resources of panel practice, for instance, and, so far as that goes, in the treatment of the poorer classes generally, except in the wealthier voluntary medical charities. We understand that even in the richest institutions the cost of salvarsan has seriously restricted its use, while in the smaller hospitals it has been practically abandoned. Probably much the same applies to Poor-law medical practice, for it is more than likely that local boards would refuse to sanction any large expenditure on drugs that cost, say, 13s. to 15s. per dose of .4 gramme. It becomes, therefore, a fact of national importance that the market price of salvarsan and neosalvarsan has fallen about one-half. Radium comes under another category. There is reason to believe that the radium of the world has been "cornered" by a group of astute business men in order to keep up the price. The plea of cost of production is more or less of a fable; radium is widely distributed and can be produced at a fraction of the price now demanded for it. It is curious, by the way, to find that the enormous sum bestowed on the purchase of radium for charitable purposes in London is being applied to the treatment, at high fees, of well-to-do persons. Surely that inflicts an injury upon the medical profession that could not have been intended by the founders of the Radium Institute. Then, again, it is announced that radium water, obtained, presumably, by simple methods, is sold to the public at a rate which seems disproportionate to its real value. So absolutely beyond suspicion is the management of the Radium Institute that the mere mention of these points will probably lead to a careful revision of the conditions of a trust that may not improbably be fraught with great scientific issues at some future period. Like most economic matters, that of nigh-priced remedies leads one back to the fundamental question whether it would not be better in the long run for the State to control their administration in the interests of public health, that is, by the way of a State medical service.

CURRENT TOPICS.

Flannelette Safety.

ON the first day of this year an Act came into force which will probably save many young lives. It is called the Fabrics (Misdescription) Act, and it forbids anyone to sell a fabric, wrongly described as non-inflammable. Since the introduction of flannelette in 1885, there has been a large increase in the number of deaths from burns. In 1904 the number of deaths due to flannelette ignition was 412. A Coroner's Committee considered the subject in 1910, and this Act is the result. It is quite a simple Act. It in no way prohibits the sale of inflammable flannelette, but merely inflicts penalties on a man who sells inflammable material when asked for non-inflammable, and the standard of inflammability is reckoned by tests to be prescribed by the Home Office. To the non-legal mind it seems curious that traders could have gone on for twenty-eight years supplying dangerous material when specifically asked for another article without the incurrence of a penalty, and we hope this legislation will have the desired effect. Of course it presupposes some slight intelligence on the part of the public. It must ask for what it wants. The fact that by law it must get it cannot be too widely proclaimed. Although we trust that the flannelette deaths will decrease considerably during 1914, we are not too optimistic. The public can be very silly, and it is quite on the cards that it will take several years for it to learn to ask for what it would certainly wish to have if it took the trouble to think about it.

Insurance against Mumps.

PAROTITIS in the adult is apt to prove a troublesome, and occasionally a formidable, complaint. Apart from the infectious nature of the malady, it is somewhat humiliating to become the victim of what is usually regarded as one of the childish complaints. It is reported that a number of City clerks and others have insured themselves at Lloyds against the risk of loss consequent upon catching mumps, since several cases of the disease have occurred during the past few days. Higher rates are already being demanded. Those who have already had mumps are now being charged a premium of 10s. to secure the payment of £5 for each week of the next three months during which they might be disabled by a fresh attack, as compared with 5s. previously accepted. Those who have not yet had mumps are now charged 25s. to secure the same benefit as compared with 20s. quoted last week. The whole staff of one large firm have just been insured. As the quarantine period for mumps is twenty-five days and the period of isolation required is three weeks from the onset of the disease, such a scheme is quite a sound business proposition and one which might well be adopted in the case of other epidemic diseases which usually run a benign course.

The Young and the Stress of Life.

WHETHER we like it or not, the rush and tear of modern life enters into what should be the peaceful and orderly domains of the nursery and schoolroom. Indeed, the invasion of this restless spirit may be said to commence with birth, for the helpless infant is hurried into the world, often by artificial means, and almost as soon as it can breathe it is exposed to all manner of influences which tend to upset its tiny balance, mental and physical. Having adjusted itself to its surroundings as far as training and instinct permit, the unfortunate child is subjected to further increasing educative stimuli which, more often than not, result in the development of a nervous and irritable disposition. An interesting paper upon the subject was read last week by Miss H. Webb, M.B., before the Parents' National Educational Union at the London University, in which she pointed out the real dangers that exist in starving a child intellectually, instead of giving him "a full diet of wholesome ideas." The importance of an accumulation of wide knowledge for the prevention of nervous instability was rightly emphasised by Miss Webb, for it is certain that a rich store of interests serves to maintain that healthy mental balance which is so necessary to prepare the child for the stress of modern life.

Bathos.

DR. ELMER LEE, in *Health and Culture* (of America), is crusading against our cleanliness. He is propagating the order of the no bath. He says that bathing is an unnecessary habit, that man is an air animal, and that a bath-tub is an

enemy. England has beaten God's own country this time. Last year, Sir Almroth Wright made several statements which were generally taken as a declaration for dirt. Denunciations such as these seem superfluous, and argue no other quality than a certain amount of courage in those who utter them. The praise of bathing is a pious custom amongst us more honoured in the breach than the observance. Some men bathe daily, but some do not, and our feeling is that the latter are in the majority, and it can hardly be argued that those who omit the diurnal tub do so at the bidding of pure reason. Even in these islands baths are a comparatively modern fad introduced during the eighteenth century by travellers who observed the habit in the East and were eager for new sensations. The good old times may have placed cleanliness next to godliness, but then, perhaps, godliness was also neglected. The daily tub is æsthetically pleasant and hygienically helpful, but it is not a panacea for a nation's ills. Some men have a cold dip every morning to give them a subject of conversation in the winter, and their sense of truthfulness will not allow them to have the praise without the pain. All the same, their work is one of super-irrigation. Sensible men bathe because they like it, and for no other reason, and a custom thus founded is almost ineradicable. Not all the fulminations of a Lee nor the arguments of anyone else will turn our feet the narrow bath therefrom.

Another Influenza Epidemic.

ENGLAND is once again in the throes of a serious and widespread epidemic of influenza. That unpleasant fact has for some time past been forcing itself upon the attention of the medical profession, not a few of whom have themselves recently proved victims of this disastrous malady. For several months influenza of the gastro-intestinal type has been prevalent, a form of attack the real origin of which is often overlooked. Influenza is always a subtle and treacherous enemy. Without rhyme or reason it has suddenly reverted to its old-fashioned ways, that is to say, it lays its unhappy victim by the heels, prostrate in body and in mind, with a sort of woebegone despair to which the sorrows of the sea-sick are a fleabite. Needless to say, this form of the malady is one of the most dangerous. The heart muscle is almost invariably weakened, and the sufferer runs a deadly risk if he gets up and goes about his business instead of stopping in bed and treating himself to unstinted warmth, nourishment and stimulation, the common-sense as well as the scientific tripod of influenzal nursing. Failing these, the door is thrown wide open for pneumonia, heart-failure and the rest of the complications that prove so deadly in what is commonly regarded as a trifling ailment.

Inoculation in Pneumonia.

IN our last issue we referred to the first part of the "Report to the Rand Native Labour Association on the Results of an Inquiry into the Causation, Prophylaxis, and Treatment of Pneumonia," by Sir Almroth Wright, issued on January 2nd, in which the relative merits of drug and vaccine treatment of the disease were discussed. The concluding section of the report was published last week, and contains an account of experiments undertaken with the pneumococcus vaccine. It appears that the blood of the African native is inferior to that of the average European in that it is deficient in its immunising response towards pneumococcal infection, which disparity may be due, in part, to the absence of the disease in the native kraals. Consequently, pneumonia is seen at its worst amongst the newly-arrived natives, especially when massed together in compounds. This effect of a microbic infection upon virgin soil is not unknown among other communities, a heavy mortality being an inevitable result. Sir Almroth Wright recommends that prophylaetic inoculation according to a definite formula be applied as a routine measure to every native on recruiting, and that natives should in all cases be reinoculated after the expiration of four months. Preventive measures are of equal, if not greater, importance than therapeutic in dealing with such a disease under these peculiar circumstances. Further investigations are still urged in the treatment of pneumonia by vaccines before it is adopted as a routine measure, and the continued prosecution of research into therapeutic inoculation is regarded as essential to the attainment of the best results.

The Value of Heliotherapy.

AN excess of sunlight can hardly be regarded as a characteristic of the climate of the British Isles, at any rate, not in the neighbourhood of large cities. Attempts, therefore, to utilise the healing power of the solar rays must necessarily be somewhat limited in this country, except, perhaps, in certain favoured South Coast resorts. The use of light as a therapeutic agent is very old, but it cannot be said that much progress was made in this direction till Finsen brought the subject prominently before the profession. It is now some eleven years since Rollier established the first sanatorium for the systematic treatment of surgical tuberculosis by direct exposure to the sun's rays at Leysin, Switzerland. Some of the results of his treatment were reported to the recent International Congress of Medicine in London, and it must be admitted that they were most encouraging. The experiences of Rollier with the light cure at high altitudes enable him to state that the cure of surgical tuberculosis of the "closed" variety, in all stages, as well as at every age of life, can be accomplished. Progressively increased exposures to sunlight are given until a desired degree of pigmentation has been induced, the affected parts being immobilised, but all apparatus required for fixing joints, etc., is removed daily during the period of exposure. Even tuberculosis of the peritoneum and lymphatic glands has cleared up under the treatment, the only drawback of which is the length of time, and consequent expense, occupied in order to obtain results. The greatest success appears to have attended Rollier's methods at high altitudes, where the treatment has not to be constantly interrupted on account of changes of temperature.

The Coolidge X-Ray Tube.

THE announcement of the invention by Mr. William Coolidge, of Schenectady, of a new X-ray tube which, if it prove a success, will revolutionise the application of X-rays, is one of the greatest interest to radiologists and to all medical practitioners. Briefly, it may be said to consist of a tube in which ductile tungsten is employed throughout, the anode being made of the heavy metal and the cathode of the light metal. There is said to be no fluorescence in the Coolidge tube, but streams of charged particles from the tungsten anode and cathode, heated in a vacuum, are driven by a powerful current and the ray is formed. If it be found that the new tube will enable operators to

control their results better, it may prove to be a formidable rival of radium. At any rate, the discovery marks a great advance in the progress of roentgenology.

PERSONAL.

WE understand that it is the intention of the King and Queen to attend a matinée at the Palladium Theatre on Tuesday, March 17th, in aid of the Fund for the rebuilding of the Chelsea Hospital for Women, which will shortly be commenced on the new site presented by Earl Cadogan.

T.R.H. PRINCE AND PRINCESS ARTHUR OF CONNAUGHT opened the new buildings of the National Hospital for Diseases of the Heart in Westmorland Street, Marylebone, on Monday last.

SIR JOHN BROADBENT, BART., M.D., has been appointed Full Physician on the Staff of St. Mary's Hospital, Paddington.

DR. F. LANGMEAD, M.D., F.R.C.P.Lond., has been appointed Physician in Charge of Out-Patients, St. Mary's Hospital, Paddington.

SIR WATSON CHEYNE, BART., has been appointed Hunterian Orator at the Royal College of Surgeons of England for the year 1915.

LIEUT.-COL. C. W. R. HEALEY has vacated appointment in the London District and taken up duty at the Royal Herbert Hospital, Woolwich.

LIEUT.-COLS. R. HOLYOAKE and J. F. Donegan and Capt. H. C. Winkworth have been selected for service in India, embarking on February 11th.

MR. J. WALLIS GILL, M.R.C.S., L.R.C.P., of St. Germans, Cornwall, has been placed on the Commission of the Peace for the County of Cornwall.

PROFESSOR G. SIMS WOODHEAD, M.D., F.R.S., has been appointed Consulting Pathologist to the Royal National Hospital for Consumption, Ventnor, I.W.

MAJOR J. D. G. MACPHERSON has been appointed Deputy Assistant Director of Medical Services, West Lancashire Division, Territorial Force, from January 29th.

DR. J. A. GIBSON, of Newport, I.W., has been appointed Honorary County Medical Director of the Isle of Wight county branch of the British Red Cross Society.

SURGEON-COLONEL JOHN RICHARDSON, I.M.S. (retired), who saw service in the Bhutan expedition of 1864-66, hon. physician to the King in 1903, left net personalty £3,256.

DR. CONSTANTINE T. C. DE CRESPIGNY has been appointed Director of the Government Bacteriological Laboratory and Clinical Pathologist at the Adelaide Hospital, South Australia.

LIEUT.-COL. D. D. SHANAHAN, from India, has taken over the duties of Deputy Assistant Director of Medical Services, Eastern Command, in succession to Lieut.-Col. M. W. Russell.

MR. HAROLD L. WHALE, M.D., B.C.Cantab., F.R.C.S.Eng., has been appointed Surgeon to the Throat, Nose, and Ear Department of the Hampstead and North-West London Hospital.

DR. E. LINDSAY DUNN, of the Berkshire Asylum, Wallingford, has been elected Chairman of the newly-formed Association of Assistant Medical Officers of Asylums in England and Wales.

DR. GUSTAVE MONOD, M.R.C.P.Lond., of Vichy, has been commissioned by the French Ministre de l'Instruction Publique to study the organisation of post-graduate study in Great Britain and in the United States.

SIR RICKMAN GODLEE, President of the Royal College of Surgeons of England, has received a gold medal of honorary membership and the presentation medal of the National Institute of Social Sciences of America for notable service rendered to humanity.

PROFESSOR ARTHUR KEITH, F.R.S., will be presented with the Triennial Gold Medal of the West London Medico-Chirurgical Society at the forthcoming annual dinner thereof on Thursday, February 19th, 1914, at the Wharncliffe Rooms, Hotel Great Central, Marylebone Road, N.W., at 8 p.m.

COL. A. F. RUSSELL, who has just been placed on retired pay, has lately been Director of Army Medical Services in Egypt. He has had thirty-two years' service in the Army, and was all through the South African War, being mentioned in despatches and receiving the Queen's and King's medals with eight clasps.

THE centenary of the birth of Sir James Paget was duly commemorated on Sunday last in the Parish Church of St. Nicholas, Great Yarmouth, with which he and his family were intimately connected. The sermon was preached by his son, the Bishop of Stepney, and the service was attended by the Mayor and Corporation in state, the Master of Downing, and numerous delegates from medical and other societies.

MR. F. W. GAMBLE, manager of the West End branch of Messrs. Allen and Hanburys, Ltd., has just been elected on the board of directors. He has been connected with that firm for many years, having passed the major examination and taken the Pharmaceutical Society's bronze medal in the previous year. Mr. Gamble is a past President of the Chemists' Association, and for the last six years he has been one of the Pharmaceutical Society's Board of Examiners.

LIST OF CLINICAL LECTURES FOR 1914.

We have been favoured by promises of Clinical Lectures from the following Hospital Teachers and Post-Graduate Lecturers, to whom we tender our best thanks:—

P. H. ABERCROMBIE, M.D., Surgeon Central London Throat and Ear Hospital; Hon. Surgeon Royal Caledonian Institution.

HY. RUSSELL ANDREWS, M.D.Lond., M.R.C.P., Obstet. Physician, London Hospital; Lecturer on Midwifery and Diseases of Women, London Hospital Medical School.

ARTHUR S. BARLING, F.R.C.S., Hon. Surgeon to the Lancaster Royal Infirmary.

JAMES BERRY, M.B., B.S.Lond., F.R.C.S., Senior Surgeon and Lecturer on Clinical Surgery, Royal Free Hospital, Consulting Surgeon to the Alexandra Hospital for Children.

HENRY T. BEWLEY, M.D. F.R.C.P.I., Physician to the Adelaide Hospital, Dublin.

SIR JOHN BLAND-SUTTON, F.R.C.S.Eng., Surgeon to the Middlesex Hospital, Member of the Cancer Investigation Committee.

SIR JOHN F. H. BROADBENT, Bart., M.D.Oxon., F.R.C.P.Lond., Physician to Outpatients and Joint Lecturer in Medicine, St. Mary's Hospital, Paddington.

F. X. CALLAGHAN, M.D., Physician to Jervis Street Hospital, Dublin.

HARRY CAMPBELL, M.D., F.R.C.P.Lond., Phyician to the West End Hospital for Diseases of the Nervous System.

ALBERT CARLESS, M.B.Lond., F.R.C.S., Surgeon to King's College Hospital; Professor of Surgery in King's College.

EDMUND CAUTLEY, M.D.Cantab., F.R.C.P.Lond., Physician to the Belgrave Hospital for Children and to the Metropolitan Hospital.

SIR ARTHUR CHANCE, F.R.C.S.I., Surgeon to the Mater Misericordiæ Hospital, Dublin.

GEORGE L. CHIENE, M.B.Ed., F.R.C.S., Assistant Surgeon, Royal Infirmary, Edinburgh; Lecturer on Surgery, New School of Medicine, Edinburgh.

J. F. CHRISTIE, M.B., C.M., Lecturer on Skin Diseases, University of Aberdeen; Physician for Diseases of Skin, Royal Infirmary.

J. JACKSON CLARKE, M.B.Lond., F.R.C.S., Surgeon to the Royal National Orthopædic Hospital and to the North-West London Hospital.

EDRED M. CORNER, B.Sc.Lond., F.R.C.S., Surgeon in Charge of Outpatients, St. Thomas's Hospital; Surgeon to the Hospital for Sick Children.

FRANK C. CRAWLEY, F.R.C.S.I., Assistant Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin.

F. G. CROOKSHANK, M.D.Lond., M.R.C.P., Physician, Hampstead General Hospital; Assistant Physician, Belgrave Hospital for Children.

SIR J. HALLIDAY CROOM, M.D.Ed., F.R.C.P., Cons. Gynæcologist, Royal Infirmary, Edinburgh; Professor of Midwifery, University of Edinburgh.

JAS. DONELAN, M.B., R.U.I., M.Ch., Physician, Laryngologist and Aurist Italian Hospital, London; Honorary Physician, Royal Society of Musicians.

E. A. DORRELL, F.R.C.S.Eng., D.P.H., Assistant Surgeon, Royal Eye Hospital; Ophthalmic Surgeon, Eastern Dispensary.

F. CONWAY DWYER, F.R.C.S.I., Surgeon to the House of Industry Hospitals, Dublin.

T. W. EDEN, M.D.Ed., F.R.C.P.Lond., Obstet. Physician to Charing Cross Hospital; Surgeon, Chelsea Hospital for Women.

WM. EWART, M.D.Cantab., F.R.C.P.Lond., Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children.

G. FITZGIBBON, M.D., F.R.C.P.I., Gynæcologist to the Royal City of Dublin Hospital.

JAS. S. FOWLER, M.D., F.R.C.P., Physician, Edinburgh Royal Hospital for Sick Children.

HERBERT FRENCH, M.D.Oxon., F.R.C.P.Lond., Assistant Physician, Pathologist and Lecturer, Guy's Hospital.

ARTHUR E. GILES, B.Sc Lond., M.D., F.R.C.S.E., Surgeon, Chelsea Hospital for Women; Gynæcologist, Prince of Wales' Hospital.

ALEX GOODALL, M.D., Ch.B., F.R.C.P.Ed., Lecturer on Physiology in the Edinburgh School of Medicine.

GEO. L. GULLAND, M.D.Ed., F.R.C.P., Physician to the Royal Infirmary, Edinburgh; Physician to the Victoria Hospital for Consumption.

E. C. HORT, M.D., F.R.C.P.Edin., Member of the Advisory Council of Medical Research.

J. HUTINEL, M.D., Professor of the Paris Faculty of Medicine; and Physician to the Hopital des Enfants Malades.

HENRY JELLETT, M.D., F.R.C.P.I., Master of the Rotunda Hospital Dublin.

ROBERT ARMSTRONG-JONES, M.D., F.R.C.P.Lond., F.R.C.S., Lecturer on Mental Diseases, St. Bartholomew's Hospital.

J. M. MUNRO KERR, M.D., F.F.P.S., Muirhead Professor of Midwifery and Gynæcology, Glasgow Univ.; Obstetric Physician, Glasgow Maternity Hostpital.

J. A. KYNOCH, M.B., F.R.C.S., Professor of Obstetrics and Gynæcology, University of St. Andrews.

FREDERICK LANGMEAD, M.D., F.R.C.P.Lond., Physician to Out Patients; St. Mary's Hospital, Assistant Physician and Pathologist, Royal Free Hospital,

R. MURRAY LESLIE, B. Sc., M.D., Senior Physician, Prince of Wales's General Hospital; Lecture in Medicine, North-East London Post-Graduate College.

J A. MACEWEN, M.B., C.M., F.R.F.P.S., Senior Assistant to Regius Professor of Surgery in the University of Glasgow.

JOHN MACINTYRE, M.B., C.M.Glasg., F.R.M.S., Surgeon for Diseases of the Throat, and Nose, Glasgow Royal Infirmary.

A. A. MCCONNELL, F.R.C.S.I., Assistant Surgeon to the House of Industry Hospitals, Dublin.

H. L. MCKISACK, M.D.R.U.I., M.R.C.P.Lond., Physician to the Royal Victoria Hospital, Belfast.

G. NORMAN MEACHEN, M.D., Physician to Blackfriars Skin Hospital; Physician for Skin Diseases, Prince of Wales's General Hospital.

H. CRICHTON MILLER, M.D., Ch.B.

THOS. K. MONRO, M.D., M.Ch., F.F.P.S.Glas., Physician and Clinical Lecturer, Glasgow Royal Infirmary; Regius Professor of Medicine, University of Glasgow.

K. W. MONSARRAT, M.B., C.M.Ed., F.R.C.S., Lecturer on Clinical and Operative Surgery, and Dean of the Faculty of Medicine, Liverpool University.

R. OSWALD MOON, M.D.Oxon, F.R.C.P.Lond., Physician to the Western General Dispensary and to the Hospital for Diseases of the Heart.

J. RUTHERFORD MORISON, M.B.Ed., F.R.C.S.Eng., Senior Surgeon to the Newcastle-on-Tyne Royal Victoria Infirmary; Professor of Surgery, University of Durham.

J. D. MORTIMER, M.B.Lond., F.R.C.S., Anæsthetist to the Royal Waterloo Hospital, St. Peter's Hospital and Throat Hospital.

SIR BERKELEY MOYNIHAN, M.B.Lond., F.R.C.S., Surgeon to Leeds General Infirmary; Professor Clin. Surgery, Univ. Leeds.

J. LOCKHART MUMMERY, B.C.Camb., F.R.C.S.Eng., Surgeon to St. Mark's Hospital for Diseases of the Rectum, and to the Queen's Hospital for Children.

H. OLIPHANT NICHOLSON, M.D.Aberd., F.R.C.P.Ed., Assistant Physician to the Edinburgh Maternity Hospital. Exam. in Midwifery, Aberdeen University.

SIR LAMBERT H. ORMSBY, F.R.C.S.I., Surgeon to the Meath Hospital Dublin.

FREDERICK S. PALMER, M.D., F.R.C.P.Lond., Physician to the West End Hospital for Diseases of the Nervous System.

ALFRED R. PARSONS, M.D., F.R.C.P.I., Physician to the Royal City of Dublin Hospital.

Sir R. W. PHILIP, M.D.Ed., F.R.C.P., Physician to the Edinburgh Royal Infirmary, Physician to the Royal Victoria Hospital for Consumption.

D'ARCY POWER, M.A.Oxon., F.R.C.S., Surgeon to, and Lecturer on Surgery at, St. Bartholomew's Hospital.

SETON S. PRINGLE, F.R.C.S.I., Surgeon to Mercer's Hospital Dublin.

G. ERIC PRITCHARD, M.D., B.Ch.Oxon., Senior Assistant Physician, Queen's Hospital for Children; Physician, City of London Hosp.

URBAN PRITCHARD, M.D.Ed., F.R.C.S.Eng., Emeritus Professor of Aural Surgery, King's College, London.

A. MAITLAND RAMSAY, M.D.Glas., F.R.F.P.S., Ophthalmic Surgeon, Glasgow Royal Infirmary, Ophthalmic Lecturer, Glasgow University.

G. D. ROBERTSON, F.R.C.P.Ed., Physician Superintendent to the Royal Edinburgh Asylum, Morningside; Lecturer on Mental Diseases University of Edinburgh.

ALBERT ROBIN, M.D., Professeur Agrégé, the Faculty of Medicine; Physician to the Beaujon Hospital, Paris.

J. S. Y. ROGERS, M.B., C.M.Ed., Physician to the Dundee Royal Infirmary, Lecturer on Diseases of Children, University College, Dundee.

AMAND J. ROUTH, M.D., F.R.C.P.Lond., Obstetrical Physician and Lecturer on Midwifery, Charing Cross Hospital; Consulting Physician, Samaritan Free Hospital for Women.

ROBERT J. ROWLETTE, M.D., Physician to Jervis Street Hospital, Dublin.

F. M. SANDWITH, M.D., F.R.C.P.Lond., Gresham Professor of Physic; Lecturer to the London School of Tropical Medicine.

P. R. DE SANTI, F.R.C.S.Eng., Aural Surgeon and Surgeon for Diseases of the Throat, Westminster Hospital.

ROBT. SAUNDBY, M.D., F.R.C.P.Lond., Professor of Medicine in the University of Birmingham; Physician to the Birmingham General Hospital.

T. CLAYE SHAW, M.D., F.R.C.P.Lond., Emeritus Lecturer on Psychological Medicine, St. Bartholomew's Hospital.

JAS. SHERREN, F.R.C.S.Eng., Surgeon to the London Hospital and to the Poplar Hospital for Accidents.

SYDNEY STEPHENSON, M.B., C.M., F.R.C.S.E., Ophth. Surgeon, Evelina Hospital, and to the Kensington General Hospital.

PURVES STEWART, M.D.Ed., F.R.C.P.Lond., Physician to Westminster Hospital; Physician to West End Hospital for Nervous Diseases.

G. F. STILL, M.D.Cantab., F.R.C.P.Lond., Physician for Diseases of Children, King's College Hospital, Physician to Out-patients, Hospital for Sick Children.

W. H. B. STODDART, M.D., F.R.C.P.Lond., Resident Physician and Medical Superintendent, Bethlem and Royal Bridewell Hospitals.

R. ATKINSON STONEY, F.R.C.S.I., Surgeon to the Royal City of Dublin Hospital.

J. M. G. SWAINSON, F.R.C.S., Asst. Surgeon Westminster Hospital; Surgeon to the Bolingbroke Hospital.

G. A. SUTHERLAND, M.D.Ed., F.RC.P.Lond., Physician to the Paddington Green Children's Hospital. and Royal National Orthopædic Hospital.

JAMES TAYLOR, M.D.Ed., F.R.C.P.Lond., Physician to the National Hospital for the Paralysed and Epileptic, and to the North Eastern Hospital for Children.

H. CAMPBELL THOMSON, M.D., F.R.C.P.Lond., Physician to the Hospital for Epilepsy and Paralysis, Maida Vale.

A. F. TREDGOLD, F.R.C.S., Consulting Physician to the Association for the Feeble-minded; Medical Expert to Roy. Commission on the Feeble-minded.

A. H. TUBBY, M.S.Lond., F.R.C.S., Surgeon-in-Charge of Orthopædic Department, Lecturer on Clinical Surgery, Westminster Hospital.

DAVID WALSH, M.D., Senior Physician, Western Skin Hospital, London.

C. GORDON WATSON, F.R.C.S.Eng., Surgeon to the Metropolitan Hosp.; Assist. Surgeon to St. Bartholomew's and St. Mark's Hospitals.

ARTHUR J. WHITING, M.D., M.R.C.P.Lond., Dean of the N.E. London Post-Graduate College; Physician to the Prince of Wales' Hospital, and Mount Vernon Hospital.

R. H. A. WHITELOCKE, M.D.Ed., F.R.C.S.Eng., Litchfield Lecturer in Surgery, Oxford University; Surgeon to the Radcliffe Infirmary.

WYATT WINGRAVE, M.D., Pathologist to the London Polyclinic and to the Central London Throat and Ear Hospital.

ANDREW WYLIE, M.D., C.M., Surgeon to the Central London Throat, Nose and Ear Hospital.

CLINICAL LECTURE

ON

DIAGNOSTIC ERRORS IN CLINICAL PATHOLOGY. (a)

By WYATT WINGRAVE, M.D.Lond.,

Pathologist, London Polyclinic, etc.

THE test tube is just as liable to error as the stethoscope. Your attention to-day will therefore be drawn to a few of the most likely mistakes which may be made in the course of routine work whether at the bedside or in the laboratory.

Let us first consider urine. A specimen may be turbid. Is this temporary or permanent? Should it clear in response to the usual tests, a wide range of organic troubles may at once be excluded, but should turbidity, however slight, persist, then cells or bacteria may be found, which must be verified by the microscope, and no reliance should be placed upon such a macroscopic sign as ropiness or flocculence.

No substance is so often the cause of error as albumin. This is perhaps due to the use of nitric acid, hot or cold. Both are fallacious and may cause serious misunderstanding, and its evidence must always be accepted with doubt, especially when the reaction is but slight.

Albumose or peptone may give the same reaction, Albumose may be present in any urine, but specially during pregnancy, and has not infrequently been the cause of unnecessary alarm. The safest test is either Esbach's picric solution or a saturated solution of salicyl sulphonic acid, Each gives a definite precipitate, but, on heating, should it become clear, it is albumose, if turbidity remains or increases it will be albumin. This proteid reaction is often seen in athletes after a violent effort, but it is due chiefly to serum globulin and is very transient. Albumosuria may occur in any febrile state, therefore the differential test should always be made, especially in suspected diphtheria, when albumin is an early and important sign.

Sugar in the urine is often perplexing, as there are many substances which have reducing power. One of the commonest causes for anxiety is pentose. This occurs generally in the autumn with cherry and plum consumption. Chemically it is indistinguishable from glucose, but it is rarely in marked quantity, and successive examinations will prove it to be only transient in appearance.

There are many reactions employed for sugar, but it will be found far more satisfactory to become familiar with one and to stick to it rather than to risk confusion by trying unaccustomed methods. Personally, I prefer Nylander's bismuth solution as a preliminary test, which is very delicate and gives a fair idea as to the proportion of sugar present and so the amount of dilution required in applying a quantitive test. Fehling's solution is by far the best for general use, and every confidence may be placed in it providing everything is clean.

In true glycosuria sugar is generally present in the blood, but is considered difficult to demonstrate, therefore is not attempted as a routine. Such, however, is not the case, for even the faintest trace of sugar in the blood can be shown by a very simple method. Take two test tubes, place in each about half-an-inch of a weak solution of methylene blue and the same volume of liquor potassæ. Add a few drops of blood from the patient's thumb to one, and some of your own blood to the other. Warm both tubes; should sugar be present the blue either diminishes in intensity or disappears entirely, while the control tube will be unaffected. This test is particularly useful when applied to nasal discharge which is suspected to be cerebro-spinal fluid. A positive reaction never occurs with an ordinary catarrhal flow. The presence of acetone is easily confounded with kreatinin since they give identical reactions with the nitro-prusside test. Acetone, however, alone gives iodoform when added to a mixture of liquor potassæ and iodine solution.

In cases of bacteriuria it is very important that the reaction should be carefully tested. Litmus is unreliable, because it not only affords no definite proportions, but may give the conflicting amphoteric reaction. To obtain any good from urotropin the urine must be acid and should be kept above the index 5. To ascertain this, take 10 c.c. of urine and add to it 5 drops of a 5 per cent. solution of phenol phthalein in alcohol. Then titrate with decinormal sodium hydrate. The amount required to produce a pink colour is the index. To ensure liberation of formalin the index should be not less than 5. Great care should be taken in examining urine films for evidence of pus. In most cases of bacteriuria leucocytes are or should be present. But they are not necessarily pus corpuscles. Pus is the product of a suppurating focus, such as occurs in surgical cases, while in simple bacteriuria leucocytes only with perhaps a few bladder cells will be found. In pus, however, there will not only be marked degeneration of the leucocytes, but there will also be present lymphocytes, endothelium and plasma cells in large numbers.

Much confusion may arise in the examination of blood if carelessly collected. It should not be taken from the ear lobe, because there is so much elastic tissue present which automatically closes the puncture and necessitates "milking." This causes an excess of plasma and gives an erroneous idea of the relative proportion of all the corpuscles. It is far easier and more satisfactory to collect from the *back* of the thumb, where the flow is easily obtained and controlled. Care must also be taken in spreading the film evenly, since leucocytes tend to collect at the sides and end, while lymphocytes select the centre, being smaller.

The use of cigarette paper in making films is the cause of many mistakes, since the leucocytes adhere to it. There is no better spreader than the sharply fractured edge of a slide. In the absence of a hæmoglobinometer a very reliable idea of any deviation from the normal may be obtained by comparing the patient's blood with your own. Collect a small drop of each on a piece of fine white filter paper and compare in strong daylight. Anæmia or polycythæmia may often be so recog-

(a) Lecture delivered at the Polyclinic.

nised, and as a preliminary to a more precise examination.

We will now consider a few points in connection with sputum.

Tubercle bacilli are associated with many difficulties. It is easy to say that they are present, but it is a great responsibility to affirm that they are absent. Therefore specimens from a suspicious case should be treated with antiformin and centrifuged. Further, the specimen should be taken from the early morning expectoration.

Many errors may be made owing to our imperfect understanding of what constitutes an acid-fast bacillus.

It was once taught that a bacillus which retained the fuchsin after a bath of 25 per cent. sulphuric acid must be tubercle. This is not so. It must be alcohol as well as acid-fast. That is it must pass through a thorough bath of alcohol as well as acid before counter-staining in order that it may be unequivocally diagnosed as tubercle.

Simply acid-fast bacilli are very common. They are found in chronic ear discharges, in atrophic rhinitis, fæces, lingual, umbilical and preputial accumulation, in butter, cheese, and, in fact, any solution in which bacilli grow in the presence of fat. These are artificially acid-fast, while tubercle is naturally or intrinsically acid-fast due to a waxy material in its structure. This material requires heat for its proper staining.

By far the most reliable method of demonstrating the tubercle bacillus is the picrin process, in which I have perfect confidence. After fixing the film by heat, it is further fixed by a bath of saturated solution of picric acid in alcohol. Stained with hot carbol fuchsin (basic), washed in 25 per cent. sulphuric acid, alcohol, and finally counter-stained in the picric solution again.

By this means only tubercle bacilli are stained of a deep garnet colour. They are easy to find and easily recognised either in films or sections. Ordinary acid-fast bacilli are unstained, therefore there need be no confusion.

The presence of albumin in the sputum has been advanced as diagnostic of tuberculosis. This is, however, very unreliable, since albumin and other proteids can be extracted from nearly every specimen, and its use is not to be recommended.

The examination of tissues for malignancy demands much care and judgment, especially polypi, which may not afford the slightest suspicious appearance except in a limited area. Therefore a serial inspection should be made from all parts of every suspected specimen. Differential diagnosis between sarcoma and granuloma is often very difficult, yet reliance can be made on sections stained by Pappenheim's solution (methyl green and pyronin), which demonstrates plasma cells beautifully, as well as mitotic figures and all nuclear aberrations.

Errors in diagnosis may be considerably reduced by :—

(1) Comparison with normal fluids, *e.g.*, urine. Blood.

(2) Comparison with checks or controls. Diphtheria, tubercle bacilli, gonococci, etc.

(3) Careful testing of new reagents, stains, etc.

(4) Always employing confirmatory tests.

The best way to avoid error is to check every test with a control. As, for instance, in the case of a doubtful urine or blood reaction with a normal sample. Bacteria with verified films and a few slides of tubercle bacilli should always be kept for testing new staining solutions.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Alfred Mantle, M.D.Durh., M.R.C.P.Lond., Consulting Physician to the Royal Halifax Infirmary. Subject: "The Causes and Symptoms of Mucous Colitis and its Treatment by Irrigation as done at Harrogate and Plombieres."*

ORIGINAL PAPERS.

THE RETRACTION RING AS AN OBSTRUCTION IN LABOUR. (*a*)

By ROBERT JARDINE, M.D., F.R.F.P.S.,
Professor of Midwifery, St. Mungo's College, Glasgow, Physician and Gynæcologist, Glasgow Maternity Hospital.

IN 1876, Bandl first drew attention to the fact that in obstructed labour the upper part of the uterus thickened while the lower part thinned out, and that a distinct ledge or ring formed at the junction of these two parts. He considered that the ring marked the situation of the internal os, and that the thinned-out part of the uterine wall was the elongated cervix. In 1886, Schroeder, in his frozen sections, showed that the ring formed at a higher level than the os internum, and also that it formed in normal labours, and was not merely the result of an obstructed labour. Further observations by Barbour and Webster, Blumreich, Eardly Holland, and others, have left the question of the situation of the ring not yet settled. Clinical experience of a number of cases has confirmed the author in the belief that it is not at the internal os that the ring forms, but several inches higher up, the height depending upon the amount of stretching which the lower uterine segment has undergone. The peritoneum covering the lower part of the uterus is loosely attached, and where the peritoneum becomes closely adherent marks the upper limit of the lower uterine segment and the position of the ring. From a clinical point of view, the exact situation of the ring is not of so much importance as the fact that it does form, and that it may cause an exceedingly dangerous obstruction in labour. In some cases it is not the primary cause, but the result of the obstruction; in others it is itself the cause of the obstruction. While it is a rare complication of labour, it is commoner than is generally supposed.

Cases fall into three groups, according as the retraction ring forms (1) in front of the presenting head; (2) above the presenting head; or (3) in breech presentations; and each group presents the following characteristics:

1. Retraction ring in front of head.—*Diagnosis.*—There is no apparent obstruction to the advance of the head, and yet the labour is delayed, though the uterine contractions are strong and frequent. On palpation of the abdomen the head is found well above the brim of the pelvis, and cannot be pushed down. If the abdominal wall is thin the ring can be felt, but with a thick wall it may not be felt. On vaginal examination the os is found to be dilated and the lower uterine segment opened up, but some three inches or so above the os a distinct ridge is felt running round a portion or the whole of the uterine cavity in front of the head. During a pain this ledge does not relax, but becomes more prominent and prevents the advance of the head. The membranes may or may not be ruptured. If they are intact they protrude into the vagina, and may even be seen at the vulva. In any case the ring undoubtedly forms before the membranes have ruptured. As to the cause

(*a*) Read before the Glasgow Medico-Chirurgical Society, Dec. 19th, 1913.

of the formation of the ring, it should be noted that a spasmodic condition of the os is occasionally met with, where the circular fibres round the os have not been inhibited, and these fibres contract along with the fibres of the main body of the uterus, so that the os actually gets smaller instead of larger with each uterine contraction. There is considerable resemblance between the fibres round the os and those of the retraction ring, and what causes spasm in the former may cause it in the latter. Spasmodic contraction of the os is generally supposed to be due to an irritant which acts reflexly.

Prognosis.—If the condition is recognised in time, both mother and child should be saved; but, unfortunately, in many of the recorded cases a definite diagnosis was made only when exhaustion had set in and there was little chance of saving either mother or child.

Treatment.—If the child is alive, Cæsarean section is the proper treatment. Full doses of morphia or opium have been recommended, but the author has never seen any effect in causing relaxation. Manual dilatation has been advised, but the hand is powerless in such cases. Incision of the ring has been recommended, but it would be impossible to prevent the incisions extending, and this would end in rupture of the uterus. Hydrostatic bags are useless as they cannot be introduced high enough to bear upon the ring. If the child is dead it can be delivered by craniotomy, using an instrument which will permit of powerful traction being made. If the shoulders are caught the clavicles should be cut.

2. Retraction ring above the presenting head.—*Diagnosis.*—If the patient is thin, palpation will reveal the presence of the ring. An internal examination will show that the head is high up, but is not obstructed, and on passing the fingers beyond the head the distinct ledge will be felt in front of the shoulders.

Causes.—The membranes rupture before there is any dilatation of the os, and the uterus soon becomes moulded round the child. During the slow dilatation of the os retraction takes place and the ring forms round the neck of the child; but there must be more in it than that, because many cases are seen where the membranes rupture early, and many hours elapse before the os is fully dilated, and there is no obstruction to the advance of the body. There must be a determining cause, but it is difficult to say what it is.

Prognosis.—If the condition is recognised early the chances for both mother and child should be good; but if it is recognised only after attempts to deliver have failed, the prognosis is unfavourable, especially for the child.

Treatment.—Opiates seem to have no effect in causing relaxation. Manual dilatation is useless. If the forceps will hold it may be possible to drag the shoulders through, but not always. When the child is alive undoubtedly the proper treatment is Cæsarean section. It will be necessary to divide the ring to allow extraction of the head, as occasionally has to be done in contracted pelvis, where the membranes have been ruptured for some time and retraction has occurred. When the child is dead, a crushing instrument, which will take a powerful grip of the head will permit the shoulders to be dragged through. Division of the clavicles will facilitate this. Version is of course contra-indicated.

3. In a breech presentation, when the legs are extended, impaction generally occurs. The cause of the impaction is the retraction ring gripping the child below the knees, so that its legs and feet are hitched above the ring. In these cases the membranes rupture early, the whole of the liquor amnii drains away, and the uterus becomes moulded round the child. By the time the os is fully dilated the ring has become a very palpable ledge inside the uterine cavity, and with each uterine contraction it contracts and grips the child so firmly that descent is prevented. In these cases the risks to the mother are very small if proper precautions are taken, and to the child they are not much greater than in an ordinary breech case which requires artificial delivery.

As to *treatment*, traction upon the breech by forceps, fingers, fillets, etc., is of little use, and a blunt hook should never be used on a living child. With the patient deeply anæsthetised, the flattened hand should be passed in carefully in front of the child until a foot is reached, which is then swept inwards over the front of the child and brought down, this must be done with care, as the lower uterine segment is thinned out, and if care is not taken it may be ruptured. When the leg is brought down traction should be made upon it, while an assistant keeps up firm pressure upon the fundus of the uterus to prevent the arms going up and to keep the head well flexed. If the arms are caught they must be relieved by sweeping them over the front of the child, and the after-coming head must be dealt with in the usual way.

INTESTINAL DISINFECTION IN ALIMENTARY TOXÆMIA.

By FRANK E. TAYLOR, M.A., M.D., F.R.C.S., D.P.H.,

Lecturer in Bacteriology, University of London, King's College; Pathologist and Curator, Royal Westminster Ophthalmic Hospital; late Pathologist, Chelsea Hospital for Women.

THE recent discussion on "Alimentary Toxæmia" at the Royal Society of Medicine, in which nearly sixty speakers took part, may be taken as an indication both of the importance of the subject and also of the large amount of attention which is being bestowed upon it at the present time.

Hitherto many vague ideas have clustered round the term "Alimentary Toxæmia," and, as Dr. Hale White (1) points out, "an illness due to any poisons absorbed anywhere from the mouth to the anus is strictly an alimentary toxæmia, but the phrase would hardly cover a case of opium poisoning."

In the present article I would prefer to limit the use of this laxly used term, and to give to it a somewhat more precise meaning, and would define alimentary toxæmia as the sum total of those conditions of ill-health produced by the absorption from the alimentary canal of chemical poisons of known or unknown composition, due to abnormal metabolism or bacterial activity, the blood having served as the channel of distribution to the tissues which are affected by the poison.

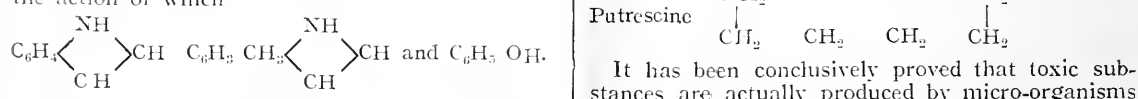
In the fœtus *in utero* and in the newly-born child alimentary toxæmia is quite unknown, since the contents of the alimentary canal are sterile, the physiological processes of digestion have not yet been called into activity, hence no chemical changes have taken place and no toxic substances have been produced.

Soon after birth, however, micro-organisms gain access to the alimentary tract, and from this time onward the manifold signs and symptoms of alimentary toxæmia gradually increase throughout the remainder of life.

In the breast-fed child the predominant intestinal bacteria are the Bacillus bifidus of Tessier, an anaerobic, Gram-positive acidophilic or acetogenous organism—one, that is to say, which is able to grow in acid media, fermenting lactose with the

production of acid. A very similar organism also found in the intestine of the child is the Bacillus acidophilus of Moro. In the adult, however, these acidophilous organisms are replaced by fermentative and putrefactive bacteria. These putrefactive organisms are proteolytic, splitting up the nitrogenous constituents of the intestinal contents into their cleavage products—proteones, peptones, amino-acids and toxic amines. These putrefactive proteolytic organisms play the chief *rôle* in the production of intestinal putrefaction, and have been much studied by Metchnikoff and his pupils. They form a group of proteolytic anaerobes and include *B. perfringens, B. sporogenes,* and *B. putrificus.*

The further breaking down of these cleavage products of proteolysis is brought about by *B. coli* and its congeners the coliform organisms, by the action of which



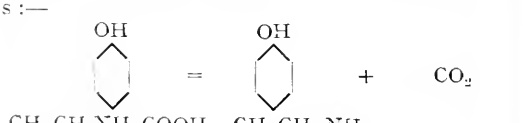
Indol Skatol or Methylindol. Phenol

are produced.

Our knowledge of the proteolytic activity of the putrefactive group of bacteria has been greatly extended by researches which have followed up the work of Abelous (2) and of Professor Dixon and myself (3).

In 1906 Abelous obtained from putrefying horse flesh a pressor substance which possessed a markedly similar physiological action to that of adrenalin. In 1907 Professor Dixon and I found a similar pressor substance in the extracts of placentæ, which had undergone incipient putrefaction. These two pressor substances were subsequently identified by Barger and Walpole (4) as iso-amylamine and para-hydroxy-phenyl-ethylamine respectively.

Para-hydroxy-phenyl-ethylamine, or tyramine, is formed by the action of putrefactive bacteria on hydroxy-phenyl-propionic acid or tyrosine, by a process of decarboxylation, CO_2 being split off, thus :—



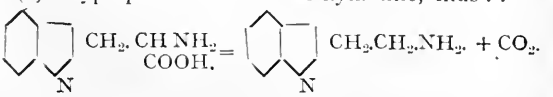
Tyrosine. Tyramine.

Now tyrosine is normally formed during pancreatic digestion, but in aseptic pancreatic digestion, no tyramine is produced from it, as it is only produced by putrefactive organisms. Barger and Walpole succeeded in obtaining tyramine from tyrosine containing media when inoculated with fæcal bacteria.

This experiment conclusively proves that amino-acids, which are normally produced in the alimentary canal during protein digestion, and which are physiologically inert substances, may be converted by fæcal bacteria into toxic substances, which on absorption may lead to general poisoning of the system, unless destroyed or rendered innocuous by the natural protective mechanism of the body.

Other amino-acids which may be decarboxylated similarly in the intestinal tract by the action of putrefactive micro-organisms with the production of toxic amines are :—

(1) Tryptophane into Indolethylamine, thus : :—

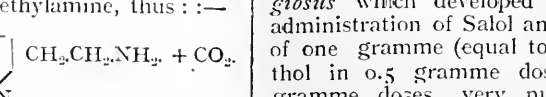


Tryptophane. Indolethylamine.

(2) Leucine into Iso-amylamine, thus :—

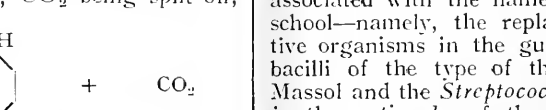
Leucine. Iso-amylamine.

(3) Phenylalanine into Phenylethylamine, thus:



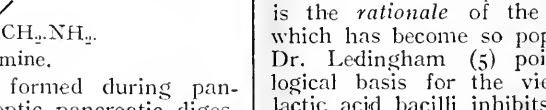
Phenylalanine. Phenylethylamine.

The toxic substances also produced from the corresponding amino-acids by the action of putrefactive bacteria in the bowel are :—



Cadaverine

and



Putrescine

It has been conclusively proved that toxic substances are actually produced by micro-organisms in the intestinal canal, and that these toxic substances are absorbed. That toxic phenomena are not more frequently observed is due to the various defensive mechanisms which the body possesses, and it would seem that it is only on the failure of these defensive mechanisms to play their part or on the excessive production of these toxic substances that symptoms of poisoning supervene.

Probably these toxic substances are most commonly produced in excessive amounts in conditions of colon block and intestinal stasis. The successful treatment of this class of case demands the removal of the cause of the stasis, be it a mechanical blocking from growth, bands, etc., or a neuro-muscular one with paresis of the intestinal wall. The appropriate surgical, medical, or dietetic measures must be employed here.

In the absence of these conditions attempts may be made to limit the production of toxic products of bacterial origin in two ways. Of these one is associated with the name of Metchnikoff and his school—namely, the replacement of the putrefactive organisms in the gut by harmless lactic acid bacilli of the type of the *Bacillus bulgaricus* of Massol and the *Streptococcus lactis* of Kruse. This is the *rationale* of the soured milk treatment which has become so popular. Unfortunately, as Dr. Ledingham (5) points out, "a bacteriological basis for the view that the activity of lactic acid bacilli inhibits that of the putrefactive organisms is still lacking."

The other method consists in an attempt to diminish the content of putrefactive and other bacteria within the intestinal tract. Complete sterilisation of the intestine is as undesirable as it is impracticable.

The question as to whether the germ content of the intestinal canal can be modified by the administration of bactericidal substances by the mouth without causing undesirable toxic effects is one which has been much disputed, and upon which there is little uniformity of opinion, even at the present time.

Stern (6) many years ago administered various antiseptics to patients suffering from various diseases, followed by a dose of *B. prodigiosus* culture, the stools being plated at various intervals of time, and the number of colonies of *B. prodigiosus* which developed was noted. After the administration of Salol and of Naphthalin in doses of one gramme (equal to 15 grains) of β-naphthol in 0.5 gramme doses and camphor in 0.1 gramme doses, very numerous colonies of *B. prodigiosus* developed. Only after the administra-

tion of calomel in large doses was there a scanty development of *B. prodigiosus* colonies.

In these experiments, then, salol, naphthalin, β-naphthol and camphor were found useless as intestinal disinfectants, the only tested substance which exerted a definite effect being calomel in large doses. Obviously calomel in large doses, because of its purgative effects and its toxicity, is quite unsuitable as a routine intestinal disinfectant. The problem was attacked in another way with newer germicidal substances in the bacteriological laboratories of King's College in a series of experiments, to be published later, by Professor Hewlett. The number of *B. coli* in the stools of two normal adults was found to average about ten millions per gramme. To one of these individuals was given one gelatin-coated capsule, containing three minims of kerol—an emulsified disinfectant of high carbolic acid co-efficient and low toxicity containing a di-phenyl nucleus—three times a day after meals, the other individual taking ten grains of salol thrice daily in a similar manner.

At the end of three days there was no appreciable alteration in the *B. coli* content in the stools of either individual. The Kerol was now increased to two three-minim capsules thrice daily, the salol remaining as before.

The number of *B. coli* in the stools of the kerol-taking individual rapidly dropped to about ten thousand per gramme, that of the salol-taking individual remaining as before at about ten millions. These results have been confirmed by experiments performed elsewhere, the *B. coli* content of the stools having been reduced by 99 per cent. by the administration of two three-minim capsules thrice daily after meals.

These results were obtained upon healthy adults taking a normal amount of food; the same results would, doubtless, be obtained with smaller doses in invalids on smaller and more restricted diets.

Bacteriological experiments have thus shown that the oral administration of suitable disinfectants does diminish the bacterial contents of the intestine. The knowledge of this fact ought undoubtedly to be made use of, more frequently than is the case at present, in the treatment of the numerous class of cases in which the symptoms are due to the absorption of toxic substances from the lumen of the alimentary canal, as the result of excessive bacterial fermentations therein.

That very decided benefit may result by the adoption of this line of treatment may be gathered from papers by Warner (7) on "Intestinal Flatulence," by Ringrose (8) on "The Bacillus Coli in Pathological Conditions," and others. It is to them that I would refer the reader for the convincing evidence that exists of the clinical value of this method of treatment.

In conclusion, the weight of evidence—both bacteriological and clinical—abundantly proves that the oral administration of a suitable disinfectant in efficient doses markedly diminishes the production of those toxic substances of bacterial origin, the absorption of which into the blood stream gives rise to the protean manifestations of Alimentary Toxæmia, and that we have now at hand a ready means of keeping those manifestations in check.

THE BIOLOGY OF SYPHILIS. (a)

BY J. E. R. McDONAGH, F.R.C.S.

THE BIOLOGY OF A CHANCRE.

AFTER a patient has exposed himself to infection, one or more spores gain access to the skin, in which they develop. When sufficient cycles, which comprise the life history of the Leucocytozoon syphilidis, have been completed the patient develops a sore. As the host can form no immediate protective bodies, there is no limit to the number of sores which may be present, the number depending upon the different points of entrance of the organism. In roughly 30 per cent. of cases of syphilis there is more than one primary sore, the most I have ever seen being eighteen.

When the spore has entered, it seeks out a connective tissue cell, to the protoplasm of which it gains access. Therefore the connective tissue cell is the first cell to be attacked in syphilis, consequently the brunt of the attack and the resistance offered will affect these cells, with the result that they will multiply rapidly.

Connective tissue cells later become fibrous tissue, hence the explanation of the so-called induration of chancres. The induration is relative, since a sore may appear before the connective tissue cells have had time to form fibrous tissue, or a sore may develop in loose tissue, in which, did fibrous tissue form, it would be scarcely noticed.

As a sore may appear before there is any induration, the incubation period of syphilis must vary greatly, the approximate limits being from eight days to six weeks or more. As the connective tissue cells are first attacked there will be no great demands for leucocytes, and as phagocytosis plays no part in protozoal infections there will be no pus and no necrosis. Therefore, if a sore occurs it will be an erosion and not an ulcer. A chancre may even be met with in which the surface epithelium does not break.

As a primary sore most usually affects regions which are containing large numbers of saprophytic organisms, it may easily become infected or even phagedænic; in this case, instead of a simple erosion, there may be a big ulcer.

If the saprophytic organisms attack the sore early and be active, they may succeed in annihilating the leucocytozoon. This explains the fact that some phagedænic sores are not followed later by further evidences of syphilis. In any case, the onset of phagedæna alters the sequence of the disease, usually by delaying the outbreak of the rash, sore throat, etc.

Herein lies the indication for removing a primary sore when possible, or for cauterising those that cannot be so handled.

THE BIOLOGY OF THE CAUSE OF SYPHILIS.

The spore is a small body consisting almost entirely of nuclein, which, as such, is powerless; therefore it is obliged to enter a cell.

The lipoid-protein forms a colloidal membrane, in which the spore, or, as it is now called, the trophozoite, develops.

In this envelope the nucleus either buds to form sexual merozoites, or it divides and subdivides to form an asexual spore cyst. The former course occurs in every case of syphilis, while the latter has only been found in the lymphatic glands from severe cases of early generalised syphilis. An asexual spore cyst may bud to form daughter spore cysts, by which time the parasite has become extracellular owing to the degeneration of both the protoplasm and the nucleus of the connective tissue cell.

In the other mode of development of the trophozoite, about seven to fifteen bodies are formed, each one presenting a lecithin-globulin envelope of its own,

(a) An abstract of a paper read before the West London Medico-Chirurgical Society, December 5th, 1913.

so in the full stage of development no background is seen at all. When fully developed, the cell bursts, allowing the sexual merozoites to escape, when they become male and female gametocytes. One of the points which determine the sex of the merozoites is doubtless the quantity of lecithin-globulin that each bud takes with it, since the male gametocytes are more optically active than the female—a physical property which most lipoid-proteins exhibit, and which serves well for picking out the syphilitic bodies in a section.

Both the male and female gametocytes are motile, but not flagellated; the male consists of three nuclear bodies, while the female contains a nucleus at her upper end and one or two very actively motile blepharoplasts at her lower end. By the time the female has reached the size of a red blood corpuscle she loses her blepharoplasts, becomes stationary, and, in those females which are about to be fertilised, the nucleus comes from the upper pole, takes a central position, and practically fills up the cell. The blepharoplasts of protozoa are probably analogous to the nucleoli of nuclei; as in both cases one is dealing with a mass of nuclein encased in a lipoid-protein envelope.

The male gametocyte, on the other hand, usually enters a large mononuclear leucocyte, wherein the three nuclear bodies increase in size to develop into a coil; and from each nuclear body a number of spirochætæ arise like the spokes of a wheel from its axle. The spirochætæ break loose, and each can then be recognised as a true spirochæta pallida. In the extracellular development, each nuclear body divides and subdivides, so that a rosette-like appearance is formed. Several bodies may break away *en masse*, in the shape of a chain, which ultimately breaks up into distinct coccus-like forms, or discrete coccus-like forms may break away from the start. Each coccus-like body contains two rods, which give it the appearance of a diplococcus, and these rods develop into thick and unevenly-coiled spirochætæ, which eventually become typical spirochætæ pallidæ.

The intracellular development is found in every syphilitic lesion so far examined, while the extracellular development has only been found to occur in chancres and condylomata, two lesions which are especially rich in spirochætæ. Therefore, provided the circumstances are favourable for the formation of spirochætæ, the male gametocyte will develop extracellularly, by which means more spirochætæ are formed.

The immature spirochæta which is first formed in this extracellular route resembles the refringens type; therefore it is very probable that those observers who considered that the refringens and pallida were stages of the same organism were in part correct.

In cultures the male gametocyte develops extracellularly.

Fertilisation, again, does not always appear to take place in the same stereotyped manner, as in some cases the spirochæta appears to enter the female nucleus, wherein it becomes lost, or to become connected with the female nucleus by a skein. In both cases the nucleus, which contains both male and female elements, migrates again to the upper pole; such a cell is a zygote.

Only one spirochæta enters the female, and it takes either side of an hour to become entirely lost to view. While entering, the whole cell is in active motion, but once the spirochæta has entered the whole cell comes to a sudden standstill and appears to become covered with a mantle. This mantle has strong reducing properties, and is of a lecithin-globulin nature, with an extra supply of fatty acid. The result is that in zygotes the lecithin-globulin envelope is very much more marked than in the morphologically identical female gametocytes, and in consequence thereof they are more highly refractile.

A few minutes after impregnation, a polar body is shot out with great force from the cell, and again another after an interval of a minute or two. During the extrusion of the polar bodies, the cell is very actively motile, but it becomes stationary immediately after the second has been ejected. The polar bodies contain a lecithin-globulin protoplasm, and also some nuclein.

The nucleus of the zygote divides and subdivides into sporoblasts; the sporoblasts may further divide and subdivide *in situ* to form sporozoites, or a sporoblast may escape and form sporozoites on its own. For those who wish for a fuller description of the life-history of the organism of syphilis, I must refer them to my two illustrated articles which were published early this year (1 and 2).

The points which have been brought up against my conception of the life cycle of the organism of syphilis are that the spirochæta pallida has been obtained in pure culture, and that animals have been infected with such cultures. The spirochæta pallida I have cultured myself and proved that it develops extracellularly. To-day too much value is being placed upon cultures; especially is this the case where protozoa are concerned. With bacteria and fungi the greatest morphological differences exist between the same organism in the body and in cultures, not to mention the variations produced by the different media upon which they are grown. How much greater, then, must be the difference when a highly developed organism like a protozoon is compared growing "in corpore" with its growth "in vitro." A comparison is wholly unjustifiable since we know practically nothing about the cultural properties of protozoa in general.

Concerning the statement that animals can be infected with syphilis from cultures of the spirochæta pallida, first of all, what evidence is there that the animal is really syphilitic? Secondly, how is it known that only spirochætæ were injected? And, thirdly, is it not known that if a sufficient quantity of wax or fat is injected into a rabbit's testicle, fine particles of the same will be found later in the bloodstream and in the urine? But yet that animal is not suffering from "cerosis" or "liposis." Therefore more proof must be forthcoming, that when a rabbit is injected with myriads of spirachætæ, before we can say that it is suffering from "spirochætosis."

THE BIOLOGY OF THE PROTECTIVE MECHANISM OF THE HOST AGAINST THE LEUCOCYTOZOON.

I will now endeavour to explain how the body protects itself against syphilis, how drugs act in helping to cure it, and why nerve tissue, when it is attacked, leads to a practically hopeless state of affairs.

The cell which the host elaborates to protect itself from the syphilitic organism is the plasma cell. This cell is also called forth in any chronic inflammation, such as tuberculosis or the chronic inflammation which may be produced by a piece of silk or wax. In all instances the plasma cell is morphologically the same, and although its gross action may be similar in every instance, it is nevertheless specific in each case.

Take, for example, three plasmomata, one caused by syphilis, another by tuberculosis, and the third by a foreign body. Give an injection of salvarsan, and then make sections of all three again, when, on examination, it will be found that only the plasma cells in the case of syphilis have altered.

To explain this specificity, we must probe the chemistry and physico-chemistry of the plasma cell. This may be best done by calling attention to what I have described as the "oxygen chain." Before doing so I must first acknowledge the assistance I have derived from Unna's work on the bio-chemistry of the skin. (4)

Each link of this chain will be made up of free oxygen and a ferment which activates it in varying degrees, according as to whether the first or last link of the chain is being dealt with. The first link is the red blood corpuscle, which contains free oxygen and a peroxydase; the ferment action is further increased by the iron in the hæmoglobin.

It is a curious feature that oxidising enzymes have their action increased by metals: attention need only be drawn to the extraordinary accelerating action manganese has upon some plant oxydases in support of this statement.

Red blood corpuscles travel everywhere, so that

every tissue can be supplied with oxygen in the active state.

The next link in the chain is a mast cell, one of the functions of which is doubtless to supply the basal cell layer of the epidermis with the active oxygen for the tyrosine-tyrosinase reaction which results in the production of pigment, which is one of the protective mechanisms of the body.

Note how mast cells are increased in urticaria pigmentosa, ephelides and all known pigmentary affections of the skin. Another function is doubtless to supply the next link with free active oxygen—namely, the nuclei of the cells of inflammation.

The accelerating element in the mast cell is possibly sulphur. Nuclei contain free oxygen and a ferment for activating the same, which is nothing like as strong as the peroxydase in the first two links; since it is easily destroyed by formaldehyde.

Iron is no doubt the accelerator of the enzyme action in the nuclear link. The oxygen in the nucleus is used by the protoplasm of the cell and the nucleolus.

The last link in the chain is the protoplasmic, which contains oxygen, but no peroxydase. The activator probably comes directly from the nucleus and indirectly from other cells which contain peroxydases through the blood serum.

The accelerator of the enzyme action is the element contained in the drug which is prescribed against the infection.

The lesions of syphilis may vanish without treatment, due to the ferment action of the serum, and of the protoplasm of the plasma cells.

The protoplasm of plasma cells is rich in lipoid-globulin, and it is well known that lipoids are activators of ferments; therefore in the protoplasm of plasma cells and in the serum the host has the means of overcoming the parasite. Treatment assists the host's resistance by acting as an accelerator of the ferments, and therefore destroys the parasites indirectly.

What the ferment is which destroys the Leucocytozoon is not quite clear, and the probable one can be arrived at better by exclusion, as at present no actual proofs of any certain one are forthcoming. The syphilitic parasite consists of a lecithin-globulin envelope which encases nuclein; therefore it may be *a priori* thought that the ferment is either a lecithase or a protease.

A lecithase unfortunately exists in normal serum, which makes testing for a specific one difficult, but as a result of several experiments which I have undertaken with both the serum and cerebro-spinal fluid, I have come to the conclusion that there is no specific lecithase. The globulin fraction is certainly not specific, as Abderhalden's test, as is used in pregnancy, when applied to syphilis, does not come off; therefore there is no specific protease.

All we know at present is that the protoplasm of plasma cells contains oxygen. We know further that lipoids and metals will accelerate an oxidising enzyme; therefore there is some ground for assuming that this oxidising enzyme abstracts some oxygen from the lecithin-globulin envelope of the parasites which, to protect itself, will call upon the oxygen in the nucleus underneath, which it can easily do as oxygen in nuclei is free, with the result that if the oxidising ferment is powerful enough all the free oxygen will be abstracted from the parasite with its consequent death. Such an explanation is extraordinarily simple: in fact, it is its simplicity which makes me think that it is correct, for the more I have thought upon how the body protects itself the more I am convinced that it is not nearly so elaborate as we have been led to believe.

After all, why should such a terribly complex ferment as a lecithase or protease be manufactured specifically against syphilis? Supposing another protozoal disease sprang up in our midst to-morrow, the body would be ready to protect itself and it could not possibly, in the short time at its disposal, manufacture highly complex specific ferments. A point strongly in favour of my view that the syphilitic protozoon and probably all other organisms which cause diseases are destroyed by oxidising ferments, is the fact that if the temperature of a case of syphilis reaches and remains for some time at 40° C., the symptoms will vanish; now 40° C. happens to be the optimum temperature for most oxydases.

A most interesting point now crops up, namely: why are the spirochætæ destroyed quicker than the other phases and so quickly by salvarsan?

I have proved by chemical means than the male gamete or spirochæta pallida has the strongest reducing action of all the phases. In *in vivo* staining it shows a marked affinity for methylene red, and it increases the reducing action of the female cell after impregnation.

In this reducing action lies the solution of two problems: (*a*) Why the male cell and not the other cells stain with silver nitrate in Levaditi's method of staining, and (*b*) why the action of salvarsan is more marked upon the male cell.

The reducing action is due to an unsaturated fatty acid—a substance in which the male cell is especially rich, for two reasons: (*a*) Because it is the result of an intracellular development; (*b*) because it has a very important function to perform, namely, that of impregnation. In other phases where combustion is less active and the cells are more or less in resting forms, the fatty acids are more likely to be saturated than unsaturated.

The more unsaturated a fatty acid is in a complex, the more free OH-, or hydroxyl groups, will there be.

On to these free OH-groups different chemical substances can become attached; therefore the spirochæta pallida, owing to the fact that it contains free OH-groups, can have its lipoid-envelope altered by substances which combine immediately therewith.

In staining tissue with silver nitrate, in order to get a black colour, two things are necessary: one is that the silver must be taken up; the other is that it must be reduced *in situ*. Owing to the free OH-groups in the lipoid-envelope of the spirochæta pallida, the silver is readily taken up and reduced by the pyrogallic acid. In the other phases, on the other hand, there are no free OH-groups to take up the silver, so they therefore cannot stain black. The action of salvarsan is also probably to be explained in this way.

The arsenic fixes on to the free OH-groups and robs the colloidal membrane of oxygen, hence the death of the organism. As there are no free OH-groups in the other phases, salvarsan cannot touch them. The destruction of the other phases is brought about by the ferment action of the serum and of the protoplasm of the plasma cells. Therefore, the action of salvarsan upon the spirochætæ is a direct one, and upon the other phases an indirect one. This explanation obviates the necessity for the word "receptor," which carried us no further than we were before its introduction.

From all that has gone before it will be at once understood why syphilis is so hard to cure, for the simple reason that the spore contains little or no lecithin-globulin and, therefore, as a spore it is potentially harmless and so is not touched immediately by the host's ferments. In course of time, however, the spores are vanquished, owing to the continued oxidising efforts of the host, and this supports the statement that I have more than once made, namely, that, broadly speaking, syphilis is cured not by the treatment we give, but by the resistance and protective machine of the host, which we assist by the treatment.

How Nervous System is Attacked.

Finally, why is the nervous system attacked in the peculiar way it is?

It is highly probable that nerve cells are only influenced by the spirochætæ. Now the spirochætæ, as may be remembered, are rich in unsaturated fatty acids, or, in other words, consist of a lipoid-protein coat which is unsaturated and will, therefore, snatch up anything that comes in its way. It will snatch up fats and lipoids, carbohydrates and proteins.

Fats and lipoids, and possibly carbohydrates, as such, and in the form of cerebrosides, are important chemical constituents of nerve cells. Therefore, their

abstraction will lead to nerve degeneration. In the same way, nerve cells can take up substances and enable them to become part and parcel of their highly complex lipoids—amongst others, metals. Therefore, it is at once clear why arsenic in the form of salvarsan, when injected into the theca, causes nerve degeneration.

If the above explanation is correct it may not be necessary to talk of primary neuronic degeneration, which has always been more or less of an enigma.

Applying what has already been said, it will be seen that the neurone degenerates, because its chemical molecule has been upset by the abstraction of vital atoms by the syphilitic parasites.

There it not much evidence to show that there is such a thing as a syphilitic toxin; and of all diseases with which we are acquainted, syphilis is the one which appears to be the least toxic.

GENERAL.

You may wonder why I have made no reference to the Wassermann's reaction or the luetin cutireaction.

The *rationale* of the Wassermann's reaction is not understood, it is doubtful whether our present interpretations of its results are correct, and recently I have succeeded in being able to make a reaction positive or negative at will.

The luetin reaction is not specific, and I have been able to obtain positive reactions in cases of syphilis with other substances. Moreover, a positive result does not tell us more than that the patient has had syphilis, it does not indicate that the disease is actually active. Tests—however perfect they may be to-day—will be capable of being improved or supplanted by something better to-morrow; therefore they can never be absolutely accurate.

A laboratory diagnosis can never be more than mere confirmatory evidence of a clinical diagnosis.

Most of the tests cannot be applied in the primary or most infectious period of the disease; therefore if syphilis is to be diminished, it will only come about by the training of the present and future generation in their clinical work.

Small-pox has been practically stamped out, not because of elaborate laboratory tests, nor even by treatment, but by prevention.

The same with syphilis. Unless our attention is first paid to those who have not got the disease, and then to those who are sources of infection, the scourge will never diminish.

In my opinion nothing will be achieved by having public laboratories, etc., and unless the Royal Commission the whole of the medical profession and the public realise that the last word on syphilis has not been said, but that daylight is only just beginning to peep through—then in ten, twenty, thirty and more years we shall have just as much syphilis as we have to-day.

A broader and more critical view of every knotty little problem is very sorely needed, and let our motto be "that what was done to-day, can be improved upon to-morrow."

THERMO-THERAPEUTICS.

BY PROFESSOR M. A. ZIMMERN, M.D.
[SPECIALLY REPORTED FOR THIS JOURNAL.]

PART II.

THERAPEUTIC EFFECTS.

THE therapeutic action of diathermy appears to be analgesic, decongestive and revulsive. It gives excellent results, notably against the symptom of pain; hence its employment in painful affections—sciatica, lumbago, facial neuralgia, and the various forms of arthralgia and arthritis. Berndt and Laqueur have in like manner obtained encouraging results in achillodynia and talalgia. Similar results have also been obtained in the articular manifestations of gout; while, in gonococcal arthritis, Belot procures the analgesic action only, the actual lesions not appearing to be modified in any way. In cases of bacillary arthritis, neither Bergonié, nor Belot, nor ourselves have been able to obtain any result. In the painful arthropathies, in chronic articular rheumatism, the analgesic effect appears fairly constant. Some authors have doubted the persistence of this result; our own personal observations have, however, led us to form the contrary opinion. Bergonié has noticed that in fibrous arthritis a diminution of swelling accompanied the analgesic effect. The same author has signalised, in a case of chronic pleurisy, suppression of the pains and a subsidence of the exudate. He also reports remarkable amelioration of the gastric crises in a tabetic case, and a similar result has been obtained by Nagelschmidt. Varet commends himself for his own employment of intrarectal diathermy, applied with Dormer electrodes and at an intensity of 700 milliampères, to diminish the congestive tumefaction of hæmorrhoids, accompanied with outflow of blood. In all these cases, and also in those to which we are to refer subsequently, we may ask ourselves whether heat is the sole effective agent; or whether we are not actually utilising, in addition to the Joule effect, some other property of high-frequency currents which has hitherto been ignored.

Notable improvement in cases of chronic aortitis has elsewhere been recorded, and diminution of the volume of the heart in a certain number of cases of cardiac dilatation has been demonstratively followed out by orthodiagraphy. Indeed, at the early period of our own researches we have often placed on the condenser bed patients affected with such circulatory troubles as Raynaud's disease; angiospasm, evidenced by coldness of the extremities; cryæsthesia, etc. Le Gendre pointed out, a long time ago, the effects of high-frequency currents in antagonising the cryæsthesia of patients' affection with the hypertension of arterio-sclerosis. He then stated that: "High frequency has the advantage of diminishing cutaneous angiospasm and permitting more copious irrigation of the tegumentary surface, and rendering patients less morbidly sensitive to cold." These results should not surprise us, inasmuch as we are opposing to the causative vaso-constriction of that condition the vaso-dilator action of the thermal contribution offered by the condenser bed. The same reaction enables us to explain the diminution of the dyspnœa of effort, vertigo, sensation of cold, palpitation accompanied by precordial anguish, etc., which may be observed in subjects of arterio-sclerosis after treatment. The dyspnœa of effort may be so far reduced that patients who had previously been unable to ascend a staircase without panting are enabled to do so with ease at the end of some weeks; and are able to enjoy prolonged promenade exercise, which they had been obliged to dispense with before. In patients affected with angina or asthma we often note, in a similar way, a marked diminution in the number and intensity of the crises. Such results have also been testified to by Nagelschmidt in cases of bronchial and of nervous asthma.

The fact is worthy of note that we are able, by systematic increase of the intensity of the current and prolongation of the sittings, to transcend the effect of vaso-dilatation and provoke defence against the heat by transpiration; but, as a rule, it is not desirable to apply so high intensity. Thus, from the means of defence which it calls into activity in the human organism, it would appear that the high frequency current should prove useful wherever there is an indication for decongestion of the internal organs, or an increase of the activity of the peripheral circulation.

Bergonié has quite recently drawn attention to the utilisation of diathermy in cases in which it is desirable to offer an organism a supplemental contribution of energy in the form of sensible heat. In comparing two organisms, one of which produces enough heat to maintain its own homothermy in the medium in which it radiates its calories; while the other, in a surface contact at which considerable loss of heat occurs, is constrained, in order to maintain its normal

thermal equilibrium, to proportion the intensity of its internal combustion to its external loss of heat; and is thus obliged to borrow the necessary energy in considerable degree from alimentary materials, in consequence of which overwork of the organs is forced upon the individual: of the digestive tube, the lungs and the heart—in order to digest, assimilate, and consume the enormous quantity of thermogenic aliment necessary under such conditions—Bergonié maintains that: instead of giving to such organism aliments which it is obliged to digest, assimilate, and consume so laboriously; we can make it absorb, directly and *in nature*, the equivalent quantity of heat. Nobody will, of course, have taken seriously this badinage, inspired by the general Press; and which tends to represent the method as a means of maintaining nutrition by replacing alimentation with heat infused into the organism. Is it not sufficient to recall the fact that the needs of cellular life demand an alimentary minimum proportional to the living mass of the organism, and to the activity of the metabolism of that mass? According to Lefevre, this minimum should be 1,500 per twenty-four hours, in the case of a normal man, of the 2,500—3,000 calories of the daily ration; that is to say, about half the quantity.

An organism in a state of depression, and containing but a poor proportional quantity of living matter, requires but an inferior quantity of aliment; and the surplus, the balance necessary to equilibrium (Bergonié), can be furnished by diathermy, which effects the penetration of heat *en nature* into the organism. Thus does Bergonié explain the use of the employment of diathermy in cases in which the organism is found in a state of hypothermy. Up to the present, our practice has been limited in those cases to protection of the patient against the cold; but, is it not more logical to supply him directly with heat? It is according to this claim that the hypothermy of the algid period of certain formidable diseases, the terminal hypothermy of chronic maladies, the almost physiological hypothermy of the old, and the hypothermy of copious hæmorrhages, would all appear to be justifiable cases for the application of diathermy. "Every time," says Bergonié, "that the general application of diathermy has been adopted with malingering, criminal, marasmatic, feeble or hypothermic subjects, I have seen the temperature rise, and with this an increase of weight, of arterial pressure, and of strength. I have found their alvine motions become regular, their alimentation become less intensive, more easily adjusted, and more varied. I have seen those organisms which had been in a state of *misère physiologique* become capable of both physical and intellectual work, of defending themselves better, and, above all, of having no need of diathermy after the return to the normal condition."

In order to obtain this result, Bergonié practises bi-quotidian sittings of forty minutes each; and an effective intensity of 2—3 ampères. With the apparatus employed, this intensity enables us to give the individual more than 3,000 calories an hour; that is to say, a quantity in a single hour greater than that of his alimentary ratio per day.

Berndt and Müller have proposed to utilise the hyperæmia produced by local diathermy for the purpose of increasing the sensibility of tissues to the X-rays. According to Müller, we may in this way produce in a given area a sort of permanent hyperæmia which sensitises the tissues on which we wish to bring to bear the action of the Röntgen rays.

Surgical diathermy, or electro-coagulation, is employed for the destruction of pathological tissues. It has been utilised by Doyen especially for the destruction of malignant tumours. Doyen based his practice in this department on the fact that neoplastic cells lose their virulence between 50° (122° F.) and 55° (131° F.), while healthy cells are destroyed at about 60° (140° F.). But it is evident that this margin is too narrow to furnish a sharply defined line of demarcation for the necrosis that we wish to obtain. There is no doubt that electro-coagulation has the advantage, in the treatment of cancer, of separating the diseased tissues without opening the vessels; but, on the other hand, the elimination of large blocks of coagulated tissues may bring serious suppurations in its train. Besides, the method does not protect against recurrence. French surgeons are still very much divided in opinion regarding the practical interest of this procedure.

Electro-coagulation has been employed in the treatment of lupus, with, possibly, a greater degree of success (Nagelschmidt). The cicatrices left by this mode of treatment are, perhaps, less neat than those obtained by phototherapy, but the instantaneous thermal effects spare the patients the numerous, even interminable, sittings required by the Finsen method.

Bergonié has employed electro-coagulation, after cocainisation of the root of the finger, in the endeavour to procure cicatrisation of an ulcer produced by chronic radiodermitis. The lancinating pains, which were propagated to the shoulder, disappeared; that portion of the ulcerated surface which was treated by electro-coagulation cicatrised, and was re-covered with a supple and healthy skin. We know, unhappily, that this result has not proved permanent.

It now remains for us to say some words on the practical realisation of the arrangements of the high-frequency armamentarium which are capable of producing large quantities of heat. With the high-frequency apparatus now in current use we can attain to about 1.5 ampères in direct application of diathermy. This intensity may suffice for local applications, or for the condenser bed; the only inconvenience which accompanies arrangements of this kind is that their high tension—of 20,000 to 40,000 volts—may produce somewhat dangerous sparks which may spring from the person of the patient to surrounding objects. What has specially led to criticism of the employment of those apparatus is that their power is relatively feeble—the term *power* being understood in its physical sense—of *work done in unit of time*. We know, in fact, that each spark which passes gives rise to a series of waves; and that the interval between two successive series of such waves is approximately 200 times as long as the duration of each of the series of waves itself. The phenomenon is comparable to the vibrations of a bell, which would be perceptible to the ear during some seconds; and of which the tongue should strike but every quarter-hour. To augment the power of the high-freqency current, it was indicated that: either the intensity of each series of waves should be increased, or that the number of sparks should be augmented. But in augmenting the difference of potential necessary for the charge of the condenser, in order to increase the intensity of the current of discharge, we may pass the limits of intensity within which the currents of high frequency are inoffensive to the motor nerves, and so risk the production of spasmodic contractions. The same result could be obtained by increasing the capacity of the condensers; but this would also have the effect of increasing the length of the wave, and we know that contractions may appear if we lower the frequency. Thus the indication was to have recourse to a mode of procedure capable of diminishing the proportion of time lost; in other words, to increase the number of sparks. To effect this purpose two methods suggested themselves:—

(1) Utilisation of the waves in the manner adopted in Poulsen's arrangement, in which the oscillations of an arc are utilised which has also a derived current bearing a self and a capacity. Some German apparatus are constructed according to this principle.

(2) The production of a great number of disruptive sparks, short, rapidly extinguished, and appearing under feeble tension; for, in diathermy, the tension does not require to be high, and the apparatus used give little more than 2,500 to 3,000 volts with 800,000 oscillations per second. In order to avoid the formation of the arc, which favours ionisation in the interval of sparking, and also the heating of the dielectric, we may, as Broca has pointed out, produce the spark in a carburetted medium—hydrogen, coal gas, vapour of alcohol, or vapour of ether. Thanks to this arrangement, the pathway of the spark is not heated. In other systems the destruction of ionisation is effected by a magnetic field or bellows, and, in the apparatus of Siemens and Halske, the extinction is produced by the cooling due to the great mass of the segments of

the sparker. In Broca's apparatus, constructed by Gaiffe, the distance of the sparking is from 2 to 3 millimetres.

A double spark has also been substituted, in series, for the single one. This divides the spark, and, by reducing the length of each of the resulting segments, gives a better result. In those apparatus, the condenser is proportioned to the feeble tensions which it has to support. But, whatever is done, a proportionally very great period of inactivity remains between the successive series of waves; the period of activity of the system being to that of repose in the proportion of 1 : 30.

For the local application of diathermy, and for the employment of the requisite apparatus, the electrodes constitute a balancing ratio, which constitutes a delicate question. For local applications it is necessary to use broad electrodes, which are placed in front of and behind the region to be treated. In order to avoid the formation of small, disagreeable sparks at the points not sufficiently adherent, and more especially if we employ the Arsonval-Gaiffe form of apparatus, we make sure that the electrodes are perfectly coapted; a good pressure produced by application of elastic bands is absolutely indispensable. But the question must be asked: Is it necessary to employ naked electrodes of flexible metal which may be adapted to all irregularities of the surface of the skin, as Bergonié advises; or is it necessary to employ the moist electrodes which are used in galvanisation?

It is certain that moist electrodes provoke a considerable elevation of the temperature of the skin; they inevitably become heated, in spite of their good conductibility, and very soon become unbearable. Besides, they soon become dried, and their substance being carried to a high degree of temperature, is then capable of producing burns. Electrodes of naked metal, well supported in position by elastic bands, are preferred by Bergonié; but they do not diminish the resistance of the skin. Nevertheless, when kept covered with a napkin soaked in water they remain cool; the water penetrates by virtue of capillarity and maintains a suitable humidity beneath the face of the electrode.

Laquerrière and Delherm have suggested placing in contact with the integument a metallic web, which they cover with a mattress of moistened bibulous tissue. The metal is thus placed in contact with the skin; and this latter profits, nevertheless, by the humidity of the electrode; and, moreover, the mass of water cools the skin.

For our own part, we have obtained very good results with electrodes formed of radio-active earth, which also can be easily replaced by clay. The latter has the great advantage of permitting perfect coaptation with the skin, on which it moulds itself perfectly. It does not become heated in the process, but to a quite insignificant degree; and its humidity always suffices to ensure good conductibility of the integument.

OPERATING THEATRES.

MIDDLESEX HOSPITAL.

COMBINED ABDOMINO-PERINEAL EXCISION OF THE RECTUM.—MR. SAMPSON HANDLEY operated on a woman æt. 64, and performed a combined abdomino-perineal excision of the rectum. The patient was by no means robust, and had suffered from asthma for the last thirty years. The symptoms of the carcinoma dated back for nine months. It was situated a finger's length above the anus and had not caused obstruction nor fixed the rectum. Prior to the operation 500 million polyvalent staphylococcus vaccine and 10 c.c. anti-colon bacillus serum were administered. The operation took one hour and twenty-five minutes. The pelvic floor was reconstructed by joining the cut edges of the meso-rectum and bringing back the uterus to fill in the gap which still remained anteriorly. The peritoneal cavity was not drained, but free drainage was provided for the pelvic cellular tissue.

Mr. Handley attributed the favourable result of the case largely to the use of his method of giving saline by the colon. The upper divided end of the colon brought out at the colostomy opening was not re-opened, but a No. 12 rubber catheter was tied into it, and until the opening of the colon on the fifth day, this catheter was used alternately as a channel for saline, which could not be rejected by the patient, and as a flatus tube.

The patient's pulse after the operation was 84, and it fell to 72 the same evening. The following day it was 68 and 64 on the two occasions that it was observed. The temperature never rose above 99.6, and the patient made an uninterrupted recovery. About five weeks after operation, practically no suppuration had occurred in the pelvis and the abdominal wound had healed throughout by first intention. The interest of the case lay chiefly, Mr. Handley said, in the patient's age, since the operation in cases above 60 had been attended by a very high mortality.

Mr. Handley drew special attention to the method of giving the saline, which, in his opinion, would practically abolish death from shock following the operation. He said that the method was extremely simple, but he considered that lowering the present high mortality of the abdomino-perineal operation was of such very great importance that he felt quite justified in calling attention to the method. He stated first that his practice was invariably to bring the divided colon out through a stab incision in the left inguinal region as he felt certain that attempts to bring it down to the anus were very dangerous. After the colon has been divided between clamps by the thermo-cautery and closed by the basting stitch method reinforced by a purse-string suture, he makes a stab incision in the inguinal region and brings through the blinded upper end of the colon, which he then fixes in position. When the abdominal portion of the operation is finished and before commencing the perineal portion, he marks out an area of about $\frac{1}{3}$ in. in diameter of the protruding surface of the end of the colon by means of a purse-string suture which takes up the peritoneal and muscular coats. Through the centre of this area he makes a stab incision into the interior of the colon, through this incision a No. 12 red rubber catheter is passed and the purse-string suture is tied round it. In order to hold the catheter in position, it is then transfixed by a needle carrying one of the ends of the tied suture, this end being knotted to the other end of the tied suture. When considered necessary administration of saline can be at once begun through the catheter before the perineal portion of the operation is commenced, though, as a general rule, Mr. Handley does not consider such a procedure to be called for, but when the patient is back in bed the catheter should be connected to a reservoir preferably of the "thermos" type containing saline at a temperature of about 170° F., and arranged for a delivery of about half a pint an hour. Should pain be caused owing to distension of the colon by fluid, the catheter must be disconnected from the reservoir and made to act as a flatus tube. Mr. Handley pointed out that it was usually desirable to keep up the administration of saline for, at least, forty-eight hours, possibly longer, with an interval of one hour in every four during which the catheter is allowed to discharge flatus. By this means, he said, the delayed shock, which so frequently comes on after the operation, would not occur. Mr. Handley claims very definitely and precisely that the employment of this method will reduce the mortality of the operation to half its present amount. His mortality up to the present has been 11 per cent. (1 case in 9), which he thinks a great improvement on the usually accepted one of about 25 per cent. Moreover, in his case that died, the fatal result followed intestinal obstruction. Three of his cases were males.

IN connection with the posts of Medical Officer on the staff of the National Health Insurance Commission (England), for which applications were recently invited, it is announced that the following have been appointed:—Dr. Edward William Adams, of Sheffield; Dr. James Pearse, of Trowbridge; Dr. William Vernon Shaw, of Malton and Norton (Yorks); and Dr. Barbara Martin Cunningham, of Manchester.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, JANUARY 8TH, 1914.

The President, MR. J. CHARTERS SYMONDS, in the Chair.

EXHIBITION OF CLINICAL CASES.

DR. H. D. ROLLESTON and Mr. E. G. BOYD showed a case of Addison's disease in a boy, with calcification of the adrenals. The patient, æt. 12¾, was bright, intelligent and fair-skinned until about the end of October, 1913, when his skin was noticed to be brown; this was at first attributed to dirt, and an attempt was made to wash it off. When this attempt failed it was thought to be due to his habit of drinking vinegar. Synchronously with his change in colour he lost all his energy, was inclined to sleep all day, very easily got tired, had a cough at night and nocturnal enuresis. There had not been any gastro-intestinal disturbance or fainting attacks. Except for chicken-pox some years ago the patient had not had any illnesses. An uncle and a brother were said to have had tuberculosis. On admission to hospital the boy had a somewhat lifeless, sleepy, sunken-eyed appearance and a general bronzing of the skin, especially around the nipples and pudenda. There was a pigmented scar in the left groin, and the back and abdomen showed a few scattered spots of pigmentation. There was no buccal pigmentation. There were no signs of pulmonary or spinal tuberculosis, and von Pirquet's reaction was negative. The systolic blood-pressure in the arms varied between 74 and 84 mm. Hg. There was no valvular disease of the heart. There was no dulness behind the manubrium sterni. Dr. Stanley Melville reported that a skiagram showed very definite calcareous particles in the region of the last rib and suprarenal body on the right side, less definite on the left side. The heart was small and vertical. There were discrete and dense opacities at the hila of the lungs, suggesting calcified nodules. The movements of the diaphragm were feeble, but the expansion and translucency of the apices normal. A blood count showed some polycythæmia, and an increase in white cells to 23,000 per c.mm.

Dr. ROLLESTON said that a high lymphocyte count had been thought to indicate concomitant lymphatism, and therefore to be an ominous sign. An increased number of red blood corpuscles was occasionally seen in Addison's disease, and various explanations had been offered. It had been thought to be due to concentration of the blood from vomiting or diarrhœa, neither of which occurred in this case. A specific action of tuberculous toxin had been invoked, and G. R. Ward had described the process as compensatory, and argued that adrenal insufficiency gave rise to circulatory stasis, which, in its turn, caused concentration of the blood and actual increased blood formation. The treatment which was being adopted was rest in bed and adrenalin chloride solution (1 in 1,000), 10 minims in water three or four times daily by the mouth.

Mr. SYDNEY BOYD showed a case of splenectomy for chronic acquired acholuric jaundice with splenomegaly. It was that of a man, æt. 22. The illness began in August, 1909, with lassitude, loss of appetite, indigestion, with occasional vomiting, especially after fatty foods, frontal headache, giddiness (especially on stooping) and slight icteric discoloration of the conjunctivæ and skin. Jaundice had persisted more or less since the onset, and always became worse after exertion. The urine was dark in colour and the stools were said to be light-coloured. Eighteen months ago the patient was admitted into a hospital in London, when the gall-bladder was explored and drained, with a negative result, the jaundice persisting. He first came under Mr. Boyd's observation in August, 1913, and was found to be a fairly well developed and well nourished young man. There was slight icteric tinging of the skin and conjunctivæ. The spleen was enlarged, extending two fingers' breadths below the costal margin. The liver edge could be felt just below the right costal arch and was rather firmer than normal. The other viscera were healthy, and the motions were of normal colour; the urine dark reddish-brown in colour, specific gravity 1015, acid, contained an occasional trace of albumin, no sugar, blood, or bile. The red blood cells numbered 4,200,000 per cubic millimetre, white cells 5,900, hæmoglobin 80 per cent., colour index 1.05. A week later the blood was examined by Dr. S. H. Browning, who reported as follows: "Total reds, not done; hæmoglobin, 96 per cent.; white cells, differential count (500 counted)—polymorphonuclears, 70 per cent.; lymphocytes, 28 per cent; large mononuclears, 1.2 per cent.; eosinophiles, 0.8 per cent.; mast cells, 0. From the appearance of the films there was some polymorpho-leucocytosis, the red cells varied considerably in size; there was some polychromatic staining. No normoblasts were seen. Some poikilocytosis. Films stained by Pappenheim's method showed granules in some red cells and some slight reticulation. The blood serum was quite greenish-yellow and gave all the reactions for bile pigment. The blood, unfortunately, underwent auto-hæmolysis before it was spectroscoped. The relation between serum and clot was very abnormal, about 7½ c.c. of serum in 10 c.c. of blood. Wassermann's reaction was positive. There was a very slight increase of fragility of the red cells. The patient was kept under observation in bed for four weeks. Jaundice was found to vary from day to day, and with each exacerbation he became drowsy and complained of headache and general malaise. A slight attack of tonsillitis lasting a few days caused some elevation of temperature, which was otherwise subnormal. *Operation.*—A preliminary hypodermic injection of morphine, scopolamine, and atropine was given. Inhalation anæsthesia by open ether was employed. Splenectomy was performed through a vertical incision near the outer edge of the left rectus. The spleen was delivered out of the wound, there being no adhesions to the diaphragm. The gastrosplenic omentum was divided close to the spleen between several pairs of forceps and ligatured. The splenic vessels between the two layers of the lieno-renal ligament were then similarly treated, being divided also close to the spleen. The wound was closed in layers without drainage. There was hardly any shock, very little vomiting, and no hæmatemesis followed. Convalescence was rapid. On the third day after the operation the jaundice was noticed to be very much less; at the end of a week the sclerotics had lost their icteric tinge and the urine was normal in colour. The patient expressed himself as feeling very much better, having lost his headache and drowsiness and digesting his food well. A second report on the blood was made by Dr. Browning one month after splenectomy: The Wassermann reaction was now negative, and Dr. Browning had little doubt that the former positive reaction was due to the excess of bile in the blood serum. The fragility of the red corpuscles was as before, practically normal. The blood had not hæmolysed of its own accord. Hæmoglobin, 100 per cent. Differential count normal. Character of blood cells normal. The blood seemed normal. Dr. A. G. Gibson reported on half the spleen sent preserved: The external shape of the organ was normal, and the size about twice that of the adult spleen, its surface was slightly roughened, but the capsule was not definitely thickened. On section it was dark brown in colour, and the Malpighian bodies were marked though not increased in size or number. The trabeculæ could also be seen. Small darker points could be seen here and there and suggested thrombosis in the smaller vessels; some of the larger vessels were definitely thrombosed. Microscopically, the organ was highly cellular. Malpighian bodies were present, and the larger trabeculæ were thickened. Red and white clot could be seen in some of the larger veins. In the more cellular parts were numerous lymphoid channels lined by a simple but not always regular epithelium. General fibrosis was not marked. Everywhere in the

sections could be seen pigment granules, mostly extracellular. There were no hæmorrhages to be seen, either in the neighbourhood of the trabeculæ or in the pulp. In the walls of a few thickened arterioles, out of a large number examined, were several thin, long, unbranched threads appearing black when stained by Wheal and Chown's method; none of these, however, though suggestive of a parasitic invasion, could be found to possess any features which could be taken as proof that they were mycelial threads. Some of these threads had been found in the pulp.

Mr. BOYD remarked that the case was one of chronic acholuric jaundice, clearly of a hæmolytic nature, and in the absence of any family or congenital history it must be grouped under the "acquired" type. Of special interest were: (1) The (practically) normal fragility of the red cells in saline solution; (2) the remarkable changes in the blood which followed the operation, including the conversion of a positive Wassermann reaction into a negative one; (3) the futility of drainage of the gall-bladder in these cases; and (4) the immediate and beneficial effect of splenectomy.

Dr. F. SYLVAN showed a case of pulmonary tuberculosis after gymnasic treatment. The case had been shown at a previous meeting of the section, and was brought up again to show that improvement had been maintained.

Mr. HENRY CURTIS showed a case of successful excision of the shoulder performed by Sir John Erichsen fifty years ago. The man was aged 64½. In 1861, when aged 12, he suffered from an abscess behind the right shoulder, and was seen by the late Mr. Sidney Jones, Assistant Surgeon at St. Thomas's Hospital. Mr. Sidney Jones evacuated the pus and inserted a seton in the wound. The shoulder was painted with iodine and covered with gutta-percha, according to the man's account. After two days the shoulder became very bad, and the patient returned to St. Thomas's Hospital, where he was admitted under Mr. Simon. After one week, the hospital was closed, and he was discharged unoperated upon. The shoulder was then poulticed until it finally closed up. In 1863 the arm "fell to the side" owing to the extensive disease of the bones about the right shoulder-joint. The patient went to University College Hospital, where Sir John Erichsen excised the shoulder-joint, but told the patient "he would never be able to get his hand to his head." In January and July, 1885, some sinuses above the right axilla (? shoulder) were treated by Professor A. E. Barker and Sir Victor Horsley. When shown there were seen to be numerous depressed scars of healed sinuses in front of and behind the right shoulder-joint. The right upper arm was notably shortened compared with the left. The right hand could be readily brought round to touch the occiput. Skiagrams were exhibited.

Dr. BERNARD MYERS showed a case of osteitis deformans. This patient was aged 57. He came to the Western General Dispensary about a year ago for advice with regard to severe pains in the back and legs. It appeared that he had suffered from pains in various bones and joints for five years. The affected bones included the vertebræ, both femora, especially the left, both tibiæ and fibulæ, the right radius and ulna and the skull. The walk of the patient was suggestive of osteitis deformans. He had lost about four or five inches in height since his pains began. The head was bent forward, evidently on account of the usual dorso-cervical kyphosis of this complaint. There was very distinct thickening of the left femur, which also showed an outward and a forward curve. There was some thickening of the left tibia and, perhaps, the right radius and ulna. The clavicles seemed to be a little enlarged also. The peculiar feature of the case was the apparent want of increase in thickness of the cranial bones. He could wear the same hard hats now as formerly. He had arterio-sclerosis rather well marked. Pains in the præcordial region troubled him occasionally. The appetite was good, the bowels open daily. The speech was "stuttery" at times, the memory was fair, and he slept well. There was no similar case in his family. The diagnosis of osteitis deformans was supported by the X-ray photographs, the only difficulty being his skull and a rather prominent lower jaw. The latter suggested the possibility of the co-existence of Paget's disease with acromegaly, but an X-ray picture showed a normal sella turcica and nothing abnormal in the inferior maxilla. With regard to treatment, he had taken quinine, iodide of potassium, and nux vomica with no noticeable benefit. For the pain various liniments had been tried and, perhaps, had been of some use, but his greatest relief from pain had been obtained from salicylate of sodium, which he was still taking in conjunction with tonics.

MR. THOMAS H. KELLOCK showed a case of lipoma nasi. The patient was a man, aged about 77. About twelve years ago he first noticed that the end of his nose was getting larger, and it had steadily increased in size since, but he thought the growth had been more rapid during the last six months or so. There was now a tumour almost the size of a fist attached by a pedicle to the lower part of the nose. It showed the usual depressions at the points where the sebaceous glands opened; it could be seen that the alæ nasi were independently in a similar condition. The case was of further interest in that, when aged about 15, he sustained a serious accident, fracturing the left thigh and both bones of the same leg below the knee. He was taken to Guy's Hospital immediately after the accident, where an amputation was performed by Mr. Westwood. The operation was done without any anæsthetic, and took, according to the patient's account, about a quarter of an hour, and subsequently the fractured thigh was set. From his own account, the man seemed to have been an interested spectator of the operation, and remarked to the surgeon that "the bone was uncommonly tough." The operation appeared to have been performed by the circular method at "the seat of election," but the end of the fibula projected beyond that of the tibia.

Mr. GORDON TAYLOR showed a case of osteitis deformans; operation for fractured femur. The man, æt. 56, was admitted to the Middlesex Hospital in April, 1913, for a fracture of the middle of the shaft of the right femur. Attempts to secure proper apposition of the fragments by means of splints and extension were not successful, and in May an operation was performed by Mr. Kellock, and the fragments were fixed by means of a Lane's plate. Recovery was uneventful, and he was transferred from the wards to the out-patient department in July. Before leaving the wards he was discovered to be suffering from osteitis deformans. Both femora and tibiæ were bowed; the upper part of the spine was fixed in its bowed position; the clavicles were enlarged and the bones of the upper extremity were also slightly curved. There appeared to have been no change in the dimensions of the cranium. The condition did not appear to have influenced the union of the fracture in any way.

Dr. W. ESSEX WYNTER showed a case of congenital heart disease, probably pulmonary stenosis with incomplete ventricular septum. The man, æt. 26, suffered from pains in both elbows and knees at the end of September, 1913, this being the only occasion on which he could recall anything of the nature of a rheumatic attack. On account of the loud cardiac murmur he was kept in bed for several weeks and finally sent to hospital. The apex beat was just within the nipple line, and pulsation, with dulness on percussion, extended one inch to the right of the sternum. A loud systolic murmur could be heard over the præcordia, the point of maximum intensity being in the fourth space near the sternum. It was so loud that it could be heard for some distance radiating from this point, but was best conducted towards the left clavicle in the course of the pulmonary artery. It was inaudible in the carotids and posteriorly. The second sounds were distinct but not increased, and there was no diastolic murmur. The pulse was normal in character, neither small nor collapsing, and regular. Blood-pressure, 170 mm. of mercury. There was no enlargement of the liver, no œdema, nor any cyanosis except during rare attacks of cardiac disturbance, and there was no clubbing of the digits. The patient had always suffered from shortness of breath on exertion, was never able to play games, and could not perform any arduous

work. Blood count: Red cells, 6,512,000; white cells, 6,400; hæmoglobin, 100 per cent.; index, 0.8. The X-ray screen disclosed enlargement of the right ventricle and limited bulging of the conus arteriosus to the left.

Dr. W. ESSEX WYNTER also showed a case of patent ductus arteriosus. The woman, æt. 35, was admitted in December, 1913, for hysterectomy on account of uterine fibroids. This had been considered twice during the past two years, but operation was thought inadmissable on account of the heart condition. The same doubt arose again, but the view that the murmur was due to a patent ductus having been arrived at, no objection remained either to the operation or anæsthetic. Total hysterectomy was performed by Sir John Bland Sutton. No trouble was experienced with the anæsthetic, the patient bearing the operation well and making a very rapid recovery. The patient had scarlet fever at the age of 7. "Cardiac weakness" had been noticed for five years since the third and youngest child was born. With the dysmenorrhœa which occurred during that time there were often associated pseudo-anginal attacks. A loud systolic murmur was heard in the third left intercostal space, accompanied by a thrill. There were no appreciable cardiac changes or enlargement. The temperature was normal and there was no dyspnœa even on exertion. She played hockey and cricket in girlhood, and activity had not been restricted by the heart condition. No secondary changes, such as enlarged liver or œdema, had occurred. By the X-ray screen the heart appeared normal in size and position, but there was bulging of the pulmonary artery above the heart shadow.

Also a case of chronic lymphatic obstruction. The man, æt. 44, had suffered for eleven years from the condition, consisting of tense œdema of hands and wrist with progressive enlargement of the head and lower jaw and attacks of dyspnœa. In 1906 amputation of the left forearm was performed in Buenos Ayres, as the tense skin ruptured and sloughed. The remaining hand is almost globular owing to the swelling. There was some power of movement in the wrist, but little or none in the hand and fingers when the swelling was great. Sensation was lost as far as the elbow. There were some small superficial sloughs on the back of the hand. Appreciation of touch, pain and temperature were lost here and up to a fairly definite line above the elbow. The head appeared to be increasing in size, as larger-sized hats were required, and the extension of the lower jaw with loss of teeth interfered with mastication. Headaches occurred from time to time, accompanied by nausea and also attacks of hæmaturia, when clots appeared in the urine for three days at a time. Within a few months of the commencement of the illness notable enlargement of the glands in the axillæ and above the left clavicle occurred and had recurred on four occasions, the swelling attaining the size of a golf ball and lasting a week. Urine, specific gravity 1026, deep yellow, no albumin or sugar, no deposit.

The patient had enteric fever and empyema at the age of 8. The thoracic and abdominal organs appear normal, and there was no abnormality about the trunk or lower extremities. The mother and five brothers and sisters were living and well. An X-ray screen examination showed some light shadows in the region of the bronchial glands on each side of the vertebral column, but no massive enlargement or growth. The sella turcica did not appear enlarged, but there was some increase in size and density of the hand bones.

Dr. C. R. BOX showed a case of hypertrophy of the bladder, accompanied by polyuria and polydipsia, in a boy, æt. 7.

Mr. BERNARD ROTH show a boy, æt. 9, with a fusiform swelling of the shaft of the left humerus.

DR. TEMPEST ANDERSON, M.D., D.Sc., F.R.G.S., F.G.S., F.L.S., of 17 Stonegate, York, a former Vice-President of the British Association, an authority on volcanoes, who died at sea on August 26th last, aged 66 years, left estate of the value £97,365.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 10th, 1914.

EPIDIDYMITIS.

ARGYROL, which succeeds so well in the acute stage of gonorrhœa, is equally efficacious in the treatment of epididymitis.

Argyrol, 5 dr.
Axunge, 10 dr.

This ointment is rubbed in gently and persistently over the inflamed organ twice a day, and followed by a compressive bandage. Towards the third or fourth day, when the inflammatory symptoms have subsided, the application need be made but once a day.

Rest in bed is only necessary during the acute period, which scarcely exceeds 24 hours, the temperature becoming almost normal after the second application. Pain disappears, and the patient is surprised at the relief so quickly obtained, and can resume his occupation provided he wears a suspensory bandage.

The treatment ceases by the sixth day, when the organ is no longer painful to pressure. One of the most characteristic effects of the treatment is the rapid disappearance of induration, generally so persisting; it would seem also that the physiological integrity of the epididyme is re-estblished.

During the treatment injections of argyrol (1-100) will be contiued in the urethra.

The same treatment is efficacious in orchitis produced by catheterism in prostatic patients.

OPHTHALMIC ZONA.

The eruption of ophthalmic zona, like all zonas, is exclusively localised to one side of the head; its danger resides in possible complications as regards the organ of vision: conjunctivitis, keratitis, iritis, tedious and rebellious to treatment. The cutaneous lesions get well very quickly, but those of the eyeball, if not carefully treated, may become the source of grave troubles, even with loss of the organ.

Consequently the eye should be examined each day, so as to detect any complication. Conjunctivitis will be treated with instillations of

Argyrol, 8 gr.
Water, 3 dr.

If keratitis is observed, the same solution is employed, and, once a day, one or two drops of a one per cent. solution of atropine to prevent iritis, which frequently accompanies keratitis.

On the cutaneous lesions an antiseptic powder is applied—

Oxide of zinc, 3 dr.
Talc, 3 dr.
Essence of geranium, 5 drops.

ERYTHRASMA.

Inguinal intertrigo is a cutaneous affection, having for seat the internal surface of the thigh, immediately below the inguinal fold. It is observed generally in the adult, more frequently in men, and on the left side at the point where the scrotum touches the thigh, in the form of red patches more or less humid.

This dermatosis, which provokes severe itching, is due to the presence of microsporon minutissimum, and is quite amenable to the following treatment:—

Tincture of iodine, 5 gr.
Hoffman's anodyne, 6 oz.

applied daily by means of a brush, and followed by

Calomel, 6 gr.
Tannin, 6 gr.
Vaseline 1 oz.

The treatment lasts eight or ten days, but relapses are possible.

GERMANY.

Berlin, Jan. 10th, 1914.

AT the Gynæcologische Gesellschaft, Hr. Schäfer spoke on

PUERPERAL INVERSION OF THE UTERUS.

He said it was fortunately a comparatively rare occurrence. In a total of 38,000 labours at the patients' own homes, it only occurred three times. It was most probable that the cause was expression of the placenta when the uterus was in a flaccid condition. This was in opposition to the view of Dührssen, which was that it was caused by traction on the cord. Of five cases met with four died. Among the cases recorded in the literature of the subject the mortality was 20 per cent. Death was due to hæmorrhage or to shock. It was difficult to say which of these was in the foreground. The speaker himself was of opinion that hæmorrhage was the chief cause. Incomplete inversion was easy to replace, the uterus was then to be packed and ergot given; at the inversion ring the uterus was to be provided with a ligature. It was better, however, to apply a Schleich (indiarubber) bandage at once, so that time might be gained for disinfection. Tampons, however, ought always to be applied. It was a very good procedure to cover the uterus with gauze, and pack this in along with the replaced uterus.

In the discussion that took place, Hr. Jolly said it was remarkable that inversion did not take place more frequently than it did. The cause might lie in dilatation and relaxation of the os internum. Placenta accreta was frequently a cause, there must be some morbid condition of the uterine musculature as a precedent condition. He related particulars of a case observed by himself, and showed a microscopical preparation that demonstrated a direct connection of the placenta with the muscular tissue. He was of opinion that hæmorrhage was the sole cause of death. If inversion occurred repeatedly in the same case, a colporynteur should be inserted.

Hr. Franz had seen two cases following expression in which replacement took place without any difficulty. He thought the cause was paralysis of the placental site.

Hr. Bumm said that the trend of the discussion was to the effect that there was a precedent predisposing cause. In two cases that came under his notice he could only recognise a mechanical cause; he believed it was the way in which the expression was carried out.

At the Verein für Innere Medizin und Kinderheilkunde, Hr. Lederman discussed

CONGENITAL SYPHILIS AND SERODIAGNOSIS.

He first showed a child, æt. 7½, with hereditary syphilis, who had a saddle nose and linear cicatrices near the mouth. He then went on to say that he had made use of the Wassermann test in 144 infants who were suffering from hereditary syphilis. Failure took place only in three cases, in which there was no syphilis: one case of otitis media with influenza, one with pneumonia, and one of furunculous sepsis. In infants with manifest syphilis the reaction was always positive. Occasionally it was negative immediately after birth, but it became positive later on. Twice he had observed cases where the mothers were clinically healthy and had syphilitic infants that had not undergone any treatment where the Wassermann test was negative. Syphilitic children had to be followed up for years with the serological tests. Occasionally it happened that serious complications did not arrive until later in life.

Hr. Ritter spoke on

THE NATURE AND TREATMENT OF WHOOPING COUGH.

He described and showed the different micro-organisms associated with the disease. In regard to microscopic examinations of sputum, most observers had been in agreement, differences did not begin until cultivations were begun. The microbes described by Bordet and Gengou were the most frequently met with, but they were not present in relapses. The bacilli discovered by the speaker himself, however, were always present.

Hr. Buttermilch spoke on the treatment of the disease. He had treated 66 cases in two years, with 12 deaths. The value of specific remedies could only be judged in severe cases. Not one of the remedies so much recommended had proved to be of any value. He laid the chief stress on proper nourishment, and especially in the cases in which any disturbances of nutrition were present, quiet surroundings and fresh air. He only rarely resorted to narcotics (bromoform).

Hr. Meyer, in contrast to the previous speaker, said he had seen good results in Berlin, where the fresh air cure could not be carried out in the so-called box treatment, in which the air was shut out; there was nothing contradictory in this: the one treatment was one of increasing the resistance, the other one of diminishing the sources of irritation.

Hr. Croner did not believe in one cause of the disease only. There were cases that were on a nervous foundation, others depended on infection. Bacilli only played a secondary *rôle*. Possibly some amœbic organisms were to be considered. Cases with complications should not have narcotics. He had seen "right good" results with thymipin.

Hr. Buttermilch thought thymipin was useless Where there were convulsions lumbar puncture had done good.

AUSTRIA.

Vienna, Jan. 10th, 1914.

AT the recent meeting of the K.k. Gesellschaft der Aerzte in Vienna, Dr. J. Schnitzler exhibited a patient who presented a rare form and localisation of neoplastic metastasis. There was situated over the arch of the right shoulder a fluctuating painless tumour, of the size of an apple, and of flattish rounded shape; which was fixedly adherent to the underlying tissues, and covered with skin that was apparently unaltered. The tumour might, indeed, be taken for a cold abscess. A significant feature, however, was that the tumour was surrounded by a very firm wall. The clinical history and further examination proved that they were dealing with a metastasis of a carcinoma of the penis which had been operated on a year before. A similar metastatic growth had also formed on the sacrum.

Dr. E. Ruttin exhibited a patient from the Urbantschitsch Clinic: a young man who had had a strong acid dashed over him in the course of a pogrom in Russia. In addition to extensive burns over the face, complete atresia of the auditory canal of one side resulted. The range of audition was reduced to half on the affected side; and, as the posterior membranocartilaginous portion of the auditory canal could hardly be re-habilitated without extensive removal of the osseous wall, and there was no indication in front for interfering with the bone, Dr. Ruttin was obliged to devise a special form of procedure. Accordingly, after cutting through the cartilage of the ear, he completely removed the posterior portion of the membranocartilaginous wall of the auditory canal, and brought in from behind, through the opening thus formed, a pedunculated skin flap, which he adjusted to the posterior wall of the auditory canal. The pedicle was divided subsequently. The result was a neat and widely open auditory canal, with normal range of hearing.

Dr. W. Marschik exhibited two anatomical preparations: (1) A papillary carcinoma of the branch of the right bronchus which passed to the upper lobe of the lung, that occurred in a woman, æt. 49. The preparation showed that the tumour, as is usually observed in case of bronchial neoplasms, was mainly located on the bronchial tree of the upper lobe, the course of the branches of which it followed by infiltration, while it extended but a very little way into the surrounding pulmonary tissues. The main bronchus itself, and the pulmonary tissues of both the other lobes had remained perfectly intact. (2) A carcinoma of the hypopharynx, from a man, æt. 58, which had been subjected to radium radiations. The condition at the time of commencing the treatment was: recurring paralysis on the left side, with great swelling, and fixation on the left side of the larynx. The left recessus pyriformis was obliterated by a destructive tumour, which extend to the upper extremity of the œsophagus, as was shown by œso-

phagoscopic examination. On the side of the neck, a hard, rope-like glandular tumour could be felt, which reached to the mastoid process. On account of the weakly condition of the patient, the idea of a radical operation could not be entertained, and the radium treatment was adopted; but, as was Dr. Marschick's usual practice, the metastatic growths in the lymphatic glands were extirpated beforehand. A small portion had, however, to be isolated at the upper end, near the mastoid process, as it was apparently adherent to the coat of the internal carotid artery. By this operation the tumour of the hypopharynx was simultaneously exposed and drained, so that a direct cross-fire of radiations was made possible. The radium was directed to both the tumour and the glandular fragment, and altogether about 3,000m.g./St. were applied. In the course of a few weeks from the commencement of the radiation treatment, a conspicuous effect had been produced; and 14 days before the end, scarcely anything pathological could be detected with the laryngeal mirror—apart from the recurrent paralysis. Complete disappearance of the tumour was also shown by œsophagoscopy, while, above all, there was no ulceration of any kind. Immediately after this procedure of œsophagoscopy, the patient was attacked with fever, and signs and symptoms of gangrene of the lower lobe of the lung of that side proceeded to develop. The patient succumbed to this complication. The autopsy merely displayed gangrene of the lung, with great probability of its cause by infarction from a small parietal thrombus of the jugular vein of the right side. It is not impossible that the œsophagoscopy, with its influence on the general environment in way of reflex coughing and choking, and consequent oscillations of the blood-pressure, was the immediate determining force which produced the embolism. The preparation showed a thoroughly astonishing cure of the destructive and extensive tumour of the mucous membrane by the radium treatment—so complete, indeed, that the pathologist who made the *post-mortem* examination could not refrain at first from expressing some doubt as to the accuracy of Dr. Marschik's autopsy *in vivo*. In fact the mucous membrane of the parts in question not only presented no tumour, it presented no coloration or macroscopic appearance which contrasted in any way with that of the surrounding parts. The sole surviving trace of the original tumour was found, after a good deal of searching, in the shape of a small warty excrescence of the anterior aspect of the mucous lining of the upper extremity of the œsophagus.

HUNGARY.

Budapest, Jan. 10th, 1914.

THE ÆTIOLOGY OF CANCER IN INSURANCE CASES.

DR. RADVANYI reviews twenty cases in which cancer developed at the point of a trauma, and a claim was made for industrial insurance money. In only a few of the cases (four) was a causal connection probable. In one case the trauma caused a fracture of the shoulder at a point which proved to be already the site of a sarcoma, and the brachial bone was exarticulated. The trauma in this case revealed the malignant disease long before it would otherwise have been detected. In the case of a man of 36, previously healthy until a block of ice fell against the lumbar region, a sarcoma gradually developed in the right kidney, and the kidney was removed the fourth month, but the patient succumbed to metastasis nine months after the accident. An insurance indemnity was awarded in this case, the death being regarded as the result of the injury, but this was accepted in only one of the other cases.

THE TREATMENT OF MUSCULAR RHEUMATISM WITH MASSAGE.

Dr. Andriska reviews the Hungarian literature on this subject in the last five years, and reports excellent results from moderate massage. The rheumatic affection is localised both in muscle and fibrous tissue, the main symptoms being pain, tenderness and functional disturbances. They differ from nervous disturbances in their hindrance to movements of the part affected, and in the fact that the rheumatic pains are most severe in the morning or after rest and are improved by work, contrary to what is observed in neuritis. The rheumatic pain in the head radiates from the back of the neck upward, while the neurasthenic headache spreads sideways over to the forehead, back of the eyes, and thence upward to the top of the head. The rheumatic pains also occur only with certain movements, while the nervous accompany any movement. The lumps and nodules felt by some in the muscles, the seat of the rheumatism, he thinks are merely the natural contraction of the muscle under the influence of the palpation. Local tenderness is not a reliable means of differentiating between nervous and rheumatic affections, he declares, as there are so many points which are sensitive in everyone. Rest is useful in nervous and periosteal affections, while the muscular profit by a certain amount of exercise.

TREATMENT OF ENURESIS.

Klotz, in Germany, has noticed that children inclined to enuresis sleep unusually heavily, and even when awakened in the night the bladder is liable to empty itself spontaneously before the child is fully aroused. In institutions the person on duty in the night can systematically wake the child and thus forestall enuresis; but in the family the better plan, says Dr. Edward Grosz, of Budapest, is to prevent such heavy sleep by having the child take a nap morning and afternoon for two hours. This is particularly important for lively, active children, and it is this class who are so exhausted at night that their sleep is abnormally heavy. By this means, with a little training, the children soon learn to wake and attend to nature spontaneously. He has another method for less nervous children which has been found very effectual, both in Klotz's and in his own cases—inducing a psychic shock, which seems to cure the tendency to enuresis. The child sits naked on a stool, the seat of which is cut out and has an arrangement below by which a strong jet of cold water can be turned against the anal and genital region. A single application of this method generally sufficed. If it has to be repeated he alternates the cold with warm water. He has found this douche a valuable aid in institutional care of enuresis. In treatment of anal incontinence, he trains the child to systematic defæcation by the regular use of glycerin suppositories, twice a day, soon substituting cocoa-butter suppositories, and omitting both at the earliest moment when defæcation proceeds without them, after rhythmic functioning of the bowels has been secured. In inflammation of the bladder and kidney pelvis, with acid urine, he has long been using potassium citrate with excellent results. He gives to infants from 0.5 to 1 gm. (7.5 to 15 grains) two or three times a day, increasing the dosage if the urine has not become alkaline by the second or third day. Larger children require larger doses to bring an alkaline reaction at once. The cure is generally complete in three or four weeks. This vegetable alkali, he says, is non-toxic and more effectual than sodium bicarbonate.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH.

SUBSCRIPTIONS TO MEDICAL CHARITIES BY INSURANCE COMMITTEES.

IN connection with the appeal made by the managers of the Edinburgh Infirmary for financial support by approved societies and insurance committees, it may be stated regulations have been issued by the Scottish Insurance Commissioners providing that expenditure on hospitals or nursing societies, under Section 21 of the Act, shall be treated as expenditure on sickness benefit. Such subscriptions must come from the ordinary benefit fund of the society, and no margin has been provided in this fund for the special purpose of meeting the aforesaid expenditure. Therefore,

each society must decide in how far judicious expenditure in this direction would promote recovery from sickness, and thus relieve the ordinary sick benefit demands. As such relief might not be at once experienced, societies are advised not to incur any liabilities under this head unless they have actually saved money. Expenditure on nurses for the purpose of visiting and nursing insured members can only be treated as sick benefit under Section 21 if the persons are appointed for actual sick nursing duties. Payment of visitors whose duties are purely administrative must be charged to the administrative account. As the payment of midwives is on a different footing, inasmuch as maternity benefit may be afforded otherwise than in cash, a society is entitled to provide duly certified midwives for its members, and to charge their salaries to the maternity benefit account.

UNIVERSITY OF EDINBURGH: WORK OF THE YEAR 1913.

The total number of matriculated students was 3,261, including 549 women. Of these, 1,200 were arts students, 412 science students, 254 law students, 1,315 medical students, and 20 music students. Of the students of medicine, 43 per cent. were Scottish, about 18 per cent. English, about 23 per cent. Colonial; 72 were from Ireland, 102 from India, and 47 from foreign centres. The percentage of non-Scottish students is thus well maintained, and that of Colonials is the highest ever reached, the increase being especially marked in the students from South Africa. The number of women attending extra-mural lectures with a view to graduating in medicine was 79. The medical degrees conferred were as follows:—M.B., Ch.B., 177; M.D., 80; M.Ch., 3. The Diploma of Tropical Medicine was granted to 2 candidates; of Psychiatry to 3. Two new chairs have been founded during the year—The Robert Irvine Chair of Bacteriology, and the Moncrieff Arnott Chair of Clinical Medicine, to which Professor Ritchie and Professor Russell have been appointed. The new teaching arrangements in connection with clinical medicine have involved a large increase in the number of senior University lecturers, for the ordinary physicians and surgeons of the Infirmary now take that rank. A lectureship has been instituted on the physiology of the nervous system, and Dr. Ninian Bruce (a son of the late Dr. Alexander Bruce) has been appointed lecturer. Among the matters of general interest are the appointment of M. Henri Bergson as Gifford Lecturer for 1914, and Sir William Ramsay, D.C.L., as his successor in 1915-17. There have been many changes in the personnel of the University since the last report was issued. Professor Macgregor died last May; he succeeded Professor Tait in the Chair of Natural Philosophy in 1901. The vacancy has been filled by the appointment of Professor Barkla, F.R.S., University of London. Professor Harvey Littlejohn succeeds Sir Thomas Fraser as the Assessor of the Senatus on the University Court. Professor Geikie is succeeded by Professor Hudson Beare as Dean of the Faculty of Science. Among the medical lectureships the following changes may also be noted:—Dr. Sym succeeds Dr. Mackay as Lecturer on Ophthalmology; and Dr. John Thomson succeeds Dr. Dunlop as Lecturer on Diseases of Children.

As to new buildings in progress, the new agricultural department in George Square is well under way, and during the year there was opened a new "Habitation" for Indian Students. The University has also received a number of benefactions in the shape of money and other gifts, chief among which are a further sum from the trustees of the late Mr. James Clason Harvie towards the formation of a Chair of French and German; a portrait of Sir William Turner by Sir James Guthrie, R.S.A.; the private residence in Edinburgh of the late Rt. Hon. Wm. McEwan, presented by his daughter; and many others.

GLASGOW.

THE DIVISION OF UNALLOCATED FUNDS.

IN regard to the resolution of Glasgow Burgh Insurance Committee to divide the unallocated insured among those doctors who have a smaller list than 1,500, dissatisfaction has been expressed by those who would thus be excluded from participation in the division, and it seems to us that there is reason for this dissatisfaction. The arrangement proposed by the Committee has therefore been upset. Further, instead of paying at the rate of seven shillings per annum for each unallocated insured person, the Committee intended to pay only somewhere about five shillings. This is another matter requiring to be put right. Unless this is done, it is obvious that the medical men who have been on the panel during the year now closing will not receive among them the sum they were promised.

In connection with the circular recently issued by the Board constituted under the Highlands and Islands (Medical Service) Grant Act, 1913, a meeting has been held at Portree, representative of Skye. It was unanimously agreed that a committee representative of the whole island should be appointed to make the suggestions called for by the Board, and that the committee should act independently of the District Committee of the County Council, and deal directly with the Medical Service Board. The composition of the committee was arranged, and provides for delegates from various bodies, including two delegates from the medical practitioners. Meetings on the same subject have also been held in other parts of the Highlands.

A meeting of medical practitioners on the panel for the County of Lanark was held in Glasgow on 7th inst. Under an agreement come to between the Insurance Committee for the county and the practitioners on the panel, it had been provided that a deduction of twopence per insured person should be made for the purpose of constituting a special mileage fund for the county, and that the local medical committee should arrange the payments to be made for mileage to rural practitioners. A grant had now been received from the Treasury, it was stated at the meeting, which would largely meet the claims of the rural practitioners. Under these circumstances an arrangement for the disposal of the special mileage fund, suggested by the Insurance Committee, was, on the motion of Dr. McPherson, seconded by Mr. Millar, Bishopbriggs, agreed to.

UNIVERSITY OF GLASGOW—WORK OF THE YEAR 1913.

Preceptor James McFarlane, Assessor for Glasgow Town Council in Glasgow University Court, in demitting office last week, referred to the progress which the University had made in the four years representing his period of office. Of its present Professors, no fewer than seven were Fellows of the Royal Society of Great Britain. During recent years there had been special development on the medical side, and the degrees of the University now ranked among the highest in the medical world. Nearly 25 per cent. of the students were women—a proportion much greater than in Edinburgh, and that to a certain extent was a disquieting feature. This "disquieting feature" to which Preceptor McFarlane alluded may probably be attributed largely to the position of Queen Margaret College as part of Glasgow University, in contrast to the extra-mural position of the Edinburgh School of Medicine for Women.

LEGACIES TO GLASGOW INFIRMARIES.

The executors of the late Mr. Edward Davis have now distributed the balance of the residue of his estate among the three Glasgow infirmaries as follows: Royal £1,000; Western, £1,000; Victoria, £700. These sums are in addition to the amounts that have already been paid to these institutions from the same source. The total amount that has been paid from the Edward Davis Bequest to Scottish general hospitals in £55,800, free of legacy duty.

BELFAST.

THE Belfast panel practitioners have a grievance against the Insurance Commissioners, which was discussed at a meeting of the Local Medical Committee, held on the 2nd inst. The facts are as follows:—In April, 1913, by order of the Irish National Health Insurance Commission, a certification panel was set up in Belfast, 123 local practitioners signing the

necessary agreement. The conditions of service were: (1) Remuneration at the rate of 9d. per caput; (2) payment quarterly; (3) this agreement to end on 14th January, 1914. As to the first of these conditions, the Commission issued two agreement forms. The first of these promised remuneration at the rate of 9d. per caput until the expiry of this agreement on the 14th January, 1914, and the second agreement said the remuneration would be at the rate of 9d. per caput per annum until that date.

As the case stands at present, no payments have yet been made, nor has the Commission offered any explanation for the delay. It is now within a few days of the end of the term, and as they have neither been paid for the work done nor any arrangement been made for the future, the practitioners interested, and, indeed, the whole profession, would appear to have a very just cause for complaint. Indeed, if an explanation is not forthcoming, the whole matter is likely to be placed before the public in the lay Press.

The medical profession has very frequently during the past year been adversely criticised both by the public and by the Commission, but treatment such as this cannot be considered fair or reasonable, or conducive to the smooth working of the Insurance Act.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE QUESTION OF REFORM OF THE B.M.A.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I am afraid your able and courteous correspondent, Dr. S. J. Ross, and I must agree to differ with respect to the B.M.A. *Journal*, for I remain convinced that a plebiscite of members would result in a large majority in favour of a great reduction in the size of the paper. My own case is, I think, typical of a large number. I, evidently like Dr. Ross, am a constant reader of your paper besides the *Journal*. Then I often like to read a good book on some medical or scientific subject. I recognise the danger of becoming narrow-minded and shoppy, the bane of most professional men, and feel bound to keep up with contemporary history through a daily and weekly leading London paper, and I am obliged to look through a local paper to see what the authorities with which I am in contact are doing. Further, to prevent intellectual narrowness, or perhaps mainly because I love good literature, I always have in hand either an old classic or a new book of first-rate quality, including on occasions a taste of the cream of current fiction. With all these calls for mental exercise it would be a relief to find all medical periodical literature as concise as the MEDICAL PRESS, and it is for this personal reason, as well as for the financial relief to the Association, that I advocate the cutting down of its *Journal*. In previous letters during the past few years, I have advocated in your pages other changes which I believe would prove of great advantage to the Association. It has all along been my opinion that the Association ought to assume the constitution of a trades union. It need not change its title in doing so; it would merely acquire a legal status, in which its powers would be vastly increased. Trades unionism is, however, not necessarily opprobrious; it is so only when it is used for purely egoistic purposes, without regard to the welfare of the community and the State. So long as our calling is followed by men the great majority of whom are imbued with professional spirit, it is certain they will never adopt the methods of the sordid huckster, or of the degraded trades unionist. What the profession needs is an organisation ensuring the combined action of the vast mass of members. If such an organisation had existed, we should have been able to dictate our own terms to the Government in the matter of National Insurance; we should be able now to command the attention of Parliament in the question of medical law reform—a question of far more importance to the public than to ourselves. In these and in every other direction in which our profession is brought into relation with the State an Association able to speak truly in one united voice would surely prove as valuable to our country as advantageous to ourselves.

I am, Sir, yours truly,

AN OBSCURE MEMBER.

January 10th, 1914.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have always been an enthusiatic supporter of the Association. I have, however, never stated that its administration is perfect. What I have persistently and consistently urged is that some practical and practicable scheme of reform be submitted to the Executive Committee for consideration. In the letter of "Tweuty Years a Member" a definite charge is made against the present executive. Now let your correspondent follow up his assertion by formulating his reasons for making such a statement. Let us have in black and white the errors committed, and let this be followed by suggestions which, if carried out, will prevent the repetition of such errors. Then we shall have taken a step forward. I am perfectly open to conviction, if well-authenticated facts be adduced to prove your correspondent's statement. Though enthusiastic, I am not yet blind. It is after all unprofitable to have mere paper backers in a question of such vital importance as this is. Let your contributor obtain a following in his division, and prepare a resolution for the next divisional meeting, which could be, if adequately supported, sent to a Representative Meeting for consideration.

I am, Sir, yours truly,

S. J. ROSS.

Monkhams, Bedford,
January 9th, 1914.

OBITUARY.

DR. CUTHBERT J. CLIBBORN.

IT is with much regret we announce the death of Dr. Cuthbert J. Clibborn, who was for many years a medical inspector of the Local Government Board of Ireland. He came of a respected Quaker family resident for some centuries in the Co. Westmeath. Born 67 years ago, Dr. Clibborn was educated at Trinity College, where he graduated as B.A. and M.B., and subsequently he was in practice in County Wicklow. Seventeen years ago he was appointed an inspector under the Local Government Board, and was made responsible for the supervision of the whole of Ulster. During his tenure of office he was active in promoting public health work in the northern province, and he was much respected both by the medical profession and the members of the various public bodies with whom his official duties brought him into touch. He retired three years ago, and since then has resided in his native county.

DR. JAMES C. FERGUSON, BELFAST.

WE regret to announce the death of Dr. James C. Ferguson, of Glenfield Place, Ormeau Road, Belfast, which took place with startling suddenness on the 6th inst. The deceased, who was a dispensary medical officer under the Belfast Board of Guardians, had, in accordance with his usual custom, gone to his dispensary about 11 o'clock on the day of his death. While conversing with one of his colleagues he collapsed and almost immediately died, apparently from sudden heart failure. Dr. Ferguson's demise will be sincerely regretted by the medical men of Belfast and by a large circle of friends, for he was highly esteemed as a concientious and capable medical man who was always ready to assist in any deserving cause. His merits were highly appreciated by the Board of Guardians who, at a meeting which was held almost at the hour of his death, passed a resolution deploring their loss and the loss to the poor of the city. Dr. Ferguson was a native of Doagh, where his father had practised as a medical man. The

deceased, who was 58 years of age, was educated at Queen's College, Belfast, and took his degree in the Royal University of Ireland in 1884. In the following year he was appointed resident medical officer to the Belfast Workhouse, and in 1888 he was selected as one of the dispensary medical officers. He held this position to the day of his death. The deceased leaves a widow and two daughters, with whom the deepest sympathy will be felt in their bereavement.

DR. JOHN MEREDITH.

THE funeral of Dr. John Meredith, of Wellington, Somerset, which took place at that town on Saturday, afforded ample testimony to the high esteem in which the deceased gentleman was held, for there was a very large and representative attendance. Dr. Meredith, who had passed his 81st birthday, died quite suddenly on Wednesday while on a visit to his sister at Llandrindod Wells, after having left Wellington apparently in his usual robust health.

Dr. Meredith was one of the best known men in the county, and was one of its oldest medical practitioners, for he was registered on April 2nd, 1861, so that he had practised for the long period of 52 years, a like period to that of Dr. H. J. Alford, of Taunton.

He was a member of the Somerset County Council, Somerset Archæological Society, Taunton Cymmrodorion Society (he was born at Llanbadarn Fawr, near Aberystwyth), a Justice of the Peace for Somerset, and for many years medical officer to the Wellington Local Board of Health, and the Urban District Council, which succeeded it. A staunch supporter of the Liberal cause, he frequently spoke in a trenchant manner on the political platform.

As a young man Dr. Meredith saw many adventures, as he served as medical officer in British Guiana, and in India, where he witnessed a good deal of fighting in the Bhotan Campaign in 1865. Afterwards medical officer at Puri, Juggernaut, his duties there consisted of visiting about 200 plantations, and reporting on the conditions of the dwellings, etc., his instructions containing the sentence:—"Your duty is perpetual locomotion." Dr. Meredith, who had lived and practised at Wellington for nearly 40 years, was simply steeped in the legendary lore of his native land of Wales.

DR. HALL, MAYFIELD.

THE death of Dr. J. H. Hall, of Bankside, Mayfield, took place suddenly on Saturday, January 3rd. The deceased gentleman was speaking to a neighbour a few minutes before the sad event took place. Dr. Hall was an old resident in Mayfield, but had not practised for some years. Only as recently as Michaelmas he relinquished farming. He was held in the highest esteem in the neighbourhood. It will doubtless be recalled that Dr. Hall lost his son (who had assisted him in his practice) about seven years ago, suddenly from pneumonia. As a result of a memorial to this son the "Dr. John Hall" Fund was inaugurated.

REVIEWS OF BOOKS.

SCIATICA: A FRESH STUDY. (a)

THE construction of this book is rather singular, in that it is made up of two-fifths of appendices and, of the remainder, one-half quotations. Yet this is unquestionably a very personal work, the author having set out with the avowed intention of proving that sciatica is neither a neuralgia nor a neuritis, but is purely and simply a manifestation of hip disease.

Now, the reader's first impression is the necessity of defining what is meant by sciatica, because, in a general way, sciatica varies in severity from a "sore nerve," the sequel of gastronomic indulgence, to a pain-racking affection peculiarly refractory to treatment. Pain and tenderness in the course of the sciatic nerve, even if they only last a few days, constitute sciatica, but it would plainly be preposterous to suggest its dependence on disease of the hip-joint. The fact that it often subsides suddenly and completely negatives that theory. The same objection may be raised even in cases of medium severity, and this leaves us with the grave, persistent, refractory cases which are the bugbear of the therapeutist. Now it is quite possible that in many of these cases the pain and trophic disturbances are associated with concomitant changes in the head of the femur and the fibrous joint structures. We say "associated with" advisedly, because the latter may conceivably be secondary to the former, there being nothing in their early history to establish any claim to priority. We are quite prepared to concede that "sciatica" is sometimes merely symptomatic—in fact, the cases might well be grouped as "essential and symptomatic." After all, the trophic changes in muscle and articular structures are only what one might expect in connection with a disease like acute sciatica, which immobilises the parts for weeks and months at a time. Sciatica is fundamentally an arthritic manifestation, so that the periarticular structures are peculiarly vulnerable. The trophic changes moreover may be due partly to mechanical causes and partly to involvement of the muscular and articular branches of the nerve.

Dr. Bruce's notes and plates amply prove his contention in regard to certain cases, and afford irrefragable proof of the implication of the hip-joint, but they fail to establish the sequence of events. Just as some cases of brachial neuritis are associated with mischief in the shoulder-joint, so some cases of sciatica are accompanied by, possibly dependent upon, mischief in the hip-joint.

We cannot withhold our admiration for the painstaking thoroughness with which the author has gone into the matter in order to provide accurate data in support of his conclusions. This labour will not have been wasted if it leads us to examine the hip-joint carefully in every case of grave sciatica. There can be no question that too superficial an exploration is responsible for many errors of diagnosis. With regard to the treatment, that of "rheumatic arthritis" of the hip-joint is hardly more promising than that of obstinate sciatica. We must join issue with the author when he suggests that an error in diagnosis is likely to be fraught with the gravest consequences. When we turn to his chapter on treatment it is word for word, line for line, that of severe sciatica, so that, after all, the question is one of scientific rather than therapeutical interest.

We commend this vigorous essay to the notice of practitioners who see much of sciatica, for it cannot fail to stimulate their interest in their cases and may be the means of enabling them to make a differential diagnosis which will be all to their credit, even though it may not materially modify the line of treatment.

(a) "Sciatica: A Fresh Study." By Wm. Bruce, M.A., LL.D., M.D.Aberd. With notes of nearly 700 cases. Pp. 187. London: Baillière, Tindall and Cox. 1913. Price 5s. net.

MEDICAL NEWS & PASS LISTS.

The Royal College of Surgeons of England.

A QUARTERLY meeting of the Council of the Royal College of Surgeons was held last week, with Sir Rickman J. Godlee, President, in the chair.

H. D. Harrison, M.B., Toronto University and Middlesex Hospital, was admitted a Fellow of the College; S. Adams, A. Chapman, and H. G. James, of Guy's Hospital Dental School, and P. Blake, of the Middlesex and Royal Dental Hospitals, were admitted Licentiates in Dental Surgery.

It was decided, in conjunction with the Royal College of Physicians, to add St. Chadd's College, Denstone, Bournemouth Municipal College, and Bournemouth School to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics.

Sir Watson Cheyne was appointed Hunterian Orator for the year 1915, and Mr. C. J. Symonds, F.R.C.S., was nominated a representative of the College on the Council of Queen Victoria's Jubilee Institute for Nurses.

A vote of thanks was given to Mrs. King, of Milton,

Massachusetts, for presenting a clock to the College in memory of her father, the late Dr. W. C. B. Fifield, M.R.C.S., of Boston, U.S.A.

Suicide of an Irish Doctor.

A SAD event occurred on Tuesday, the 6th inst., when Dr. James J. M'Greal, J.P., L.R.C.P.I., the popular Medical Officer of the Louisburgh dispensary district, committed suicide at his residence, Tooreen Lodge, Louisburgh, by taking a dose of morphia. Dr. M'Greal, who was a native of Westport, was only 29 years of age Four years ago he was appointed Dispensary Doctor for the Louisburgh district. The death of his young child some weeks ago appears to have unhinged his mind, and since that event took place he was apparently in depressed spirits.

Mr. John Kelly, J.P., Coroner for Mest Mayo, held an inquest on the body. Dr. Gill, Westport, who examined the remains, deposed that in his opinion deceased died from morphia poisoning.

The jury found that death was due to morphia poisoning, self-administered during temporary insanity, and added a rider tendering sympathy to his bereaved widow and relatives.

Death under Anæsthetic.

THE Birmingham Coroner (Mr. Isaac Bradley) held an inquest at the Victoria Courts on the 2nd inst. concerning the death of Thomas Bowler, aged 32, a railway goods foreman at Bromford Lane Station, of 40 Church Street, West Smethwick.

From the evidence it appeared that Bowler left home on Monday morning apparently in his ordinary state of health, and was brought home in the afternoon. He was ill and complained of internal pain. He did not say that he had sustained any injury at his work. He became worse, and was removed to the General Hospital. At this institution, Dr. Sampson, the House Surgeon, stated that his complaint was diagnosed as general peritonitis. Dr. Seymour Barling was summoned, and Dr. Growt administered an anæsthetic for operation. The patient took the anæsthetic very well, but during the operation—during which it was found that Bowler was suffering from a twisted gut—Bowler's respirations became slower, and, though efforts were made to restore him, he died shortly afterwards. The cause of death was shock following the operation.

The jury returned a verdict according to the medical evidence, and said they were satisfied the anæsthetic was properly administered.

Fever Epidemic passing in London.

THE returns for a fortnight in regard to the fever epidemic which has swept over London during the past six months, just issued by the authorities of the Metropolitan Asylums Board, shows that the outbreak is now abating in severity. There is a decrease in the number of patients remaining under treatment of 197, as compared with a fortnight since. The outbreak is, however, still serious, as is evidenced by the fact that in the last two weeks no fewer than 1,057 cases have been admitted.

The Chesterfield Post-Graduate Lectures.

THESE lectures, founded in 1895 with a silver medal by the Earl of Chesterfield to promote the study of dermatology (and which is open for competition to those who have attended three-fourths of the lectures), are free to medical practitioners on presenting their cards and to medical students who desire to attend regularly, and will be resumed at St. John's Hospital for Diseases of the Skin, Leicester Square, London, on Thursday evening, January 15th, at 6 p.m., by the Chesterfield Lecturer, Dr. Morgan Dockrell. After each lecture demonstrations will be given on special cases, followed by clinical instruction up to 7.30 o'clock on patients presenting themselves in the Out-patient Department. The lectures are essentially practical, and deal fully with diagnosis and treatment, being illustrated by large diagrams, clinical and microscopical, specially prepared for each lecture.

University of London.

THE following candidates passed the M.D. emamina-tions during December, 1913 :—

Branch I.—Medicine.—Thomas Beaton, B.S., Wilfrid E. Burrows, B.S., B.Sc., Hazel H. Cuthbert, B.S., Reginald R. Elworthy, B.S., William C. Fowler, B.S., Geoffrey Hadfield, B.S. (University Medal), Robert H. H. Jolly, B.S., Cicely M. Peake, B.S., Ernest E. A. T. Rigg, B.S., Harry D. Rollinson, B.S., Alfred R. Spencer, George E. S. Ward, B.S., Gordon R. Ward, B.S.

Branch III.—Mental Diseases and Psychology.—Ralph Brown, B.S., Alfred A. W. Petrie, B.S.

Branch IV.—Midwifery and Diseases of Women.—David J. Harries, B.S., Reginald Larkin, Arthur A. Straton, B.S. (University Medal).

Branch VI.—Tropical Medicine.—Robert Kelsall, B.S. (University Medal).

The following passed the M.S. Examination :—

Branch I.—Surgery.—Harry C. R. Darling, M.D., Ernest F. Finch.

Army Medical Service.

THE following official appointments and retirements have been gazetted :—Surgeon-Gen. O. E. P. Lloyd, V.C., C.B., is placed on retired pay, January 1st, 1914; Col. W. G. A. Bedford, C.M.G., to be Surgeon-General, vice O. E. P. Lloyd, V.C., C.B., January 1st, 1914; Lieut.-Col. C. Birt, from the Royal Army Medical Corps, to be Colonel, vice W. G. A. Bedford, C.M.G., January 1st, 1914; Col. T. J. R. Lucas, C.B., M.B., on completion of four years' service in his rank, retires on retired pay, January 2nd, 1914; Brevet-Col. R. S. F. Henderson, M.B., K.H.P., from the Royal Army Medical Corps, to be Colonel, vice T. J. R. Lucas, C.B., January 2nd, 1914; Major J. V. Forrest, M.B., Royal Army Medical Corps, to be a Deputy Assistant Director General (attached to the Department of the Director of Military Operations at the War Office), vice Major C. E. Pollock, December 29th, 1913.

Royal Army Medical Corps.

THE following official appointments and retirements have been gazetted :—Lieut.-Col. A. R. Aldridge, C.S.I., M.B., retires on retired pay, January 3rd, 1914; Brevet Lieut.-Col. E. M. Pilcher, D.S.O., to be Lieut.-Colonel, vice C. Birt, January 1st, 1914; Major W. G. Beyts to be Lieut.-Colonel, vice E. M. Pilcher, D.S.O., supernumerary, January 1st, 1914; Major W. D. Erskine, M.B., retires on retired pay, January 3rd, 1914. The following officers are restored to the establishment :—Capt. R. J. C. Thompson, December 12th, 1913, and Lieut. B. Woodhouse, January 1st, 1914.

Apothecaries' Hall of Ireland—Election of Examiners.

Court A.—Chemistry and Physics: Professor Hugh Ryan, D.Sc., J. J. O'Sullivan, L.R.C.P. and S.I., D.P.H., Walter Healy, L.A.H., L.P.S.I. Biology and Physiology: Professor Bertram J. Collingwood, B.A., M.D., James C. McWalter, M.A., M.D., D.P.H., Barrister-at-law. Anatomy: Andrew Charles, F.R.C.S.I., Bernard Burke-Kennedy, L.R.C.S.I. Materia Medica: Thomas G. McGrath, L.R.C.P. and S.I., Walter Healy, Bernard Burke-Kennedy, L.R.C.S.I. Pharmacy: John D. Crinion, L.R.C.P. and S.I., Thomas G. McGrath. Pathology: Andrew Charles, F.R.C.S.I., Robert M. Bronte, L.R.C.P. and S.I., D.P.H. Medical Jurisprudence and Hygiene: Sir Charles Cameron, C.B., M.D., F.R.C.S.I., Robert P. McDonnell, F.R.C.S.I., D.P.H. Medicine: John Marshall Day, M.D., D.P.H., John Lumsden, M.D. Midwifery: Patrick T. McArdle, M.B., B.Ch., John Sheppard, L.R.C.P. and S.I., Trevor N. Smith, F.R.C.S.I. Ophthalmology: Edward Magennis, M.D., M.Ch., D.P.H., Herbert C. Mooney, F.R.C.S.I., D.P.H.

Court B.—Materia Medica: John D. Crinion, Thos. G. McGrath. Pharmacy: O'Connell J. Delahoyde, Walter Healy. Chemistry: Thomas G. McGrath, Walter Healy.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ERRATA.—Owing to a typographical error in our obituary column last week, the name of Professor Gibson was mis-spelled Gilson, and Prof. Crum Brown, Owen Brown.

M.B., Ch. B. (East Riding).—The recent researches of Dr. Alexander Paine and Dr. F. J. Poynton show that malignant endocarditis may be of a rheumatic nature, for a diplococcus, identical with the "diplococcus rheumaticus" has been isolated from endocarditis, both of the simple and also of the malignant type.

"MACULA LUTEA" (London, W.).—It has been shown by Prof. von Hess, of Munich, that fish are totally colour-blind, but they can distinguish the varying degrees of light and shade.

THE PANEL PATIENT.

THE panel chemist looked at the prescription. "You'll have to pay a penny for the bottle," he said. "Nay, I'll not," came the reply; "Government medicine's free. I've brought a washed ginger-beer bottle 'ere, and I'll trouble you to put it in that."—*Manchester Guardian.*

DR. R. P. (Surrey).—It is quite open to discussion whether adenoid hypertrophy may not be a tuberculous manifestation. The frequent association of enlarged lymphatic glands would render the findings of a von Pirquet cutaneous reaction positive in a large number of cases, but it would be difficult to decide without further test the question of the tuberculous nature of adenoid growths.

M.D., U.S.A. (Boston).—The subject is well worthy of ventilation, and it would be quite suitable for the columns of a medical journal.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 14TH.

HUNTERIAN SOCIETY (St. Bartholomew's Hospital, E.C.).—9 p.m.: Lecture—Mr. J. Cantlie: Recent Advances in Tropical Medicine (with lantern slide demonstration).

THURSDAY, JANUARY 15TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. J. J. Pringle, Dr. H. MacCormac, Dr. J. H. Sequeira, Dr. Knowsley Sibley, Dr. G. Pernet, Dr. A. M. H. Gray, Dr. A. Whitfield, and others.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Doekrell: Baldness—I., Bacillary; II., Parasitic; III., Atrophic; IV., Inflammatory; V., Systemic Intoxication.

FRIDAY, JANUARY 16TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOLOGY) (1 Wimpole Street, W.).—5 p.m.: Communications and cases by Dr. William Milligan, Dr. J. C. Potter, Mr. G. J. Jenkins, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (St. Thomas's Hospital, S.E.).—8.30 p.m.: Inspection of Electrical Department and Demonstrations.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital).—8 p.m. Special Clinical Evening.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (Rooms).—8.30 p.m.: Prof. R. Newstead—The Bionomics and Structural Characters of Glossina illustrated by lantern slides and an extensive collection of museum specimens illustrative of all the known species of the genus).

ROYAL INSTITUTE OF PUBLIC HEALTH (Lecture Room of the Institute, 37 Russell Square, W.C.).—Course for Tuberculosis Officers, School Medical Officers, Medical Practitioners, etc.—5 p.m.: The Diagnosis and Treatment of Tuberculosis, etc. Lecture I., Dr. C. Addison, M.P.: The Problem in Relation to Insurance and Public Health.

TUESDAY, JANUARY 20TH.

CHELSEA CLINICAL SOCIETY (St. George's Hospital).—8.30 p.m.: Paper by Mr. Ivor Back, "The Mayo Clinic and some other things in America."

ROYAL SOCIETY OF MEDICINE (SECTION OF THERAPEUTICS AND PHARMACOLOGY).—4.30 p.m.: Discussion on "The Therapeutical Value of Hormones," opened by Professor G. R. Murray. The following will take part:—Professor E. H. Starling, Dr. Leonard Williams, Dr. T. R. Elliott, Dr. H. H. Dale, and the President (Dr. Hale White). 5 p.m.: General Meeting of Fellows—Ballot for Candidates for the Fellowship.

Appointments.

BROADBENT, SIR JOHN, Bart., M.D.Oxon., Full Physician on the Staff of St. Mary's Hospital, Paddington.

GRANT, JOHN C. B., M.B., Ch.B.Edin., House Surgeon to the Ear, Nose and Throat Department at the Bristol Royal Infirmary.

JONES, R. LLEWELLYN, L.R.C.P., M.R.C.S., House Surgeon at the Bristol General Hospital.

LANGMEAD, F., M.D.Lond., Physician-in-Charge of Out-patients at St. Mary's Hospital, Paddington.

ORR-EWING, HUGH JAMES, M.B., B.S.Lond., L.R.C.P., M.R.C.S., House Physician at the Bristol Royal Infirmary.

PARROT, H. W., M.B., B.S.Lond., House Physician at the Bristol General Hospital.

WADE, E. W., M.B., B.S.Lond., House Surgeon at the Bristol Royal Infirmary.

WALKER, H. B., M.B., B.S.Lond, House Surgeon at the Bristol Royal Infirmary.

Vacancies.

Liverpool Education Committee—School Medical Officers (two) to assist the Medical Officer in charge. Salary £250 per annum for first year, £300 for the second, and £350 for the third year. For full particulars see advertisement.

Royal City of Dublin Hospital.—Resident Medical Officer.—Applications to Hon. Sec. of Medical Board, Upper Baggot Street. (See advert.)

Joint Counties Asylum, Carmarthen, South Wales.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Scarborough Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and allowance for laundry. Applications to the Hon. Secretary.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £200 per annum, with board, lodging and washing. Applications to the Medical Superintendent.

County Asylum, Whittingham, Preston.—Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £180 per annum, with apartments (not board), attendance, light and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk and washing. Applications to the Medical Superintendent, Asylum, Maidstone. The appointment will be made subject to the provisions of the Asylums Officers' Superannuation Act, 1909.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, fuel, lighting, washing and attendance. Applications to the Medical Superintendent.

Warwick County Asylum, Hatton, near Warwick.—Second Assistant Medical Officer. Salary £200 per annum, with board, lodging and laundry. Applications to Dr. Miller, Medical Superintendent.

York Dispensary.—Resident Medical Officer. Salary £140 per annum, with board lodging and attendance. Applications to Joseph Peters, Secretary, 4 New Street, York.

Births.

BIRD.—On Jan. 6th, at Old Croft, Godalming, Surrey, the wife of Gerald F. Bird, M.B., of a son.

BIRKS.—On Jan. 5th, at 2 Harpur Place, Bedford, the wife of Guy Thornton Birks, M.B.Cantab., of a daughter.

GRAY.—On Jan. 9th, at De Walden Court, the wife of H. Tyrrell Gray, F.R.C.S., 60 Harley Street, of a daughter.

POOLER.—On Jan. 4th, at Strathray, Leigh Road, Westcliff-on-Sea, the wife of Dr. J. Read Pooler, of a daughter.

STREATFEILD.—On Jan. 10th, at 42 Ovington Square, S.W., the wife of Raymond Streatfeild, M.R.C.S., L.R.C.P., of a daughter.

YOUNG.—On Jan. 8th, at 28 Hornsey Rise Gardens, N., Helen, the wife of Graham Pallister Young, M.B., B.S., late of Stoney Stanton, Leicestershire, of a son.

Marriages.

ROBINSON—GREEN.—On Jan. 9th, at St. Matthew's, Ealing, Hamilton Robinson, Mus.D., to Ruth Withers Green, youngest daughter of Alfred Withers Green, M.R.C.S., L.R.C.P., of Wardrobe Place, E.C.

M.R.C.S., L.R.C.P., of Wardrobe Place, E.C.

STOCKS—AIKMAN.—On Jan. 10th, at the Church of St. Marylebone, London, Reginald Woolsey Stocks, Medical Officer of Health, West Bromwich, son of the late Dr. Frederick Stocks, of Clapham, S.W., and Mrs. Stocks, of Tankerton, Kent, to Anna Daisy, eldest daughter of Mr. and Mrs. J. H. Aikman, of Jamaica and St. Vincent, B.W.I.

Deaths.

BOLDERO.—On Jan. 7th, at Langford, Solihull, Frederick Boldero, M.R.C.S.E., late of Penkridge, Staffs, aged 72.

COMPTON.—On Jan. 5th, at Keyingham, Hull, Maurice Winzar Compton, M.R.C.S., L.R.C.P., son of the late Rev. T. H. Compton, aged 36.

HARSANT.—On Jan. 9th, at The Hive, Exeter Road, Bournemouth, Joseph George Harsant, M.D., M.R.C.P., aged 52.

HEWLETT.—On Jan. 7th, at 12 Colinette Road, Putney, S.W., after a long illness, Louise, the dearly-loved wife of R. Tanner Hewlett, M.D., F.R.C.P.

HOLMES.—On Jan. 7th, at Boston Spa, Frederick Holmes, M.R.C.S., L.S.A., late of Leeds.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, JANUARY 21, 1914. No. 3.

NOTES AND COMMENTS.

Hospitals and the Insurance Act.

THE future of the small hospitals in relation to the National Insurance Act is surrounded with grave doubts, difficulties and anxieties. Already not a few of them have been reduced to ruin by the operations of Mr. Lloyd George's measure. So far the central authority at Whitehall has declined to accept any responsibility whatever for the injury done to these institutions, regardless of the fact that an immense number of insured persons are daily and hourly receiving skilled medical aid from the voluntary charities. In answer to an inquiry addressed to the Home Office, it was intimated in a half-hearted fashion that the local committees had power to make grants to hospitals, and applications might be addressed to them accordingly. It seems highly probable that before any help came from that quarter many small hospitals would have already closed their doors and ended their career beneath the cloud of bankruptcy. Possibly Mr. Lloyd George has foreseen some such process of elimination, and has accustomed himself to the idea of a general massacre of philanthropic institutions as a preface to some cherished scheme of a State-aided service. From the point of view of the public health, as we have often pointed out in these columns, such an attitude would be disastrous to the last degree. The extinction of the special hospitals would inflict on the one hand a deadly injury upon the progress of medical science, and, on the other, upon the tens of thousands of members of the insured classes who now receive from those institutions the best and kindliest medical services that can be commanded in the whole world.

The Last Straw.

As a matter of fact, many panel doctors send their patients to hospitals, great and small, and as they are paid a fixed sum *per caput* for medical benefits, it is only in accordance with human nature that they should act in that way. That means, however, that the hospitals are doing work that is already paid for by the taxpayers. Insured, employers and general taxpayers find between them the money necessary to supply medical benefits to all members of the community whose incomes fall below certain moderate limits. If, then, a part of that medical service is handed on to the voluntary hospitals, it is clear that someone else is helping Mr. Lloyd George in his Herculean task of supplying a sound medical service to the working classes. As a matter of fact, nothing can supersede the skilled aid obtainable at the special hospitals. It would be futile to expect under any system of medical education or of medical practice that a panel doctor could be proficient in such highly specialised branches of professional work as those which deal with the eye, throat, skin, diseases of the nervous system, women, and so on. When the time comes for the revision of the Act it is to be hoped that the Chancellor of the Exchequer will have thought out some scheme of relief for the voluntary medical charities of the Kingdom, that is to say, of such of them as may have survived the stress thrown upon them by the Insurance Act. It was bad enough for the small hospitals to be ignored by the great distributing funds, but a last straw has been added by extracting pence from insured persons to the direct and indirect impoverishment of the small hospitals!

Pneumonia in Virgin Soil.

THE recent report of Sir Almroth Wright on pneumonia in the Rand mines, to which we referred last week, furnishes much suggestive information. The conclusion that forms the jumping-off point, so to speak, of his work, is the fact that natives attacked with pneumonia are unable to form antibodies in their system, in opposition to what occurs in the case of white men. The explanation appears to be that pneumonia is a thing unknown in the native kraals, so that the bodies of the Kaffirs have not been educated by generations of exposure to the pneumonic organisms. When the latter invade the lungs of a native, therefore, they are able to run riot, unrestrained by the antibodies that form with lightning rapidity in more civilised frames. The fact is that when the natives are exposed to the bacterial virus of pneumonia in the bad sanitary environment of the Rand mines they die off like sheep because the disease has lighted on virgin soil. Medical science, however, has now appeared on the scene, and supplies an antidote in the shape of preventive and curative inoculation, measures that are recommended in Sir Almroth Wright's report. The central point of this interesting investigation is that the key to the pneumonia lies mainly in the defective resistance of the native against a disease of his environment.

Institution Treatment of Scabies.

A FEW weeks ago the principal Medical Officer of the Metropolitan Asylums Board was approached with the suggestion that it was the Board's duty to provide in-patient accommodation for cases of scabies. Every dermatologist will agree that it is the exception, rather than the rule, for scabies to be so severe as to require anything more than a few baths and the thorough application of a parasiticide ointment, in addition, of course, to the adequate disinfection of the clothes. Should such cases arise they could be dealt with, under proper precautions, in the

ordinary wards of an infirmary or an hospital, although, so far as our experience goes, it must be confessed that hardly any institution of the kind would knowingly admit such a case. In view of the comparative ease with which uncomplicated scabies is cured, the Medical Officer of the Board could not advise that special accommodation should be provided for children suffering from the disease. If ordinary care be taken there is little risk of scabies spreading to other patients while the very simple, yet effective, means of treatment in institutions is carried out. Beds in voluntary hospitals are too precious to be occupied by trivial cases; but their provision is surely justified in public institutions where the eradication of a most undesirable infection is concerned.

LEADING ARTICLES.

THE ETHICS OF HOSPITAL MEDICAL STAFF APPOINTMENTS.

THE election of the honorary medical staffs of voluntary hospitals is clearly a matter of public and of professional interest. That such appointments should be conducted wisely and fairly, and in such a way as to secure the best men available, is a plain duty imposed upon the management—in the first place by honourable tradition; and, in the second, almost invariably by written rules. For the most part little can be said against the methods of election in the majority of London hospitals, although now and then one sees evidence of the undue favouritism and bias which is termed "nepotism." For all that, the defect is not as a rule offensively glaring, and it is natural enough that the son or the nephew of a man who has added to the lustre of a great hospital should gain any electoral privilege that may be attached to his relationship—provided, of course, that he is eligible on other grounds. As a matter of fact, the method of election to staff appointments is, so far as we know, without exception carefully set forth in the charter or the rules and regulations of each individual charity of any importance, and the competition is conducted under rigidly defined conditions. These posts are among the prizes of medical life, and their disposition is jealously watched both by hospital boards and by the medical profession. Of late, however, several vacancies have been filled up in a way that, in our opinion, calls for full inquiry and explanation in the interests of the hospitals concerned, not less than of the public and of the profession from whose ranks the honorary posts are filled. Curiously, the two elections to which our attention has been called are those of dermatology—the one at the West London and the other at the London Temperance Hospital. In both cases the vacancy was announced in the usual way. Applicants sent in their testimonials and appeared before the Board, but no formal appointment was made at the time. Later, the post has been filled up apparently in a secret and irregular manner. At the West London election competition was keen, and four excellent and irreproachable candidates were selected to appear before the Board of management. After waiting an hour or more at the appointed meeting place, they were told that no appointment would be made that night. No further official intimation of any kind reached the four candidates, and the work of the skin department was carried on *pro tem.* by the two clinical assistants. Six months later a dermatologist, who had not been among the selected candidates, was gazetted in the medical journals as appointed to the post. As the vacancy had not been advertised a second time, it is obvious that this procedure was distinctly high-handed and irregular. We venture to say that it is incumbent upon the management of the West London Hospital to justify their action by specific reference to the rules and regulations of their hospital with regard to elections. If no such regulations exist, then it is high time that a code were introduced, otherwise future appointments will degenerate from honourable contests to the level of Tammany, with its backstairs intrigue and wire-pulling agencies. It seems hardly fair that an institution that enjoys the patronage of His Majesty the King should permit its elections to be conducted on lines the fairness of which are in the least open to question. Turning to the London Temperance Hospital, the circumstances differ considerably. Candidates met together in due course at an appointed date and were interviewed by the Board. They, too, were informed that no appointment would be made on that day, on the plea that several members of the staff were away on their holidays. Here, again, candidates were not informed as to the ultimate result; but many weeks later it transpired that the post had been given to one of the candidates—curiously enough the only one amongst them who was not a practising dermatologist. In this case it seems to show a certain amount of laxity that so much unnecessary delay occurred between the advertised date of election and the completion of the appointment. It may be, of course, that the action of the Electing Committees in both hospitals was justified by special facts and conditions known to themselves, and their procedure may have been in accordance with the rules of their respective institutions. In any case, the governors of the hospital are entitled by right, and the medical profession by courtesy, to demand a detailed explanation of the affair. Failing the grounds of such complete justification, it seems not unlikely, from a purely legal standpoint, that either of the selected candidates or any governor of the hospital might succeed in obtaining an injunction in Chancery to set aside the election. Public charitable bodies, it must be remembered, are subject to legal restrictions which are usually more or less clearly defined. In the case of a recent election of a lay officer of St. George's Hospital, the governors seem to have promptly resented the attempt to confer upon the late Honorary Treasurer of that institution the paid post of Secretary Superintendent. An action

of that kind is hardly calculated to increase the confidence of the public in the wisdom of the management. In so far as the overwhelming majority of voluntary medical charities of the United Kingdom are concerned, it is undoubtedly true that their mistakes are due to defective judgment, and are in no sense whatever the outcome of unworthy personal motives. At the same time, it would be simply calamitous were hospital boards generally to assume a right to set aside rules and regulations in order to suit their own views, especially in dealing with such important matters as staff elections.

CURRENT TOPICS.

The Health of the Army in 1912.

THE annual report upon the health of the Army in 1912, issued the other day, contains many points of interest. It is satisfactory to note that the death-rate and the number of those constantly sick are both lower than in the preceding year, and a still further decrease is recorded in the ratios of admissions for enteric fever, malaria, dysentery, alcoholism, and also for all forms of venereal disease. Already the use of salvarsan in the treatment of syphilis has caused a decrease of five days in the average duration of each case of this disease compared with 1911, and, as the use of this remedy becomes more general, a further reduction may be expected. The total inefficiency caused by sickness, as shown by the number constantly under treatment in both hospitals and barracks, was 31.59 per 1,000 of mean strength, as compared with 31.83 in the previous year. Emigration and improved trade are stated to be the chief causes of the decrease in the number of recruits medically examined. Experience shows that the best results from recruiting stations are obtained when medical examiners regard the medical inspector as a colleague and friendly adviser. Severe criticism may be necessary sometimes, but it may easily be pushed too far, and produce the undesirable result of an abnormally high rejection ratio. The increasing value of the modern system of physical training, founded on the Swedish system, at the various depôts, is now more generally realised. Considerable progress has been made in the sanitary administration of barracks and camps, and also in the general knowledge of sanitation among all ranks. The value of the experimental and research work carried on at the Royal Army Medical College and School of Army Sanitation at Aldershot can hardly be overestimated. An improved method of water purification for troops in the field, the substitution of an "iron ration" consisting of preserved meat, biscuit, cheese, meat extract, tea and sugar, for the old emergency ration, are among some of the medico-military problems that have been partially, if not wholly, solved; while the important subject of the preservation of Army biscuits packed in tins from the attack of moths is also being investigated. Diseases of the nervous system show the highest ratio (1.61) of invaliding, while that for syphilis (.11) is the lowest on record. Although there is room for improvement in many respects, yet the report is one which may be regarded with considerable satisfaction.

Lister and King's College.

BY the unveiling of a tablet at King's College last week in commemoration of Lord Lister's connection with that institution, a fitting local tribute has been paid to the memory of one who, by his advances in surgery, "saved more lives than Napoleon destroyed." The ceremony was performed by Lord Rayleigh, who served for a while under Lister at the Royal Society, and an address was also delivered by Dr. W. P. Herringham, Vice-Chancellor of the University of London. It may be recalled that Lister wrote to the Governors of King's College, who had invited him to succeed Sir William Fergusson as Professor of Surgery, saying that he would only accept the offer if he could be given full opportunities for teaching clinical surgery, and if he could appoint, in separate wards to be allotted to him, his own Edinburgh-trained house-surgeons, dressers, and nurses. Few men would have been so bold as to dictate the terms of an appointment in this fashion. But then, Lister was unique. He got his way, and was appointed Professor of Clinical Surgery in 1877, delivering his introductory lecture at King's College on October 1st of that year. From that time onward, in spite of numerous bitter attacks, some of them of a personal nature, his position was secure, and now the world has cause to honour the memory of one who revolutionised the art of surgery. He that runs can now read the words on the tablet, erected in the corridor outside the chapel, as follows:—"In affectionate and respectful memory of Joseph Baron Lister, F.R.S., O.M., Professor of Clinical Surgery in King's College from 1877-1892, and for many years Consulting Surgeon to the King's College Hospital, Member of the Council and Life Governor of the College, this tablet is erected. His name will be handed down to posterity as the founder of antiseptic surgery, one of the greatest discoveries in history and a source of inestimable benefit to mankind."

Radium and Cancer.

IT is now several years since it was first shown that radium is of use in the treatment of cancer. Radio-active substances apparently exercise some special influence on malignant cells, which does not so much inhibit their growth and multiplication as cause their atrophy. For several years evidence leading to this conclusion has been accumulating, and some important facts bearing thereon were made public last week by Dr. Lazarus-Barlow. According to the statement attributed to him by the *Times*, some thirty-two patients suffering from inoperable cancer were, as the result of treatment by radium, rendered capable of discharge from the Middlesex Hospital in the three months from June to September of last year. This is stated to be an unprecedented event in the history of the hospital. These results are important, though it is, of course, as yet impossible to speak of them as cures. We regret to have to add that we cannot congratulate Dr. Lazarus-Barlow either on the manner or on the channel of his communication. At the same time, it must be confessed that in recent documents prominent medical men have not hesitated to append their names and even their hospital and other posts to newspaper declarations of a medical nature. The memory of a certain joint manifesto congratulating a London newspaper on its policy, and the petition for a Royal Commission on venereal diseases is not likely to fade in a day. Moreover, while admitting the inconclusiveness of his experience, Dr. Lazarus-Barlow permits himself to use language calculated to lead to the formation of false hopes: "If 150 milligrams of radium were buried in a cancerous tumour, it simply withered up and disappeared," is a sentence that we fear will not stand either grammatic or scientific criticism.

Fish as Food.

THERE can be little doubt that much benefit would accrue to town dwellers if they could be induced to exchange a portion, at least, of their meat for fish as a daily food. The evils of excessive meat-eating by those who have little or no opportunities for regular physical exercise are well known, for a glance at the comparative analyses of the flesh of fish and meat shows that the former entails considerably less labour on the part of the digestive organs than the latter. Popularly, fish is supposed to be "good for the brain," and this belief has some scientific foundation in that it contains fewer extractives than meat. One thing is certain—namely, that the economic value of a small fish is quite out of proportion to its size, so that the poor may dine off sardines to greater physiological advantage than the rich off soles and turbot. As Sir James Crichton-Browne remarked the other day, at the dinner of the Fishmongers' Company, a large proportion of our countrymen do not half realise as it should the real value of fish foods. Smoked, salted, and pickled fish are best avoided by dyspeptics, but even those of weak digestion can partake of the "chicken of the sea," the whiting, or the sole. The oyster, of course, holds the record for the shortness of time required for digestion. According to Martial, extravagant prices were frequently paid for fish by Roman epicures, the price of a slave being less than that sometimes given for a fish. Fortunately, expense need not stand in the way of the poorest consumer from drawing upon the great larder of the deep, and, were fish to be more generally eaten by the public, the latter would certainly gain in health thereby.

Doses.

WE are up against the dose question again. There is some risk of a new "Pharmacopœia" appearing in the near future, and the medical world has been duly exercising itself about an easy way to remember officinal doses. The current idea is to divide tinctures into three classes: "Per-tinctures," "tinctures," and "sub-tinctures." The doses are to be 5 to 15 minims, ½ to 1 drachm, and 2 to 4 drachms respectively, and all stragglers are to be brought into one of these three lines. The advantage of this scheme is that a prescriber would know that each group name carries a specific dose; whereas now a medical man often has to rely on his mistakes being pointed out by the faithful pharmacist. It is probable that the Insurance Act is responsible for this discussion. Doctors who have dispensed modified or unmodified stock mixtures for years find themselves unfamiliar with the responsibility of committing their treatment to black and white. Chemists who formerly dispensed one or two prescriptions a week now deal with hundreds in a like time. The result is a probably groundless feeling of insecurity. A doctor may make a mistake and a chemist pass a dangerous dose. The group idea is clever, but we are not sure that official doses are particularly desirable. They tend to harmful limitation. A radiographer would laugh at the idea of 20 grains of bismuth carbonate as a full dose. Of course, it is useful to have some sort of guide for the administration of an unfamiliar drug which is what the Pharmacopœial limits are expressly stated to be. But we are apt to treat the official bounds as definite terminals to our posological excursions. We must remember not to let ourselves be mastered by our methods, but to keep them in proper subjection. After all, it does not require an undue amount of intellectual effort to do the two things that are needful: First, to remember a few of the B.P. doses, and, second, to forget most of them.

Cancer and the Public.

THAT a large amount of unnecessary suffering would be prevented, and an actual saving of life would be procured, by the better education of the public will be generally admitted. It is difficult, however, to bring home the crude facts relative to the prevention and treatment of such a disease as cancer without frightening or offending those whom it is desired to benefit. To the Portsmouth Health Committee and its energetic Medical Officer, Dr. A. Mearns Fraser, must be given the credit for being the first municipal authority to tackle the subject boldly in the interests of the public health. They have wisely decided (says our contemporary *The Medical Officer*) to spread a knowledge of what may be termed the warning signals of the onset of cancer, so that those concerned shall be apprised of the necessity for seeking medical advice early and of the danger of delay. To this end an address was given last week in the Town Hall by Mr. C. P. Childe, F.R.C.S., Senior Surgeon to the Royal Portsmouth Hospital, devoted principally to the giving of instruction on the early symptoms of cancer. A public notice will appear in the local Press, at regular intervals, regarding the advisability of the early removal of cancer, and, therefore, of its timely recognition. The notice is couched in simple language, and we do not think that any exception can be taken to the statements it contains. If any additional warnings were needed, we might suggest the inclusion of a paragraph emphasising the danger and folly of resorting to so-called "cancer-cures," instead of going at once to a medical man for advice. Meanwhile the municipality of Portsmouth may be congratulated upon taking the lead in what may well develop into a great national campaign against cancer.

Statistics of Venereal Disease.

SOME of the most valuable evidence yet given before the Royal Commission on Venereal Diseases was that given by Mr. Ernest Lane, whose experience at St. Mary's and the Lock Hospital renders his opinions of special value. He said that "in his opinion, and in that of many persons well qualified to judge, venereal diseases are attended by just as great a mortality as tuberculosis or cancer, although it is not possible to obtain figures to support this view." This is probably putting matters too high, but all men will agree that it is desirable that accurate figures should be obtained, particularly at the present time when so many alarmist articles and pamphlets are appearing not only in the medical papers, but in the lay Press also. We hold with Mr. Lane that any form of notification would tend to keep those suffering from these diseases from seeking medical help. It is easily understood that if a patient, man or woman, knew that his or her condition would become known to anyone besides the doctor, and that information concerning him would be entered on an official list as a result of consulting a medical man for treatment, then medical advice would only be sought as a last resource. Fairly accurate statistics might, however, be obtained by another method without these disadvantages. A printed form might be furnished annually to all medical practitioners, on which they would return the numbers of men, women and children treated by them for all forms of venereal and allied diseases. A small fee must, of course, be paid for the return. We believe that, by some such plan as this, fairly

accurate statistics could be gained, and we are sure that the medical profession would give cordial assistance. As no names would be divulged, we do not think that there would be any effect in the way of deterring patients from seeking treatment.

Aeroplanes in Warfare.

THE progress of aviation has been so great within the last quarter of a century that many of the prophecies of the distinguished author of "The War of the Worlds" seem likely to come true. At any rate, now that the Royal Flying Corps has become a recognised unit of our military service, it is time that the medical aspect of the question received adequate attention. An interesting lecture was given at the Royal United Service Institution last week by Lieut-Col. J. D. F. Donegan, R.A.M.C., on "The Uses of Aeroplanes to the Army Medical Service in the Field." It was pointed out that although balloons and kites in the ordinary sense could be of no service, a small balloon, lit with a dry-cell battery, might be a better means of indicating hospitals at night time than the present two white lights. Similarly, failing space for a Red Cross flag pegged out on the ground, a Red Cross kite by day might be used to protect hospitals from airships engaged in dropping explosives. Airships might come to be used for the transport of wounded, but meanwhile aeroplanes were already capable of performing useful medical services. Among other possible uses were:—(1) Scouting for wounded on the battlefield; (2) the simplification of the duties of administrative officers by enabling them to provide medical assistance in a very short time at any given spot; (3) the transport of specialists, so that the wounded soldier in the field would have the same chance for his life as he would in time of peace; (4) the reinforcement of the medical staff at any given spot; (5) enabling the administrative officer to see for himself the conditions prevailing in the disposal of the wounded; (6) the reduction of correspondence in the field; and (7) the provision of surgical assistance. The idea of carrying on an aeroplane an operating table with surgical appliances for 15 or 20 operations, an operator, an assistant, and an anæsthetist, together with the pilot, cannot be regarded as an impossibility, for an ingenious table provided with heating apparatus was shown by the lecturer. There is no such word as "cannot" in medical science, so we may look forward with confidence to the future developments of the aeroplane as a medical force in warfare.

PERSONAL.

DR. HILDRED B. CARLILL, M.D.Cantab., M.R.C.P. Lond., has been appointed Physician to the Miller Hospital, Greenwich.

DR. ALFRED G. CALDWELL, M.D.R.U.I., D.P.H., has been appointed Tuberculosis Officer for the County Borough of Reading.

DR. HAYWARD WILLETT, of Liverpool, has been elected President of the North of England Gynæcological and Obstetrical Society.

DR. HERBERT MILVERTON CRAKE, M.D.Liv., D.P.H. Leeds, a native of Spennymoor, has been appointed Medical Officer of Health for the city of Calcutta.

MR. F. A. ANDERSON, M.D., B.Ch., D.P.H.Dub., has been appointed Assistant Surgeon to the Eye, Ear, and Throat Hospital for Shropshire and Wales, Shrewsbury.

DR. EMILY E. FLEMMING, M.D., B.S.Lond., has been appointed to the Joint Lectureship in Medicine at the Royal Free Hospital (London School of Medicine for Women).

MR. MALCOLM HEPBURN, F.R.C.S.Eng., M.D.Lond., has been appointed to the Joint Lectureship in Ophthalmology at the Royal Free Hospital (London School of Medicine for Women).

COLONEL SIR W. B. LEISHMAN, Professor of Pathology at the Royal Army Medical College, has been appointed a member of the Army Medical Advisory Board as expert in Tropical diseases.

DR. J. A. RIVIERE, an authority on the treatment of appendicitis, has been promoted Officer of the Legion of Honour. Dr. Rivière, though living in Paris, was born in Mauritius and is a British subject.

THE vacancies for two Assistant Physicians to the Hospital for Epilepsy and Paralysis in Maida Vale have been filled by the appointment of Dr. Frederick Lucien Golla and Dr. Edwin Greaves Fearnsides.

SURGEON MURRAY LEVICK will deliver a lecture before the Royal Society of Medicine on Monday, January 26th, at 5 p.m., on "The Experiences of Captain Scott's Northern Party from a Medical Point of View."

PROFESSOR G. SIMS WOODHEAD, M.D., F.R.S., will deliver his presidential address to-night (January 21st) before the Royal Microscopical Society, at 20 Hanover Square, W., at 8 p.m., on "The Microscope in Medicine."

DR. CHARLES RONAYNE, of Youghal, has just received His Majesty's permission to wear the Franco-Prussian War Medal, which has just been conferred on him for services rendered as surgeon to French troops during that campaign.

SIR THOMAS BARLOW, Bart., K.C.V.O., F.R.S., will preside at the annual meeting of the After Care Association for poor persons discharged from asylums for the insane, to be held at the Royal College of Physicians on February 23rd.

PRESIDENT WILSON has nominated Colonel Gorgas to be Surgeon-General in the American Army. Colonel Gorgas did brilliant work in connection with the sanitation of the Panama Canal zone, and was recently in South Africa advising upon health conditions in the mines.

IN connection with the growth of the work of the department of the Local Government Board for dealing with tuberculosis, the following have been appointed as three additional medical inspectors:—Drs. Frank Seymour, J. P. Candler, and A. S. McNalty.

MR. G. A. BERRY, F.R.C.S.Edin., LL.D., of Edinburgh, will preside at the forthcoming annual dinner of the past and present students of the Royal Ophthalmic Hospital, to be held on Tuesday, February 3rd, at the Imperial Restaurant, Regent Street, W.

DR. AND MRS. EDGAR BARNES, of Eye, were the recipients the other day of handsome testimonials upon the occasion of their leaving the district after 44 years' residence therein, and as a token of the affection and esteem in which they have been held by all classes.

WE greatly regret to learn on going to press of the sudden and tragic death of Dr. A. S. L. Newington, Physician and joint proprietor of Ticehurst Lunatic Asylum, Sussex. It appears that in order to avoid a collision between his car and a motor dray, Dr. Newington jammed on his brakes too suddenly and was thrown violently into the road, death resulting in a few minutes.

CLINICAL LECTURE

ON

THE CAUSES AND SYMPTOMS OF MUCOUS COLITIS AND ITS TREATMENT BY IRRIGATION, AS DONE AT HARROGATE AND PLOMBIERES. (a)

By ALFRED MANTLE, M.D.Durh., M.R.C.P.Lond.,

Consulting Physician to the Royal Halifax Infirmary.

THE condition of mucous colitis has come before the English profession very prominently during the last ten years, and probably we have to thank the French physician more than any other for giving it a proper recognition, and for the adoption of a sound method of treatment which I may say was first carried out at Plombières and afterwards at Chatel-Guyon. So rapidly is this disorder being recognised by the profession in England since its treatment was undertaken at Harrogate that probably more cases of colitis, coming from all parts of the world, are now treated at Harrogate than at any other European Spa, and the accommodation to meet this demand has had to be increased twice since it was first instituted ten years ago.

I have not infrequently heard it said by medical men and patients that everyone passes mucus, which is quite true, but mucus, when normally secreted, should be invisibly mixed with the fæces, and when it is seen in any quantity, except after some strong purgative, it is abnormal, and usually constitutes the condition of mucous colitis.

I embrace in the term "mucous colitis" that morbid condition of the mucous membrane of the colon in which the predominating feature is the passing of mucus in the stools, most frequently the result of catarrhal inflammation. Inasmuch as the mucus is seen sometimes in viscid masses or ropy strings, and at other times quite membranous and occasionally as casts of the bowel, some have given the name of "membranous colitis" to the latter condition, but the membranous is merely an extension of the mucous form of colitis.

The condition, then, consists of a catarrhal inflammation of the mucous membrane of the colon, and is analogous to the same morbid process seen in the naso-pharynx with which we are all familiar when we have a bad cold, and mucus is constantly poured out from an otherwise more or less moist mucous membrane. It is not at all an uncommon experience to find the subjects of mucous colitis suffering with catarrh of the naso-pharynx as well as of the gastric mucous membrane, and there seems to be in some cases a general infection of the mucous membranes.

In by far the largest number of cases of colitis *constipation* is a prominent feature, and I believe that it is the irritation of the mucous membrane by hardened fæces which so frequently acts as the exciting cause of the colon catarrh. But although constipation is so commonly associated with colitis, in other cases we find an irritable condition of the mucous membrane and increased peristalsis producing more or less diarrhœa. In such cases there is more often infection as a cause, and these patients are frequently from tropical countries where they have become infected, the source of the infection being not always easy to discover. It is, however, the absorption of toxins the result of the catarrhal condition of the mucous membrane which produces the symptoms, and leads the patient to consult the doctor. You know that physiologically the colon is that part of the intestinal tract in which its contents move very slowly, for most of the time in the passage of food from the pylorus to the rectum is spent in the colon. There is, then, more or less danger in the accumulation of undigested food and fæcal matter brought about by an atonic condition of the first part of the colon, and as Sir Arbuthnot Lane puts it, "the colon may become the cesspool of the body."

That there are very many constipated people who get no colitis nor any toxic symptoms from the colon there can be no doubt, for we must remember that with such a strong barrier of defence as we possess in the cells of the mucosa, together with the powerful antitoxic function of the liver, probably it is only when the mucous membrane is inflamed, and its epithelium stripped by abrasions, or is ulcerated—or, again, when the liver or the kidneys become inadequate—that toxins find their way into the circulation.

Mucous colitis is no new disease, but appears to be more recognised than formerly. It seems to run in families and is frequently associated with some gastric disorder, and, as in the case of gastric disturbances which I have shown before, it is usually those of a nervous temperament who are affected, and in both conditions external temperature is a contributory factor in their development. I have reason to think that soil has also some influence, for there is an association between the two conditions, asthma and colitis, and I have two cases at the present time who suffer with asthma and are better on a gravel soil. It attacks the young as well as the old, and at a meeting of the Medical Society of London some time ago Dr. F. J. Poynton quoted three cases of young children, aged respectively 18 months, 2 years, and 2½ years, who had been operated upon for appendicitis following colitis. The symptoms of colitis may simulate very closely those of appendicitis, and cases are operated upon in which the appendix is found afterwards to be normal, and, in my opinion, it is safer removed in such cases, although it may not have shown any acute morbid changes.

It is, however, the family doctor, more than the consultant, who can throw light upon the history and prevalence of the disease, and a practitioner who consulted me concerning the treatment of his own colitis made the following interesting statement of his experience. He practised in a small seaside town, which, for obvious reasons, shall be nameless, and he told me that a large proportion of his patients passed mucus with the stools. In writing to me subsequently, he said "I believe there is something in the locality or atmosphere which makes it so common here, but yet, on the other hand, I believe it is common elsewhere but overlooked. I had it myself, and that is why I am probably up against it more than I should otherwise have been, for until I noticed my own case the trouble here had not been noticed by me. I find that men, women and children—even babies—suffer from this trouble. I believe that it is often overlooked, and that if the other doctors here and elsewhere looked for it they would find it ex-

(a) A lecture delivered at the Medical Graduates' College and Polyclinic, December 3rd., 1913.

tremely common. This statement I make from the large number of cases I get of people from London and elsewhere who send for something else, and upon inquiry as to the bowel condition, I find an enormous percentage have suffered, and are suffering, from mucous colitis. My own small son has just returned from the Midlands with a very bad attack; he has repeatedly had them here, and many children I attend suffer in the same way. I am certain that it runs in families, and not only in families but in members of the same household and community, pointing rather to some infection. My wife, myself, and my young son have all suffered from it. I find it much more common after winds and cold damp weather, the winds preceding attacks being East, N.E. and S.W., which latter are very cold here."

SYMPTOMS.

We come now to the consideration of the most common symptoms of mucous colitis, and it will readily be understood that these will depend largely upon the structures affected by the toxins absorbed. I believe the toxins from the intestine have a special affinity for the nerve centres, and although I am quite prepared to admit that neurasthenia is the cause of constipation, the intestinal wall and reflexes taking on the lethargy common to the neurasthenic condition, yet the bowel stasis increasing bacterial activity, and possibly absorption of toxins, may increase the nervous symptoms of neurasthenia, and also affect the vaso-motor centres, bringing about the circulatory changes which are so common in these cases, for there is usually too little blood in the periphery, hence the cold extremities, and too much in the splanchnic area, with a tendency to congested viscera. There is a feeling of a great sense of fatigue, and patients say they always feel tired. Sir Lauder Brunton says, "the bacillus coli seems to have a special power of producing fatigue toxins, and many people in whose intestines it exists in great abundance suffer from constant weariness and a feeling of fatigue."

SKIN MANIFESTATIONS.

The skin is usually sallow, and we may get various skin eruptions, for the toxins of chronic intestinal stasis may affect the skin by irritating or stimulating the vasomotor centres, producing such eruptions as eczema, psoriasis, urticaria and pruritus. In five cases, all women, I have seen purpura in association with intestinal toxæmia. Two of the patients have been the wives of doctors, and one, a neurasthenic case, I have watched for several years. The eruption appears in purple spots, circular in shape, as a rule, and they mostly appear on the lower extremities, and on the trunk and upper extremities to a very limited extent. They do not disappear on pressure, and are not raised above the surrounding surface, and usually fade in a few days, leaving a brownish stain. Exertion will bring on an attack. In these cases mucous colitis probably is the source of the toxins producing the purpura.

ARTHRITIC SYMPTOMS.

The joints may become affected by poisons absorbed from the intestinal mucous membrane, and rheumatoid arthritis results, for we know many poisons favour the joints, which structures seem to have a very low resisting power. It is, however, noticeable that the arthritic symptoms frequently disappear with a cessation of the mucous discharge from the bowel after a course of intestinal lavage.

APPENDICITIS AND COLITIS.

That there is a close association between appendicitis and colitis cannot be denied, and especially is this the case when the cæcum and ascending colon are chiefly affected. A localised or general catarrhal inflammation may be set up affecting the cæcum or the whole colon and the appendix may become involved by extension of the inflammation. At the present time I have several cases of mucous colitis under treatment which have been operated upon for appendicitis. They all give a history of having suffered with constipation and of having passed mucus before the appendicular attack, and in all probability if the colitis had been successfully treated no appendicitis would have occurred. Sir Frederick Treves, whose name will be always associated with the appendix, fully realised that colitis was the chief cause of failure to relieve symptoms when removal of the appendix was unsuccessful. Two years ago a lady under my care, who had been operated upon 14 years before for appendicitis, stated that she had been constipated and passing mucus ten years before the operation, and she had been suffering the same symptoms ever since. In her case the appendix was diseased and removed, but the colitis unrelieved.

The experience of a practitioner whom I know as having carefully watched cases of colitis, is very interesting as showing the connection between colitis and appendicitis. He practises in the Farnham district which, as stated by the medical officer of health, has an alarming number of cases of appendicitis. He tells me that colitis is fairly common in his practice, and gives a striking example of its association with appendicitis as shown in the following cases which were under his care:—

E. C., æt. 12 years, who had suffered from colitis for several months, had an attack of appendicitis which lasted five days, then resolved. Six months later another attack of appendicitis, very acute; operation by Mr. Edmund Owen 48 hours after first symptoms showed themselves; gangrenous appendix; died 24 hours after operation.

H. C., æt. 10 years, suffered from colitis, had an attack of appendicitis; operation within 18 hours of initial symptoms by Mr. Edmund Owen. Large swollen appendix containing small stercolith was removed; uninterrupted recovery.

S. C., æt. 8 years, suffers from colitis. These are the only three children of a mother who suffers from colitis.

APPENDICITIS A CAUSE OF MUCOUS COLITIS.

In other cases the relation is reversed, and the colitis seems to be due to chronic appendicitis. Lockwood says, "There can be no doubt whatever but that appendicitis may cause colitis. Everyone who has done many operations for the removal of the vermiform appendix has seen cases in which the end of the ileum, the cæcum, and right colon were obviously inflamed. In addition, there is tenderness along the course of the right colon, and rigidity of the abdominal wall, and evidence has been forthcoming to show that the inflammation seen upon the outside of the colon must also have involved its mucous coat, because mucus or mucus mingled with blood is seen in the evacuations."

It must be difficult to decide whether the appendix has caused the colitis or vice versa, but we do know that "the appendix is peculiarly susceptible to catarrh" (Treves), which is commonly an extension of a catarrhal inflammation of the colon, and I believe this to be a common antecedent of the milder and more chronic forms of appendicitis.

INTESTINAL SAND.

The formation of concretions in the appendix is largely responsible for the graver forms of appendicitis, which, as is well known, frequently come on without any antecedent bowel symptoms and are connected with disordered secretion of the mucous membrane of the cæcum and appendix. Owen Williams said: "These concretions called 'intestinal sand' consist of calcium salts which are

excreted by the intestinal mucous membrane, and which enter into combination with the saturated fatty acids of the food to form insoluble compounds. If formed in the appendix they may set up local inflammation, or in the colon catarrh with colicky pains."

Pain in the bowels of a colicky character is frequently complained of in colitis, and is due to spasm of the transverse or descending colon and sigmoid flexure started by local irritation. Probably the sigmoid flexure is most commonly affected by spasm, and not infrequently it is felt cord-like when firmly contracted.

Mucous Colitis a Cause of Pericolitis.

There is a class of case which we have all met with which has called forth the remark, "If the symptoms and signs were only connected with the other side of the abdomen we would call it a case of appendicitis."

We know that cases of appendicitis occur with the symptoms referred to the left side, the explanation of which I need not enter into. On the other hand, whilst we have for years recognised the condition of perityphlitis, we have not so readily accepted the fact that any part of the colon may have an inflammatory area starting in the mucous membrane and involving the peritoneum, as in perityphlitis.

Rolleston has described the case under the title of Pericolitis sinistra, and the distinctive pathological feature is the spread of infection through the submucous and muscular coats so as to involve the serous membrane. It may come on acutely as a local complication of ulcerative colitis, but as a rule it comes on insidiously after long-standing constipation, pointing strongly to an infection from the mucous surface, the inflammation of the serous coat being a secondary result. In such cases the primary morbid change is frequently one of mucous colitis, and, though severe pericolitis is comparatively rare, yet a mild and usually more chronic type is not so rare, and I think accounts for the adhesions commonly seen when the abdomen is opened for an appendicular operation.

Physical examination of the abdomen in all cases of colitis is important and instructive. It is common to find a gurgling in the cæcum, which is often distended and tender, as also the ascending and transverse colon, whilst the descending colon and sigmoid may show signs of contraction, the result of spasm of the bowel wall, though this is seldom permanent. It is advisable to make an examination per rectum whenever possible, and this must be insisted upon if blood is seen in the ejecta. Thrice within a year I have found the mucous discharge was secondary to a growth in the bowel, and in one of these cases, in which a growth in the hepatic flexure was found, the patient had passed blood and mucus in the stools for twenty years. It is important, therefore, to remember that colitis is not infrequently secondary to some local trouble, which must always be sought after.

Mucous Colitis and Movable Kidney.

It is commonly noticed that in many cases of mucous colitis there is a movable kidney on one or both sides, and dragging pains are experienced, and one author goes so far as to say this is the cause of the colitis. As the fatty structures supporting the kidneys and the abdominal muscles seem to waste and lose tone from the intestinal toxæmia this probably is the explanation of the kidney displacement.

Before any treatment is adopted we must seek for any source of poison which is likely to affect the mucous membrane of the colon. We therefore first inquire into and examine the mucous membrane of the nose, tonsils and mouth, including the teeth. We cannot lay too much stress on pyorrhœa and dental caries as common causes of the early disturbances of the alimentary canal; for although the acid secretion of the gastric mucous membrane is very often effective in destroying the bacteria swallowing into the stomach when this mucous membrane is in a healthy condition, yet should it be in a condition of catarrh with a diminution of motility, and more or less stasis of its contents, the same destruction of bacteria does not take place, and they pass on to the intestine to infect its mucous membrane.

The paramount importance of a mouth being free of septic organisms is by no means yet fully recognised by doctor or dentist, and it is sometimes a little difficult to make the patient understand how detrimental the condition of pyorrhœa really is. I am accustomed to point out that it would be very little good to attempt to cure the inflammation caused by a foreign body in one's hand if we let it remain to excite further inflammation, for on removal a cure results. They usually accept the simile, and let the dentist start his work of getting the mouth free of sepsis before, or whist I commence my treatment. Having investigated the teeth and the mucous membrane of the mouth, tonsils and naso-pharynx, we come to the stomach, and it was the fermentative changes in gastric dilatation which Bouchard believed were the causes of auto-intoxication. We have for some time considered gastric catarrh and ulceration to be not infrequently due to a bacterial invasion of the mucous membrane from the mouth in the subjects of pyorrhœa, and so may mucous colitis be also an infection from the mouth and stomach, and subsequent to gastritis and duodenal catarrh.

Treatment by Irrigation.

For several years at Plombières and Chatel-Guyon in France, and in this country at Harrogate, treatment by irrigation has been carried out with excellent results. The object is to wash away any old fæcal matter and mucus, and by so doing we get a healthier condition of the mucous membrane. At Harrogate an alkaline sulphur water is used for this purpose with excellent results. Briefly, the administration of the complete bath is carried out in the following way:—

It consists of two parts—first, irrigation of the bowel by a hydrostatic douche, given through a long rubber tube which is attached to an ordinary rectal tube. The latter is sterilised by boiling and passed into the rectum. The colon is washed out with 20 to 30 ozs. of alkaline sulphur water at a pressure of two feet, and at a prescribed temperature, usually 105° F., the patient lying for two minutes first on the right side, then on the back, and finally on the left side, during the operation. This is repeated, and the ejecta after each douche are carefully examined and reported upon by the skilled attendant. After the internal douche follows a warm immersion bath of sulphur water. When in the bath a hot douche plays upon the wall of the abdomen from a large nozzle with fine perforations, and is chiefly directed over the site of the colon. This bath not only opens out the peripheral circulation, and thus relieves the congested viscera, but is beneficial to the arthritic and nervous manifestations the result of toxic absorption.

Attention on the patient's part to moderate exercise, warm clothing, the use of a hot bottle to the cold extremities will give the greatest comfort, and by attracting blood from the splanchnic area to the periphery relieve the affected bowel; great care

in diet, avoiding all articles of food which may irritate the mucous membrane, must be strictly enforced. It is only left to say that the treatment of chronic constipation and mucous colitis by this method has been most successful, as well as educational to the patient.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Professor G. Keim, M.D., Ex-Interne of the Paris Hospitals. Subject: "Puerperal Phlebitis: its Prophylaxis and Medical Treatment."*

ORIGINAL PAPERS.

THE CLINICAL RELATIONSHIPS OF LUPUS ERYTHEMATOSUS. (a)

By G. NORMAN MEACHEN, M.D., B.S. LOND., M.R.C.P. LOND. AND EDIN.

Physician to the Hospital for Diseases of the Skin, Blackfriars, and in charge of the Skin Department, Prince of Wales's General Hospital, etc.

THE disease which we propose to discuss to-day is one of perennial interest to dermatologists and to all medical practitioners, chiefly, perhaps, because its true cause is unknown. Such a multiform affection as lupus erythematosus, or—as I prefer to call it—ulerythema (Unna) presents so many different phases and has so many relationships with other diseases, that I propose, for the purposes of this discussion, to limit my remarks more particularly to its clinical aspects and types, especially from the point of view of diagnosis.

Two principal forms of the disease are met with, the first a discrete, patchy, or, as it is sometimes called, discoid type; and the second, a more widespread, disseminated eruption, usually associated with grave constitutional symptoms. To these may be added (3) a nodular form, described by Radcliffe-Crocker; (4) the chilblain-like type, or "lupus pernio"; (5) a telangiectatic form; (6) a sclerodermic type; and (7) a form in which erythema predominates.

The first of these is by far the commonest manifestation of lupus erythematosus, and it appears usually upon the face as well-defined lesions, with a slightly raised border, a roughened surface owing to the presence of minute follicular plugs, and is curiously symmetrical, forming the well-known "butterfly patch." With the diascope no yellowish-brown nodules are seen, and a careful examination will invariably reveal some degree of atrophy of the skin. In the very earliest stages ulerythema may readily pass for a seborrhœa, in fact, one of the older names of the disease, "seborrhœa congestiva" (Hebra), shows that this aspect of the disease impressed the earlier dermatologists. It is quite common, indeed usual, for this patchy form to be associated with superficially destructive lesions upon the ears, the inside of the auricles frequently showing the peculiar orange-peel appearance described by Sir Jonathan Hutchinson.

The acute or disseminated form, first described by Kaposi, is, happily, rare. In the milder cases lesions appear upon the neck, trunk and limbs, and there is frequently some pyrexia, albuminuria and prostration. The graver forms develop bullæ or vesicles, or else the eruption becomes erysipelatous in character, and death occurs from pneumonia or tuberculosis. Cases of the latter type have been described in this country by Beetham, McDonagh, Short and others. They have also been made a special study by Pernet, under the name of "lupus erythematosus aigu d'emblée." It is cases such as these that seem to favour the view that the skin eruption is but the cutaneous manifestation of a severe toxæmia.

Lesions of the mucous membranes in lupus erythematosus were described by Dubreuilh, and Mr. T. Smith found a percentage of 28 in a series of 56 consecutive cases examined at the London Hospital. As might be expected, the mucous membranes were more often affected in the acute, desseminated type.

THE RELATIONSHIP OF LUPUS ERYTHEMATOSUS TO TUBERCULOSIS

is a question which is full of interest at the present time, since it cannot be said that any very definite opinion can be expressed one way or the other. Kaposi found that of 11 fatal cases 8 died of tuberculosis, out of 42 cases recorded by Boeck 28 presented evidences of undoubted tuberculosis, and out of 71 cases published by Sequeira there was a definite family history of tubercle in 34, and in 18 there was personal evidence of tuberculosis. Enlarged glands are commonly seen in patients who have lupus erythematosus. On the other hand, Pick found a positive reaction to tuberculin injections in only 15 out of 29 cases. Bunch has examined the opsonic index to tubercle of 10 patients with lupus erythematosus, none of whom showed any personal evidence of tuberculosis, and in 7 of these the index was normal. Sequeira obtained a positive reaction to the Calmette and von Pirquet tests in 14 cases out of 21 showing no evidence of tuberculosis. In one or two cases recorded by Pringle and Dr. Agnes Savill, respectively, acute tuberculosis has followed upon the treatment of lupus erythematosus by tuberculin injections, the cutaneous eruption clearing up meanwhile. Attempts to find tubercle bacilli in the lesions have for the most part failed, but mention should be made here of the recent work of Block and Fuchs, who have succeeded in producing tuberculosis in guinea-pigs by inoculating them with extract of fresh lupus erythematosus lesions into the peritoneal cavity; and similar results have also been obtained by Gougerot, of Paris.

The actual transition of lupus erythematosus into lupus vulgaris, made so much of by the French authors, is excessively rare. Cases have been observed, though, by several authorities in which the two diseases have been present concurrently. One instructive case may be mentioned here, that of a woman, recorded by Dr. G. Mackee, of New York, who presented a papulo-necrotic tuberculide, lupus erythematosus, lupus vulgaris, and Bazin's disease all at the same time. She was treated with tuberculin, but the lupus erythematosus lesions were unaffected thereby.

In view of such conflicting evidence it is necessary that more definite proof be brought forward before we can positively state that lupus erythematosus is a tuberculous manifestation or is of a tuberculous origin.

THE CHILBLAIN CIRCULATION.

We have all been struck with the feebleness of the peripheral circulation so often seen in cases of lupus erythematosus, and other circulatory phenomena are quite commonly seen in association with the disease, such as telangiectases, cyanosis, and Raynaud's disease. How many times do we not see cases in which it is difficult to say whether the patient is suffering from severe chilblains or from a scarring erythema, with superficial necrosis, indistinguishable from lupus erythematosus. The "lupus pernio," described by Besnier in 1888, is a variety of the disease which affects the extremities,

(a) Paper read before the annual meeting of the New London Dermatological Society, January 8th, 1913.

and also the pinna of the ear, usually commencing as a persistent erythema. Unfortunately it is often impossible in cases of lupus erythematosus upon the hands or elsewhere to diagnose the condition until some atrophy has occurred. Apparent chilblains have been observed to change into true lesions of ulerythema. Thirteen cases have been collected from the literature by Professor Hartzell, of Philadelphia, in which vascular symptoms resembling Raynaud's disease were described as occurring in direct association with lupus erythematosus, and it may be noted that the skin affection was not always present upon the hands, facial ulerythema being several times accompanied by "dead fingers" and other morbid vaso-motor phenomena.

Many cases of lupus erythematosus undoubtedly result from local causes—*i.e.*, small injuries or sudden changes of temperature, and these causes, together with an enfeebled power of resistance owing to deficient circulation, lead to a localised chronic inflammatory disturbance induced by a toxin, followed by atrophy, which we term ulerythema. Such appears to be the general trend of modern dermatological opinion with regard to the nature of this somewhat mysterious affection.

THE ASSOCIATION OF LUPUS ERYTHEMATOSUS WITH OTHER AFFECTIONS.

In view of the supposed toxic theory of the production of ulerythema, it is interesting and instructive to note the association of the disease with other disorders of the skin and other organs.

1. *Hypertrophic or atrophic rhinitis*, with or without ozæna, was noticed by Wilfrid Warde as being present in a great many cases of lupus erythematosus of the face.

2. *Erythema induratum* has been described as associated with ulerythema by MacLeod, and the same patient had previously suffered from Bazin's disease.

3. A certain amount of *keratosis pilaris* has been noticed by Warde above and anterior to the ear in association with lupus erythematosus.

4. With *erythema multiforme* ulerythema has distinct relationships, which were pointed out by Galloway and MacLeod in 1908. They showed that lupus erythematosus and certain types of erythema multiforme may be regarded as the ends of a chain in which all transitional stages may be encountered, and that they were both due to toxins of various kinds and degrees of virulence.

5. In the acute disseminated cases actual *nephritis* may be present, and this condition may be responsible for the fatal issue.

I will conclude my remarks with a few notes upon

SOME ANOMALOUS FEATURES AND PECULIARITIES OF THE DISEASE.

It is noteworthy that lupus erythematosus is exceedingly rare in children. Cases have been described by Kaposi, Jamieson, Sequeira, Schamberg, Crocker and others, between the ages of 5 and 15.

Lupus erythematosus is rarely found attacking the scalp alone without some lesions elsewhere; nevertheless, cases have been described by Stowers, Marshall, Little, myself and others. In one case of a woman, aged 54, reported by myself in 1909, the disease had denuded the whole of the posterior portion of the scalp, and the patient had lost eight children with varying manifestations of tuberculosis.

The sclerodermic type of lupus erythematosus described by Warde in 1903 is very interesting. It is simply an atrophic erythema found in patients suffering from diffuse sclerodermia of the face and hands. The rapidity with which atrophy proceeds in these cases is often striking.

Some mention must be made here of the so-called "sebaceous" type of the disease. The term is a little unfortunate, for it simply refers to the class of case, usually of the discoid form in which, on removal of the superficial scale, horny downgrowths extending into the follicles are seen. This type passes imperceptibly into the so-called "lupus-psoriasis" of Sir Jonathan Hutchinsin, which resembles a psoriasis somewhat, but is marked by atrophy and superficial scarring.

From a consideration of the above features of lupus erythematosus it is obvious that much has still to be known with regard to its true character; and whether it will ultimately be shown to be a tuberculous efflorescence or merely a cutaneous symptom of some other, yet unrecognised, morbid state the future alone must decide.

A CASE OF MALTA FEVER. (*a*)

By F. M. GARDNER-MEDWIN, M.R.C.S., L.R.C.P.LOND.

Anæsthetist to the Royal Southern Hospital, Liverpool.

ON January 20th of last year I was called to see a patient, a man, æt. 44. He was distinctly jaundiced, had a temperature of over 100, and was at the time of the visit recovering from a rigor.

The history was as follows:—Until April, 1911, the patient had suffered from no serious illness, but feeling rather run down he went, about the end of the month, to Marseilles by boat. His condition was improved by the trip, but as in the ensuing six months he had not quite regained his former tone, he decided to take a long sea-voyage.

In November, 1911, he took ship for Naples, where he remained a week, after a few days at Cannes, and then proceeded to Port Said. At Naples and Cannes he thought he had a temperature every evening, though he did not use a thermometer. At Port Said he became definitely ill, and consulted the ship's surgeon. At this time he had severe arthritis, especially in the knees and ankles; also some neuritis. Between Port Said and Colombo he became deeply jaundiced, had occasional rigors with profuse sweating, and for a time after the rigor was slightly delirious. He became so ill that on arrival at Colombo in January, 1912, he was taken ashore and placed under the care of Dr. Aldo Castellani. For several weeks he was seriously ill, and when convalescent Castellani informed him that his illness was due to an attack of Malta fever, and that the organism had been isolated from his blood.

The jaundice cleared up in a few weeks, and Castellani sent him to Italy to be under the charge of a specialist, where he had a relapse, the fever and the jaundice returning in March, 1912. Improvement was very gradual, and he returned to England in May, 1912. In June, 1912, a dental abscess and a pyorrhœa alveolaris caused a mild septicæmia, which disappeared upon the extraction of the offending molar. The gums, however, were left in a spongy condition, tender to touch, and

(*a*) *Liverpool Medico-Chirurgical Journal*, July, 1913.

bled easily, in which condition they still remained, though much improved, when I first saw him. In September, 1912, the patient went to Llandrindod Wells, and whilst there a third attack of fever and jaundice prostrated him. Recovery was slow, the fever continuing at night for some time, accompanied by profuse sweating; the jaundice remaining in a slight degree on his return to work in Liverpool. At this time he slept very badly and became nervous and excitable. On January 20, 1913, he had a severe rigor, and I saw him first on that evening. Upon examination he was distinctly but not deeply jaundiced, the whites of the eyes yellow and slightly injected, the skin a pale orange tint. Temperature 103, pulse 98, respirations 18. Tongue foul, the gums spongy and bleeding slightly, with small purpuric hæmorrhages on the mucous membranes of the mouth and lips. There were also a few very small petechial hæmorrhagic spots on the skin in various parts of the body. There was a slight irritable cough, that reminded one of the cough typhoid patients sometimes have. A few crepitant râles were to be heard in the bases of both lungs.

The heart was slightly enlarged; apex beat a little to the left; a faint blowing mitral systolic murmur at the apex. The abdomen was flat and moved normally.

The liver was enlarged; hepatic dulness extended from fifth intercostal space to nearly three fingers'-breadth below the costal margin. The spleen was easily palpable, distinctly enlarged, and felt hard. Both iliac fossæ were normal.

There was tenderness on deep pressure over the bladder.

The urine was tinged with bile and was foul and thick. He complained of frequent and sometimes painful micturition. No evidence of glandular enlargements. The calves of the legs were tender; knee jerks distinctly sub-normal and difficult to elicit. Babinski's sign was absent. The patient was perfectly clear mentally, though a little nervous and excited. There was a fine tremor of the hands.

He volunteered the statement that quinine, salicylates, and phenazonum had been tried in big doses in previous attacks without effect. I prescribed calomel, a daily saline purge, and cachets of salol and urotropin, with the idea of reducing the cystitis and possibly of producing some effect upon the bile passages. On hearing that Castellani was in London, I wrote to him, and received the following reply on January 25th, 1913:—"Mr. X had in Ceylon, Malta fever. Perhaps his blood might be examined again to see whether it is the same organism. If it is, a vaccine treatment might be tried, or, better, the new serum introduced by Professor Trambusti of Palmero." I also communicated with Dr. Bassett-Smith, whose article upon Malta fever and its treatment in England, published in the January number of the *Journal of Hygiene*, is the most valuable contribution to the treatment of the disease in recent literature. He very kindly replied to the effect that he did not recollect to have seen any case of jaundice associated with Malta fever; but that, since Italian investigators have shown that the Micrococcus melitensis has hæmolytic powers, there was no reason why it should not produce jaundice.

On January 27th Dr. John Hay was consulted, with Dr. Moore Alexander, and he suggested that, as well as bacteriological examination a chemical examination of the urine and fæces should be made, and expressed the opinion that the jaundice was probably catarrhal and possibly due to the specific organism.

Specimen of the urine and fæces were sent to Dr. Cammidge, whose opinion is summed up in his accompanying letter:—

"February 9th, 1913.—I herewith enclose a report on the specimens received from your patient on the 7th inst. As you will see, the results of the analyses show that there is a well-marked intestinal catarrh with probably secondary cholangitis and interference with the functions of the liver, but there is no evidence of any pancreatic mischief. Taking the analyses as they stand, I should make a diagnosis of 'catarrhal jaundice,' but it is possible that the intestinal condition and the state of the liver, with the consequent jaundice, may be the independent results of the Malta fever. I have examined specimens from two other cases of this disease, who had no jaundice however, and found in both a similar intestinal catarrh; so that I think it is not improbable that the cholangitis and jaundice may be a result of an infection of the bile passages from the intestine, either directly or by way of the lymphatics."

On January 28th Dr. Moore Alexander, to whom I am indebted for the bacteriological investigation of the case, made a report upon the urine and upon the agglutination reactions of the blood. From the urine an organism was isolated which gave reactions identical with those of the M. melitensis, and the serum of the patient agglutinated a laboratory strain of the organism in dilutions of 1:1,000 in three-quarters of an hour. On February 1st the patient was removed to a nursing home.

February 5th.—A blood count showed a slight decrease in the red corpuscles—10,200 whites—and an increased lymphocytosis. On this date the first dose of a vaccine of a laboratory strain was given (20 million organisms).

The result of this injection was:—

(1) Subcutaneous bleeding and bruising at site.

(2) Temperature gradually rose for three nights, remitting in the morning.

(3) Patient was distinctly more jaundiced.

The following five days the temperature fell and the jaundice decreased.

February 12th, 25-million dose.—Again for three days the temperature showed a progressively increasing evening rise, and in the six following days a corresponding fall. The patient was now obviously improving, and, though distinctly more jaundiced for two days after the injection of the vaccine, he became pale as the temperature diminished for six days. The liver and the spleen at this time began to show decrease in size.

February 20th, 50-million dose.—Temperature rose to 100.2° and remained up for two days; more local reaction than before and increase in the jaundice.

February 23rd-March 3rd.—The maximum evening rise was 99.6.

March 3rd, 75 millions.—Temperature rose following day to 102°, remaining between 97.8° and 99° for a week afterwards.

On March 8th the patient went to Bournemouth, where he caught a chill. The temperature rose for some days, but became normal on March 16th. When a 100-million dose was given by Dr. White of Bournemouth, temperature rose to 100° the next evening and remained practically normal afterwards. March 25th, 500 millions.—Evening temperature 100°, again falling to normal. Ever since the vaccine has been given regularly there has been a distinct reaction and a distinct progressive improvement.

After each injection an increase in the jaundice has been observed. In all probability the bile passages were in a catarrhal condition; and since a focal reaction has taken place, the catarrh was due to an infection with the specific organism. The present condition of the patient is such that he is able to go about his ordinary business with energy. He feels perfectly well except for the hour

or so when his temperature rises in response to the vaccine.

The liver is now normal in size, and the spleen has steadily and progressively decreased. The last dose of vaccine was 2,000 millions, and there was very little reaction.

The clinical evidence of the disease is as follows:—The undulatory type of the temperature; the enlargement of the spleen; the enlargement of the liver; the irritability of the bladder and bacilluria; insomnia; low pulse-rate; slight hæmic murmurs; cardiac dilatation; muscular tenderness; arthritic pains; sweating; subcutaneous hæmorrhages. The atypical symptom is jaundice; but since the organism can be recovered *post-mortem* from the liver and duodenum, and is hæmolytic, it is not improbable that the jaundice was due to a specific catarrhal inflammaton of the bile passages.

Dr. Cammidge reported upon specimens of the urine and fæces of the patient to the effect that the jaundice was not cirrhotic but catarrhal in nature. The condition of the fæces was similar to that of two other specimens he had examined from Malta-fever patients. The text-books do not mention jaundice as a symptom of Malta fever, and Bassett-Smith has not seen a case; but lately I have heard of three cases which were jaundiced and were said to be suffering from Malta fever. The question as to the place at which the disease was contracted is of the greatest interest. The patient was in Marseilles in April, 1911, and he felt so ill all the time afterwards that he was sent away for six months in November, 1911. Malta fever was diagnosed in January, 1912, and he had repeated attacks till January, 1913. Was he infected at Marseilles? Or at Cannes or Naples later? If the latter, what was the matter with him in the meantime? Personally, I think that he was infected in France. Certainly he had never been to Malta. Bassett-Smith says in his experience cases frequently become infected in France. To his knowledge he had no goat's milk at all. What was the source of the infection? This, of course, cannot be ascertained. But that he had Malta fever I think there can be no doubt.

Let me summarise once more:—

The type of fever undulatory; spleen enlarged; cystitis with bacilluria; specific organism found in urine; agglutination reactions to M. melitensis; blood-count typical—*i.e.*, red cells diminished, lymphocytes 50 per cent. of whites, no eosinophilia; heart enlarged, low pulse-rate, hæmic murmurs; limbs—arthritis and neuritis; excreta—condition of fæces and urine as reported, typical—treatment, reaction to specific vaccine.

There is little doubt that Malta fever is not confined to Malta. Indeed, the French term of Mediterranean fever is much more adequate, since the disease is widespread along the Mediterranean littoral—wherever, in fact, goats are kept for their milk. Several undoubted cases have occurred at Cannes, Nice, etc., among English visitors, and a few have filtered through to England, most of them being arrested in London. It is, therefore, of great importance to warn people, especially convalescents, visiting Mediterranean shores, to avoid goat's milk or cheese prepared therefrom. Dr. Eyre, of Guy's Hospital, in some correspondence on the subject, tells me that sheep also contract the disease, and that, as several of the Italian cheeses are made of sheep's milk, infection may be carried in this way also. He also tells me that he has observed jaundice in several of his cases.

I think the disease is sufficiently rare in this country to be interesting, and I wish to express my gratitude to Dr. Moore Alexander and Dr. John Hay for their valuable advice and help in the treatment of the case.

CARCINOMA OF THE RECTUM.

By K. W. MONSARRAT, C.M., F.R.C.S.Edin.,
Lecturer on Clinical Surgery, University of Liverpool, Surgeon to the Liverpool Northern Hospital.

THE operative treatment of rectal cancer often involves questions that are not easy to answer and decisions as to procedure in each case that require much consideration. This arises from several causes. In the first place, every radical procedure is attended by an appreciable mortality varying greatly with the kind of operation and the sex and age of the patient. In the second place, there is not only the operation itself to consider, but the necessity for providing an exit for fæces as useful as to position and function as the conditions will allow. Thirdly, the various operations are all attended by the risk of infection, and infection that may be virulent and dangerous. There are other factors which will lead to condemnation of, or preference for, the different operative procedures, but the above three are capital.

There are few operations that are so hampered by restrictions. In cancer elsewhere it is almost true to say the first and last question is the performance of an operation sufficiently wide of the disease; and for the most part immediate risk to life, infection, and cosmetic questions are not difficult to meet. The only parallel situation is the other end of the alimentary tract, and here justifiable operations do not raise these difficulties in the same degree.

In a discussion of the subject it is proper to consider, first, what must be removed if the disease is to be eradicated; and then to inquire what influence on procedure is exercised by the other considerations.

EXTENT OF OPERATION.

The extent of operation is determined by the extent of the disease and the directions of its spread. Cancer of the rectum is a disease of slow progress in most cases; this is a general characteristic of columnar-celled cancer of the intestine, and probably related to the comparatively slight alteration in cell type from the normal. Not only do the cells closely resemble those of the normal mucous membrane, but in their arrangement there is usually an attempt at a reproduction of the normal setting. Similar cancers elsewhere are slow to infiltrate and slow to metastasise; for example, the adeno-carcinoma of the breast.

The extension of the growth has to be traced:—

(1) In the bowel wall.
(2) In the regional lymphatics and glands.
(3) On the peritoneal surface.
(4) In other viscera.

In the bowel wall itself the edge of the growth is comparatively well defined, and the amount of intramural extension beyond the naked-eye edge is very limited.

Handley has stated that permeation in the mucous lymphatic plexus may occur very widely, even at an early stage of the disease. He bases his statement on the examination of a specimen and the demonstration of cells showing mucoid degeneration in the mucous area as far as six inches from the visible edge. In order to test whether this observation may be considered typical, I have examined by sections in series two specimens of ordinary columnar-celled cancer obtained from abdomino-perineal operations.

One specimen was obtained from a case operated on on March 23rd, 1912. The whole length of the specimen was examined from the anus to the point of section of the pelvic colon. Twenty-six blocks were cut and the sections stained by hæmatoxylin and muci-carmine. I am indebted to Mr. Handley for information as to the method of using the muci-carmine stain.

Two observations were made. In the first place, although the stain showed brilliantly the mucin of the normal mucous membrane, there was practically no mucin in the cancerous cells anywhere. Far from being characteristic of the cancer parenchyma, its absence from the latter was striking.

In the second place, the sections showed that infiltration was confined to a very limited area in the bowel wall in the immediate vicinity of visible growth, and no cells or cell-groups were seen in any of the submucous lymphatic planes away from this which had

any resemblance to the cells of the cancer parenchyma. The second specimen was derived from an abdomino-perineal amputation on June 15th, 1912. A strip of bowel wall was cut from half an inch above visible growth to the point of section of the pelvic colon. Sections of the growth itself showed typical columnar-celled cancer. In the strip, which was cut up and embedded, no traces of cancer metastasis were found.

These observations suggest that the specimen described by Handley was not typical. It probably belonged to the growths described as colloid cancer, in which mucin degeneration is universal. The malignancy of colloid carcinoma of the colon has been pointed out by Paul, and probably similar growths in the rectum are equally malignant. Fortunately, they form only a small percentage of rectal cancers, and observations on their morbid anatomy do not form a guide to procedure in the ordinary run of cases.

The lymphatic circulation of the anus and rectum has been demonstrated by Cunéo and others. There are two lymphatic planes—the mucous or submucous and the muscular; the latter anastomosing freely with the former, and also with vessels beneath the peritoneum. The whole field is divided into three areas—inferior,- middle and superior. The inferior corresponds to the skin of the anal margin, and the collecting vessels go to the superficial inguinal glands. The middle corresponds to the anal canal; the vessels here either ascend in the columns of Morgagni to join those of the superior area, or perforate the wall to go to the pararectal glands and glands associated with the middle hæmorrhoidal. The superior area drains into the small pararectal glands which lie between the fascia propria and the muscular wall, and also into the glands grouped around the superior hæmorrhoidal artery.

It is only in cancer which approaches the anal edge that attention need be paid to inguinal glands. In cancer elsewhere the lymphatic glands liable to be attacked are removed, if the rectum, along with the loose cellular tissue around, is completely taken; if the inferior hæmorrhoidals are tied as far from the rectal wall as possible, and stripped with the cellular tissue around towards the rectum; and, thirdly, if the superior hæmorrhoidal is tied high, and the fatty and connective tissue in the lower meso-colon and behind the rectum itself is stripped downwards. Operations for rectal cancer must provide access to these situations.

Cancers about the peritoneal reflexion infiltrate the wall and reach the peritoneal surface; once having done so, the disease may disseminate over the pelvic peritoneum. A case otherwise favourable for operation may be rendered inoperable by this extension. It is obviously desirable that such a condition should be discovered at an early stage of the operation and not at the end of an extensive pelvic dissection; this is a point in favour of an operative procedure which will afford an opportunity of inspecting the pelvis from the peritoneal aspect before the operator is committed to the radical operation. A forefinger of average length, 3½ inches, will just reach the peritoneal reflexion when inserted into the rectum, so that all cancers whose upper limit cannot be felt will extend to the peritoneal level. In the case of a female patient, æt. 47, whom I saw in 1907, where the growth was within two inches of the anus, an abdominal incision, made with a view to a radical operation, showed that the pouch of Douglas was studded with metastases and that a complete operation was impossible. Except for this, the local condition was favourable for amputation. Therefore, even in cancers which do not appear to reach the level of the peritoneal reflexion, it is wise to see the condition of affairs from above before a radical operation is proceeded with.

Visceral metastasis is fortunately late in most cases; it is common to meet with patients who have had symptoms for six to twelve months who yet present no signs of secondary growths. The lateness of metastasis has been shown over and over again by patients living one, two and three years after a palliative colostomy. It is safe to say that one need not be deterred from operation by fear of secondary growths in cases which are met with reasonably early. Of course, they should be looked for, and in one of the three fatal cases in the group I report they appear to have been overlooked. He died suddenly four months after a complete operation, and a *post mortem* was obtained; the liver weighed 82 ounces and contained many large secondary nodules, and there was one also in the right lung.

From the point of view, therefore, of the habit of growth, the following considerations influence the question of operation:—

(1) There is no necessity to remove a long length of bowel wall above the visible disease as routine.

(2) General metastasis is late.

(3) A careful pelvic dissection is necessary, including all the cellular tissue associated with the bowel itself, and extending upwards in relation to the superior hæmorrhoidal and laterally in relation to the inferior hæmorrhoidals.

(4) An early inspection of the pelvic peritoneum is advisable.

PROVISION OF ANUS.

The second consideration I wish to discuss is the position of the final anus. The provision of a controlled anus is a point to which a great deal of importance has been attached. It is probably true that the effort to provide this has sometimes risked return of the disease. Most rectal cancers that one meets with reach to within two inches of the anus, and under such circumstances I believe it is impossible to remove the growth and its surroundings sufficiently widely, and at the same time leave a satisfactory controllable anus. Of course, the situation of the growth will have a great deal to do with deciding whether this attempt should be made, but even under favourable circumstances the result is somewhat disappointing. In the following instance, for example, anatomical restoration is good, but function is indifferent.

A female patient, æt. 38, of poor physique, presented an early fungating cancer growing from the anterior wall of the rectum at its upper limit. The operation was performed on August 9th, 1911; a parasacral incision was made, and a dissection was carried out sufficient to allow a considerable loop of rectum and pelvic colon to be exteriorised. Nothing more than this was done at the time, as the patient behaved badly under the anæsthetic. It was subsequently treated as one may treat a colon cancer: the mass was cut away on the second day, the spur subsequently destroyed, and the opening closed. At the present time she is in good health and has put on a good deal of weight, but is troubled by great difficulty in emptying the bowel; there is a satisfactorily wide opening, but fæces lodge there, and the bowel appears to be incapable of propelling them onwards. Although, therefore, she has an intact anal sphincter and the continuity of the bowel is restored, constipation is a very real trouble, and what she herself asks is to return to the artificial anus.

If it is decided that no attempt should be made to save the sphincter, the question then arises as to the best position for an artificial anus. The proper position for an uncontrolled anus is in the inguinal region. The uncontrolled anus in the perineum or sacral region is a misery to the patient—out of sight, difficult to keep clean, and unsuited for the wearing of a plug, it makes life a burden to a far greater extent than an inguinal anus.

In a recent abdomino-perineal amputation (*a*) in which I intended to leave the anus, but judged it unwise during the operation, the patient was left with an uncontrolled perineal anus: I added to her comfort later by an inguinal colostomy. A little mucus comes from the perineal opening, but does not inconvenience her. Her inguinal anus is well managed by a plug and belt, and I believe she is much better off than if the fæces were coming by the perineum. As far as the position of the anus is concerned, procedures which are terminated by an inguinal anus are preferable to those which are completed by leaving an uncontrolled anus elsewhere, and this point is a guide as far as it goes in choosing a method of operation.

(*a*) *Liverpool Medical Journal.*

MORTALITY.

The third question influencing the choice of operation is that of mortality, and all records show that it is a serious one. The deaths are due to shock and to sepsis. There were three deaths in the thirteen cases of radical operation which I am reporting. Two were due to infection; the other I have already mentioned, in which death occurred from syncope four months after operation, secondary growths being present.

There is no doubt that the mortality from abdomino-perineal amputation is high (Abbe quotes Kraske as having had four deaths in ten cases), but there is a great difference in tolerance between men and women.

The two cases fatal from infection were men. The one was aged 63; operated on on December 15th, 1909. The growth was in the rectal ampulla, within reach of the finger but not encroaching on the anal canal. A median abdominal incision was made, the pelvic colon was mobilised, the peritoneum in the pelvis incised, and the rectum freed from the bladder in front and from the hollow of the pelvis behind. The superior hæmorrhoidal was tied at some distance from the bowel, but neither in this nor other cases have I been able to demonstrate the anastomotic branches between superior hæmorrhoidal and left colic, to the importance of which Sudeck and Tuttle have drawn attention. I am not convinced of the possibility of doing so in a meso-sigmoid loaded with fat. The patient was then placed in the elevated pelvis position and the rectum removed by perineal incision, with preservation of the sphincter by Ball's method. The gut was easily drawn down, about nine inches removed, a Paul's tube ligatured in the stump, and the edges of the perineal incision brought together around it. The terminal four or five inches of the colon sloughed, septicæmia supervened, and the patient succumbed to this on the fifth day.

The other fatal case was a male, æt. 54, operated on in a cottage hospital in Cheshire. The carcinoma was of the ampulla. The pelvic colon was divided and the proximal end brought out in the inguinal region. After freeing the lower part of the rectum from within, the whole of the bowel below the division was removed through a perineal incision. The patient did well for a time. The perineal wound progressed favourably, but the inguinal wound became infected and there was little resistance to this. He died suddenly a little more than three weeks after the operation, and at the time of his death his doctor tells me the perineal wound was practically healed, but there was a cellulitis of the abdominal parietes around the inguinal anus. The man was a pronounced alcoholic and stout. It would probably have been better to have declined operation in his case. A mortality of 3 in 13 cases submitted to radical operation is high. Two of these might have been eliminated by a more conservative selection of cases; the third was directly due to sloughing of the colon. The freeing of the pelvic colon was too thorough. The House Surgeon's notes say that about 9 inches of rectum and colon were resected after delivery through the anus; to obtain this the vascular supply of the colon was evidently endangered. Such a mortality, however, prejudices one against the abdomino-perineal operation in males.

SELECTION OF OPERATION.

In spite of much recent discussion, the choice of operation for rectal cancer is in an unsettled condition. It is becoming gradually possible, however, to narrow the issues. If I venture to answer some of the questions, it is more from a desire to propound these questions than from the idea that my own experience enables me to answer them dogmatically.

Is it necessary to remove the whole of the rectum and a considerable part of the pelvic colon in every case of rectal cancer?

Mr. Sampson Handley's discovery of metastasic cancer cells at a considerable distance from the visible growth has not been corroborated by others as far as I am aware. He states that permeation of the mucous lymphatic plexus as a factor in dissemination is probably limited in effectiveness by the habitual degeneration of the cancer cells in this situation. He draws the conclusion, however, from his researches, that a long length of bowel should be removed, including the sphincters. Clinical experience is against this doctrine. If it were true, one would expect morbid anatomists to tell us of the frequency of secondary cancer masses in the colon at a distance from the primary seat of the disease. I believe that, on the contrary, this is an extremely rare discovery. The disease does extend in the long axis of the bowel, but in direct continuity with the primary growth. If the cell groups which he described are never effective in producing secondary growths, then no importance attaches to them as far as the surgeon is concerned. I have already given reasons for believing that the specimen he described was not typical. Pathology, therefore, does not impose the duty of removing the whole rectum and a length of bowel above in every case.

Should the abdomen be opened in all cases? I think this should be answered in the affirmative: on the one hand, because of the opportunity it affords of inspecting the extent of the disease; on the other, because I believe in the inguinal anus as routine when the sphincteric apparatus is not preserved.

What limits are to be placed on the effort to re-establish the normal method of defæcation after resection or amputation? The free mobilisation of the colon which seemed to promise so much from this point of view has proved disappointing. I believe that there is considerable risk, not only of disappointment, but also of danger, in the proceeding. It appears to be a very common experience to have sloughing of the end of the mobilised colon occur, at any rate when an operation for high cancer is completed by bringing the colon down to the perineum. Are the results obtained worth the added risk? Apparently not; it is safe enough in a low cancer to free the bowel sufficiently for excision and fixation in the perineum, but a high cancer operation had better be completed by a temporary sacral anus if a complete amputation with inguinal anus is not done. It is to be remembered that even a small amount of sloughing of the end of the bowel is enough to spoil the functional result; a stricture forms which will give patient and surgeon much trouble.

There is much to be said for the view that only in low cancers in which there is a margin of two inches between the anus and the edge of the growth is it wise to attempt restoration of the normal anus by bringing the end of the colon down to the perineum.

If it is admitted—

(*a*) That it is not necessary to remove a long length of bowel above the growth;

(*b*) That the mortality of the combined operation in males is excessively high;

(*c*) That the position for a permanent uncontrolled anus is inguinal;

(*d*) That the abdomen should be opened in all cases,

one is in a position to discuss choice of operation, making two distinctions: on the one hand, between males and females; on the other, between low cancers and high cancers.

In a male with low cancer the abdomen is opened and the pelvis inspected. If the sphincter is to be preserved, nothing more than this is done here; if the sphincter is to be sacrificed, the colon is fixed unopened in an inguinal wound. The dissection of the growth is carried out from the perineum. If the sphincters have to go, the operation is an amputation, including the anus. If the sphincters can be preserved, the operation described by Ball in the last edition of his text-book on "Diseases of the Rectum" is suitable. I have carried out the method in five cases; one was one of the fatal cases already mentioned, four survived, but I have information as to the functional result in two only: one, a female, operated on four years ago, with perfect control and no recurrence; the other a male, operated on a year and nine months ago, with control generally complete but occasionally uncertain and no recurrence. One detail recommended by Ball is inadvisable—that is to say, to leave the ligature in place on the end of the gut at the anus for a few days. I did this in my first case, and the

patient suffered from extreme flatulent distension of the colon on the second day. If the sphincters are removed, the end of the gut is brought out at the site of the anus, or farther back, and the patient's comfort increased by opening the colon fixed in the inguinal region.

In a male with high cancer the abdomen is opened for inspection; a post-anal incision is then made and the coccyx removed; the gut is then freed sufficiently to bring out a loop, together with the adherent fat glands and cellular tissue. This mass is left *in situ* for three days and then cut away, leaving an artificial anus, which is subsequently closed after destroying the spur. The spur requires very complete destruction. In a female patient with low cancer the abdomen is opened and a pelvic dissection is carried out. If the sphincter can be preserved, the removal is completed by Ball's operation; if the sphincter cannot be preserved, the colon is cut across and the proximal end implanted in an inguinal wound, the whole of the bowel below being removed by the perineum. In the female with high cancer the abdomen is opened and the growth freed; the mass is then delivered through a sacral incision and treated as one does a colon cancer. If the growth is at all advanced, it may be better to amputate completely, leaving an inguinal anus. I have performed the combined operation in six cases—four women and two men; the four women recovered, the two men, as already stated above, succumbed.

In the discussion on rectal cancer at the recent meeting of the British Medical Association in Liverpool, Professor Armstrong recommended the performance of the combined operation in two stages to save shock; the first stage an abdominal dissection freeing the colon and rectum, the second stage a perineal operation delivering and fixing the colon below. I adopted this plan in a case of low pelvic colon cancer which could not be delivered through an abdominal wound. The interval between the first and second stages was attended by a great deal of pelvic pain, and the condition at the second operation showed that the reaction around the freed colon, undrained in the depth of the pelvis, may make this part of the proceeding difficult and dangerous. The condition of the patient in the interval, and the state of affairs found at the second operation, have dissuaded me from adopting the method again.

Of the invagination methods associated with the names of Maunsell and Weir I have no experience; I have never met with a growth which, when freed along with its surroundings, seemed capable of being invaginated. I believe my colleague Mr. R. W. Murray has had a successful result with this method.

I have incidentally mentioned all the thirteen cases on whom I have performed radical operation with the exception of two, both sacral resections. One, a male, aged 30 years, made a satisfactory recovery, but is known to have had recurrence of the disease in six months; the other was a female, and is now alive and free from recurrence seventeen months after the operation.

OPERATING THEATRES.

BOLINGBROKE HOSPITAL.

NEPHRECTOMY FOR RUPTURED KIDNEY.—MR. SWAINSON operated on a female child, æt. 6, who had been admitted with the following history. She fell down five wooden steps at 10.30 a.m. one morning. She was put to bed by her mother. At four a.m. on the following day the child passed about four ounces of blood from the urethra; between the accident and this time she had vomited four times. A doctor was now sent for, who kept the patient under observation until the evening. The child was admitted to the Bolingbroke Hospital at 3 p.m.—that is to say, on the evening of the day following the accident. The girl complained of abdominal pain and was somewhat blanched. The left renal region was tender, and palpation of the loin was resisted owing to rigidity. Mr. Swainson decided to operate. Under chloroform a distinct swelling could be felt on bimanual palpation of the loin. The child was placed on the right side and the left kidney explored by an incision below and parallel to the last rib. There was considerable extravasation of blood, and the kidney was completely divided into three portions held together slightly at the pelvis, which was itself torn. It was thought necessary to remove the whole organ, and this was carried out. The wound was sewn up and drained by a tube and a small piece of gauze. There was some shock, which was treated by continuous saline infusion per rectum.

Mr. Swainson remarked that injuries of the kidney were difficult to diagnose from other lesions of the abdominal organs in their early stages. Shock and rigidity were present in most cases; the degree of shock afforded no certain guide to diagnosis, as it bore no regular relation to the extent of injury. It was sometimes necessary to explore the abdomen to treat or to exclude the existence of ruptures of the hollow viscera. In the present case, which was not seen for some time after the injury, the symptoms were definitely localised to the renal region, and the hæmaturia pointed to a lesion of the urinary organs. In hæmaturia of slight degree cystoscopy had been found useful in localising the seat of the mischief; blood, for instance, might be seen coming from one ureter. Mere hæmaturia was not sufficient indication for operation. In the present case a definite renal tumour was cut down upon.

The patient made an uninterrupted recovery. The plug of gauze and tube were removed on the second day, and the wound was painted with tincture of iodine. The wound was completely healed in five weeks. The day after operation sixteen ounces of urine were passed, and the average amount passed subsequently to the operation was eighteen ounces per day, but the smallest amount in one day was eight ounces. The child had a little bronchitis, but this was explained by the fact of her recently having had whooping cough.

The ruptured kidney is now in the museum of the Westminster Hospital. It was interesting. Mr. Swainson thought, from the fact that it contained several infarcts; it was not quite clear how these had arisen. There were no cardiac lesions detected on examination.

TRANSVERSE FRACTURE OF THE PATELLA TREATED BY WIRING.—The same surgeon operated on a man, æt. about 30, who was a fireman and gymnastic instructor. The patient slipped, but did not fall, in running to catch a bus, and he felt something "go" in his knee. On examination, a fractured patella could easily be detected by palpation. At the operation a semi-lunar incision was made at the outer edge of the patella and the flap thus formed turned inwards. Blood clot was removed from the joint and the fractured surfaces of the patella scraped with a sharp spoon to remove clot and torn aponeurosis. A hole was drilled through each fragment obliquely, passing short of the cartilage, and a silver wire passed through the holes thus made, the ends of the wire being twisted together in front of the patella so that the fractured surfaces were brought firmly into apposition. The flap was then replaced and sewn in position by interrupted sutures of silkworm gut.

Mr. Swainson said he would point out that there were two kinds of fractured patella—fractures by direct and by indirect violence. Fracture by indirect violence, as the one just operated on, was transverse in direction, the fragments tended to be separated, and the torn aponeurosis of the quadriceps extensor cruris got between the fragments, with the result that union was usually fibrous and not bony. For this reason it was now the custom to operate on most cases of fractured patella so as to ensure bony union. In fractures by direct violence the line of fracture might run vertically or in a stellate manner, and the fragments being close together bony union could usually be relied on if expectant and not operative measures were made use of.

DR. JOSIAH WILLIAM WALKER, M.D., L.R.C.S., left estate of which £18,217 is net personalty.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

MEETING HELD THURSDAY, JANUARY 8TH, 1914.

The President, DR. W. S. A. GRIFFITH, in the Chair.

SPECIMENS.

MR. GORDON LEY showed a specimen of *Fatty change in a Fibromyoma of the uterus*. The specimen had been removed from a patient 54 years of age. The tumour had given rise to hæmorrhage, and the uterus was removed for that reason. The tumour lay in the posterior wall of the uterus. It was encapsulated, and appeared to be a fibromyoma with yellow streaks and yellow homogeneous areas scattered throughout it. Microscopically, it showed a fibro-muscular tissue surrounding numerous spaces containing fat. There was no degeneration of the cell elements. Mr. Ley pointed out that the fat was situated in the cells of the connective tissue, and that the globules of fat were large contrasting with the small fat globules seen in the muscle cells in calcareous impregnation and hæmorrhagic necrosis of fibromyomata. He was of opinion that the tumour was either a condition of fatty metamorphosis of the fibrous stroma of a fibromyoma or a fibro-myo-lipoma. From the arrangement of the fat in the tissue and from the absence of young fat granule cells, he concluded that the former interpretation was probably the correct one.

The specimen was referred to the Pathology Committee, who gave it as their opinion that the tumour was a fibromyoma which had undergone fatty denegeration.

DR. EDEN: A case of *chorion-epithelioma of the uterus with bilateral lutein cysts of the ovary*. The case occurred in a married woman, æt. 27, who was admitted to the Chelsea Hospital for Women. The uterus was considerably enlarged, and after some days the cervix was dilated on account of hæmorrhage and the uterus evacuated of a well-marked hydatidiform mole by vaginal hysterotomy. At the time there was an area of suspicious thickening felt near the fundus, but it was felt advisable to do nothing further, as the patient has lost very considerably. Convalescence was normal. She was then sent to a convalescent home and requested to report herself later. Six weeks afterwards she returned to the hospital and was examined. The uterus was normal, but there was now a soft swelling in the region of the left ovary. There was no discharge from the uterus. A fortnight later the swelling in the left ovarian region had increased considerably, and a smaller cystic mass could be felt on the right side which was not detected at the first examination. Abdominal section was performed and two simple ovarian cysts found, together with a somewhat irregular uterus. Supra-vaginal hysterectomy was performed, and on opening the uterus masses of soft red growth were found. Sections showed typical chorion-epithelium deeply invading the uterine wall. Lutein cysts were present in the ovaries. The operation, which was performed two and a half years ago, was successful, and the patient has had no return of the disease up to the present time.

DR. EDEN remarked on the total absence of hæmorrhage or discharge after removal of the vesicular mole, although a malignant growth was present in the uterus. Attention was drawn to the rapidity with which the ovarian cysts grew, and to the complete cure by operation which had resulted.

Remarks were made by Dr. WILLIAMSON and Mr. MALCOLM.

THE PRESIDENT (Dr. W. S. Griffith) reported a case of

PRIMARY EPITHELIOMA OF THE VAGINA TREATED BY RADIUM.

Mrs. A., æt. 67, one child at 30, no miscarriage. Menstruation always scanty, ceased at 50. Health generally good, but has recently suffered from glaucoma and cataract in both eyes. Weight average. October, 1912: Mucous leucorrhœa first noticed, sometimes tinged with blood, but there has been no hæmorrhage nor any pain. June 3rd, 1913: Examined under anæsthetic by Dr. Griffith, who found a warty papillary growth of the posterior fornix about 1½ in. in length by 1 in. in breadth, apparently involving the whole thickness of the thin senile vagina, but the rectal wall was quite free. The cervix was senile and healthy. A portion was removed and found to be squamous-celled epithelioma. Treatment by radium by M. A. E. Pinch, F.R.C.S., at the Royal Institute: June 16th, 25 mg., screen 1 mm. silver, 6 hours; June 17th—20th, 50 mg., screen 2 mm. lead, 6 hours each day; July 25th, Mr. Pinch found that the greater part of the growth had disappeared, leaving a small patch the size of a sixpence, and gave another course of radium; July 25th—29th, 25 mg. radium screen, 1.5 mm. lead, each day for 6 hours; October 14th, Dr. Griffith examined and found no trace of disease, the vagina was smooth and soft, but a little more contracted than in June.

Dr. GRIFFITH reported this isolated case for two reasons—because primary epithelioma of the vagina is a comparatively rare disease, and because of its anatomical relations, treatment by operation is not very satisfactory, whether by partial excision, as in C. H. Robert's case, by excision of the whole vagina, (Olshausen), or by excision of the vagina and uterus (Amann). He hoped to be able to report the further progress of his case to the Section, and suggested that all gynæcological cases treated by radium, and of which accurate details were obtained, should be reported.

References were then made to the literature of the disease.

Remarks were made by Dr. MACNAUGHTEN JONES, Dr RUSSELL ANDREWS, Dr. BLACKER, and Dr. LOCKYER.

Dr. RUSSELL ANDREWS brought forward a case of

HÆMATOMETRA WITH ABSENCE OF THE UPPER PART OF THE VAGINA.

A patient, æt. 22, who had never menstruated, complained of abdominal pain recurring every month for the last eight years. For the last few months this pain had been sufficiently severe to keep her in bed. For a long time—she did not know how long—she had had a tender swelling in the lower part of the abdomen. This swelling reached about three inches above the pubes. The external genitals were normal, but the vagina was not more than an inch long. On rectal examination, a tumour, the size of a large pear, could be felt in the position of the uterus. No distinction between body and cervix could be made out. The abdomen was opened, and the uterus, which was five inches long, distended with blood, was removed, together with a left-sided hæmatosalpinx and small ovarian tumour; the right ovary, which was normal, being preserved. The patient made an uninterrupted recovery. No trace of the external os could be found, and the vagina seemed to be completely absent except for about an inch at the lower end. Dr. Andrews considered that the removal of the hæmatometra and hæmatosalpinx by the abdomen was better treatment than drainage from below, with an attempt at making a new vagina. The operation of grafting would be a very difficult one in a case where the upper part of the vagina was wanting.

Remarks were made by the PRESIDENT.

Dr. CUTHBERT LOCKYER introduced a

CASE OF DOUBLE OVARIOTOMY WITH UNUSUAL POST-OPERATIVE PHENOMENA.

This case occurred in the practice of Dr. Hamilton Whiteford, of Plymouth, who performed the operation, and whose clinical account of the case Dr. Lockyer read in full before the Society. The patient was aged 78, and in August, 1910, Dr. Whiteford operated for a strangulated right femoral hernia. The sac was so badly infected that the pelvic colon was opened and drained through the lower border of the right rectus muscle. The patient recovered, but was left with the colostomy and a large protrusion in the femoral region. Early in 1913 the lower abdomen began to enlarge, and in June of the same year was enormously distended and presenting a fluid thrill. It was decided

to make a small incision into the tumour mass and five pints of creamy dermoid fluid escaped as well as hair. Five hours later an abdominal section was performed, and a large dermoid cyst of the left ovary removed with great difficulty, owing to adhesions. There was a smaller cyst of the right ovary. Both cysts contained more or less typical dermoid elements, hair, bone, skin, etc., together with more solid material of a fibrous nature. The fundus uteri was removed at the time of the operation. The abdominal wound healed well, but on the thirteenth day after a tumour was found in the left iliac fossa. This was incised through the left rectus muscle and simulated a cyst of the left broad ligament. It could not be removed. Five ounces of thin blood-stained fluid were withdrawn on the fifteenth day. The fluid re-collected in the pelvis, and on the twenty-first day 46 ounces were aspirated, on the twenty-eighth day 20 ounces were withdrawn, a total of 51 ounces in three weeks. Examination proved that urea was absent. On the fortieth day thorough drainage per vaginam was established. The patient gradually sank, and died at the end of four months. *Post-mortem* examination showed small masses of hard, white growth in the pelvic floor. The left inferior quadrant of the abdomen was everywhere shut off by adhesions. There was no general hydroperitoneum or visceral deposits. There was no injury to bladder or ureter. Microscopical examination of the portions of the cyst walls show that the case is one of bilateral perithelioma. The masses in the pelvis, whether secondary or the remains of the primary growth, would account for the curious clinical feature of continuous local secretion of large amounts of fluid by the peritoneum. The specimens were referred to the Pathological Committee, who agreed with Dr. Lockyer that they were dermoid tumours, in which definite peritheliomatous changes were present.

Mr. DOUGLAS G. REID (Cambridge) read a paper (with lantern slide demonstration), chiefly dealing with the

GENITO-MESENTERIC FOLD OF PERITONEUM,

which he has described in the fœtus and demonstrated in adults. He pointed out that the terminal part of the ileum may be connected to the abdominal wall by (1) this fold, (2) the "bloodless" fold of Treves, or (3) adhesions (common both in the fœtus and adult). He discussed the question of intestinal flexures and showed how these might become acute. It was important to distinguish between (1) permanent flexures and (2) those which had no real claim to be regarded as other than temporary.

The genito-mesenteric fold appeared after the fourth month of fœtal life, was attached along definite lines and at first free, as regards adhesions. Later the ileum, appendix, cæcum, etc., might adhere to it and through it be very closely bound to the right ovary and Fallopian tube. It was very common for the meso-appendix to adhere to this main (genito-mesenteric) fold. This fold was of importance in relation to the spread of infection or inflammation from the bowel to the ovary and tube or in the opposite direction. An important point was the presence of lymphatic nodes in the fold.

Surgically the fold was of importance for many reasons. It determined adhesions which, besides lowering the root of the mesentery, would act as barriers restricting the spread of inflammation. It was the commonest cause of a retro-colic position of the appendix. It would complicate operations for the removal of the appendix, etc., produce hernia, displace viscera, and possibly determine strangulation of the bowel. Variations in the position and relations of the appendix at various stages of cæcal torsion were considered and were of importance. The action of the pelvic colon in producing adhesions and obliterating the genito-mesenteric fold was discussed. Thus the fold was not so common in the adult as in the fœtus. The origin of Jackson's membrane was considered. The retro-pancreatico-duodenal fossa, and other fossæ, folds, and adhesions, were demonstrated, as was the supra-adhesion foramen. Their importance was considered, especially in relation to the formation of "ready-made abscess cavities" and operations upon the stomach. Practically all the points were illustrated with photographs.

Remarks were made by Professor WATERSTON and Dr. MACNAUGHTON JONES.

Mr. REID replied.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 8TH, 1914.

The President, DR. DAVID WALSH, in the Chair.

CASES.

DR. ABRAHAM: Lupus vulgaris on face; seen 20 years ago; treated by scraping and acid nitrate of mercury. Ten years' freedom; returned other side of face; treated by Finsen rays, etc.; no improvement. Saw Dr. Abraham again, who re-scraped with ten years' relief. Had now recurred for third time.

DR. MEACHEN: Lupus erythematosus almost entirely confined to scalp.

DR. SAMUEL: Erythema iris; three weeks' duration; on arms, legs and inside mouth, each patch having a bulla; the nasal mucous membranes became affected. Nearly well in three weeks.

Dr. NORMAN MEACHEN then read a paper introducing for discussion the subject of

LUPUS ERYTHEMATOSUS,

which will be found under the heading of "Original Papers," page 59. In the discussion that followed Dr. P. S. ABRAHAM remarked that he was not yet satisfied as to the relationship of tuberculosis to lupus erythematosus. One of the worst cases he ever had to deal with occurred in a young woman, the subject of heart disease, the face and scalp being markedly affected with lupus erythematosus. The eruption spread rapidly and the patient died, multiple abscesses in the lungs being found *post mortem*. Such a case as this was certainly in favour of the toxic theory of the disease.

Dr. ALFRED EDDOWES said that as his experience increased he more and more inclined to the view that tuberculosis often played an important part in the production of the disease under discussion, but we must not ignore other morbid processes. Moreover, looking at the acutely inflamed patches with a spreading border almost like that of erysipelas, he was strongly disposed to look for a local cause—a formation of an irritant in the epidermis, which was probably absorbed and damaged the vascular tissue beneath. Nerve reflex also probably played a part. In support of his views, he referred briefly to several cases occurring in his own practice: (1) A case seen by several members present of a young girl with acute lupus erythematosus of face and scalp. The disease on scalp was peculiar in that the girl's auburn hair fell out as the erythema spread centrifugally to be replaced soon by black hair which in about two or three months returned to its normal colour. The patient has improved since removal of tonsils and operation on adenoids. She is no longer a mouth-breather. There was a strong family history of tubercle. (2) A case of acute œdematous lupus erythematosus of face. No history of tubercle, but father died of pernicious anæmia. The patient is anæmic. (3) A condition indistinguishable from lupus erythematosus on the face of a patient who became syphilitic eight years ago. Improvement under treatment for syphilis. This was lupus erythematosus upon a syphilitic base—or it was a dermatosyphilide imitating it. Why not a syphilitic lupus erythematosus? (4) A child was exposed to great cold in a perambulator, brought home and placed too near to a hot fire. A permanent erythematous patch appeared upon the cheek which had been most exposed to the heat of the fire. When the inflammation disappeared, a slight scarring of the affected area could be made out. This child was liable to attacks of serious vomiting, producing extreme exhaustion, and a fact which proved that these attacks were of intestinal origin was that they immediately

eased if a brisk purge could be got through the bowels. No tubercular history. (5) A healthy young man had a patch of erythema over the point of emergence of the submaxillary nerve. He had exhausted himself by work and late hours in the London season. No neurotic or tubercular disease in family. The exciting cause was looked for and found to be the eruption of the lower wisdom tooth on that side of the jaw. The speaker considered that by carefully noting causes of other erythemata than lupus erythematosus we should probably throw great light on that disease itself. Acting upon his theory that there was a toxin produced locally he had adopted the use of local remedies containing a large proportion of alcohol—with which the surface was cleaned and dressed. The plan was promising.

Dr. W. J. MIDELTON mentioned a case in which lupus erythematosus was associated with rheumatoid arthritis. With regard to the use of tuberculin, he was in favour of large doses, rapidly increased, for he felt sure that more boldness was necessary in the administration of tuberculin.

Mr. T. P. BEDDOES remarked upon the similarity of the digestive flush seen in dyspeptics to the typical "bats-wing" area affected by lupus erythematosus. He was much impressed by the fact that in many cases of death in the acute, disseminated form no definite cause had been found at the autopsy. Might not the fatal result be due to the stress action of the skin, as in severe burns, or in renal disease from suppressed action of the kidneys?

The PRESIDENT (Dr. David Walsh) said that lupus erythematosus was one of the reproaches of dermatology. In spite of the careful study that had been devoted to that affection, the comparative simplicity of its pathology and the general innocuousness of its processes we nevertheless were powerless in many instances to deal with it effectually. He cited the case of a clergyman of fine physical and mental development, whose career was ruined by a lupus erythematosus that finally involved the whole face. A result of that kind revealed the width of the field before the dermatologist. The disease was of the nature of a localised cutaneous inflammation due probably to a toxin, or more likely to manifold toxins. Its occasional association with nephritis suggested that the stress of eliminatory irritation might be shifted from the kidney to the skin, although it was not easy to determine why it should assume certain constant characteristics in the cutaneous form. Lupus erythematosus might, in short, be regarded as a symptomatic disease in which the brunt of some toxic mischief fell mainly on the cutaneous blood-vessels, but the precise determining conditions were obscure. In some instances he had found cardio-vascular disease which he regarded as a predisposing cause. Certainly the chilblain circulation of Hutchinson appeared to be often a contributory condition. The occasional difficulty of diagnosis was shown by a case under his care in which a watchmaker suffered from an extremely chronic dermatitis of the right hand, which was treated as syphilitic by half-a-dozen leading dermatologists. The speaker adopted a similar diagnosis for some time, but eventually recognised it as a lupus erythematosus. A patient under his care at the present time showed an interesting condition. She was a married woman, 25 years of age, of good family and personal history. She had several pale nodules about the size of hemp seeds about the nose and cheek, of some three months' duration, with an infiltrated gummatous tuberculide nearly in the centre on the upper outer left arm, and two absolutely typical lupus erythematosus patches, one behind the right ear and the other on the rim of the left ear. A Von Pirquet test was positive. She was treated with tuberculin T.E., increasing to 2 c.c. At the end of two months the nodules and the gumma on the arm had disappeared without scarring, while the patches on and behind the ears were rapidly involuting, one under a scab. The case was of interest as showing that tuberculin could affect some skin lesions indistinguishable clinically from lupus erythematosus. Personally, he regarded tuberculosis as one of various factors in this interesting skin affection.

Dr. H. C. SAMUEL referred to the use of menthol in grain doses in the acute cases. He knew of two cases in which acute pulmonary tuberculosis had developed in the course of lupus erythematosus. He sketched the treatment which had been adopted, expressing the opinion that more advantage might be taken of the method of ionisation.

Mr. DENNIS VINRACE said that low vitality, debility, cardio-vascular deficiency and malnutrition gave proneness to the disease. It had been objected that lupus erythematosus was of tubercular origin where certain tubercular tests proved negative, but it was fully conceivable in these instances that the general tuberculosis had been arrested leaving the lupus erythematosus to progress. Lupus erythematosus of the auricle was favoured in its development by the low vitality of its tissues.

ULSTER MEDICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 8TH, 1914.

The President, MR. A. B. MITCHELL, F.R.C.S., in the Chair.

The CHAIRMAN referred in sympathetic terms to the loss which the Society had recently sustained by the deaths of Dr. John Gorman and Dr. J. C. Ferguson, both of whom had been connected with the Society for many years. He proposed that the Secretary be instructed to convey to Mrs. Gorman and Mrs. Ferguson the deep sympathy of the profession in Belfast. This was seconded by Professor Lindsay and passed in silence, all those present standing.

Dr. J. D. WILLIAMSON read notes of a case of acute yellow atrophy of the liver in a child who had been admitted to the Ulster Hospital with the diagnosis of meningitis. The blood of the patient gave a positive Wassermann. A *post-mortem* examination with the microscopic and macroscopic appearances of the liver confirmed the opinion which Dr. Williamson had formed during the five days during which the child was under his care in hospital. The relation between syphilis and acute yellow atrophy was raised, but it was felt that no definite opinion could yet be expressed upon it.

Dr. H. L. M'KISACK read a paper on the "Differential Diagnosis of Hysteria from Other Nervous Affections," and by means of tables thrown upon the screen contrasted the signs and symptoms indicative of each.

Mr. J. L. RENTOUL read a paper upon "Treatment by Tuberculin," based upon his experience in upwards of 150 cases which he had carefully observed from day to day and recorded. He set himself to explain why pulmonary tuberculosis did not respond to treatment by tuberculin, whilst the so-called surgical tuberculosis—a term of which he strongly disapproved—generally did well. This depended on some inherent property in the tissue and not upon the infection or the kind of tuberculin used in the case. These papers were discussed by many of those present, and the readers afterwards replied.

LIVERPOOL MEDICAL INSTITUTION.

AT the annual meeting held on Thursday, January 15th, 1914, the following list of Office Bearers and Members of Council was adopted :—

President, *Edward William Hope; Vice-Presidents, Thomas Bushby, W. B. Warrington, *R. J. M. Buchanan, and *Alexander Stookes; Treasurer, R. J. Hamilton; General Secretary, Frank Hugh Barendt; Secretary of Ordinary Meetings, *John Hay; Secretary of Pathological Meetings, *D. Moore Alexander; Librarian, Nathan Raw; Editor of the Journal, R. W. MacKenna; Council, W. B. Bennet, R. E. Harcourt, A. W. Riddell, J. A. Howard, M. T. Stack, *Robert Jones, *J. Hayward Willett, *A. C. Ransome, *James Huskie, *V. Chastel De Boinville, *William McAfee, and *E. Malcolm Stockdale.

Those marked (*) did not hold the same office last year.

CENTRAL MIDWIVES BOARD.

MEETING HELD JANUARY 15TH, 1914.

SIR FRANCIS CHAMPNEYS in the Chair.

BUSINESS dealt with included a report from the Registrar General of a midwife in the Wolverhampton district who had issued two certificates—one of death and the other of still-birth—with respect to the same child. The case was referred to the Penal Committee.

A letter was read from the Medical Secretary of the British Medical Association asking the Board to reconsider its decision declining to re-appoint as a recognised teacher a medical practitioner whose period of approval had expired. The Board agreed to reply that it regretted its inability to comply with the request, and it was contrary to their practice to give reasons for their decisions. An application from the Bombay Presidency Nursing Association for recognition of their certificate as a qualification for admission to the Midwives' Roll, or, as an alternative, for leave to establish a branch examination of the Board in Bombay, was refused.

A letter had been received from the County Medical Officer for Somerset calling the attention of the Board to the difficulties which may arise in connection with the notification by a midwife of a stillbirth which has occurred before her arrival as provided by Rule E 22 (c). It was agreed that the County Medical Officer for Somerset be thanked for his letter, and that he be informed that the matter had been noted for consideration on the next revision of the Rules.

With regard to a letter from the Secretary of the Association for Promoting the Training and Supply of Midwives on the subject of the paper set at the December examination, it was agreed to reply that the Board does not discuss examination questions with correspondents.

The Resident Medical Officer of the Rochdale Union Infirmary had appealed to the Board with reference to the difficulty experienced by his pupils in obtaining outside cases for their training; but as the Board was not familiar with the local circumstances it was unable to advise on the matter.

APPOINTMENT OF EXAMINERS.

The Board passed a vote of thanks to the examiners who did not offer themselves for re-election. Those who had expressed their desire to continue were re-elected. The four London additional examiners were appointed regular examiners, and the following were appointed additional examiners:—For London: Gerald Graham Alderson, M.B., F.R.C.S., Harold Chapple, M.B., F.R.C.S., Malcolm Donaldson, M.B., William Gilliatt, M.D., F.R.C.S., Stanley Gordon Luker, M.D., F.R.C.S., Donald Whateley Roy, M.B., F.R.C.S., James Montagu Wyatt, M.B., F.R.C.S.; Bristol: Reginald Samuel Shellard Statham, M.D.; Leeds: William Gough, M.B., F.R.C.S.; Manchester: Harold Clifford, M.B., F.R.C.S., and William Fletcher Shaw, M.D.; Newcastle: William Ledingham Ruxton, M.B. St. Bartholomew's Hospital was approved as a training school.

James Alexander Fraser, M.R.C.S., L.R.C.P., and William Macdonald, M.D., were recognised as teachers.

Miss Paget reported on a complaint sent to her by the Q.V.J.I. from a certified midwife that she was inspected by an unqualified person who was not a midwife at all, but a typist who acted as clerk to the official inspector who had sent her. The Board directed that the midwife's letter be sent to the Norfolk County Council with a request for their observations thereon. Also that the attention of the inspector be called to her circular on "Migratory Midwifes," to which she had signed her name with, among others, the letters "C.M.B." after it, a practice forbidden by the Board.

DR. FREDERICK DALE, M.D., J.P., a prominent member of the Scarborough Conservative Association and one of the hon. consulting surgeons at the Scarborough Hospital and Dispensary, left estate valued at £29,521 gross, with net personalty £22,849.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Jan. 17th, 1914:

AT the Medizinische Gesellschaft, Hr. Evler showed a case that had been under his care three years before. At that time the woman had been in a very miserable condition, with her abdomen distended to more than double the size it was at present. An operation was performed, at which it was found that the case was one of

PAPILLOMATOUS CYSTOMA OF THE OVARY.

First of all ten litres of fluid were evacuated, looking like sausage soup. The growth itself, however, was so much, and so firmly adherent to the intestines and the abdominal walls that it was found impossible to remove it radically. In order to finish the operation he now stitched the cyst wall, which still contained about four litres of fluid, to the connective tissue, leaving a small opening through which the cyst could drain into the connective tissue. This was done to prevent infection and in reliance on the good effect he had seen follow autoserum treatment of tuberculous ascites. The "taking up" capacity of the connective tissue was not unlimited, however, and the same year he had to make two other punctures a few months apart, at which seven litres of fluid were let out altogether; the last time this was of yellowish-green colour. The whole of that year the opening had exercised its functions perfectly well. At the time of the last puncture he allowed the X-rays to play for a short time. After that he saw no more of the patient for two years. At the end of the second year five more litres were withdrawn by another surgeon. Now the patient had once more come under his care; she felt strong and was able to superintend her work, but she had come back on account of a gradual return of the fluid in the abdominal cavity. He estimated the quantity to be there now to be about five litres. Whether the opening was still functioning was doubtful; he would open up afresh and report again. That the tumour was a malignant one could be ascertained by feeling the parts through the abdominal wall. A tumour the size of a child's head could be felt. It was remarkable that autoserotherapy should have been carried out in such an extensive manner, and that the body should take care of such a large amount of albuminous fluid as had been admitted into it in the case.

Later.—When the new puncture was made only four litres of fluid could be obtained. The opening into the fascia was still present, but from within it was naturally closed by the pressure of the tumour. As the new opening was being made it was found that the inner surface of the cyst was studded with small, and large, easily bleeding papillomatous growths. Two years ago when the fluid had been drawn off three large tumours were to be felt, so that the one now felt to be about the size of a child's head was distinctly smaller than the one felt then; it must, therefore, have become on the whole reduced in size.

At the Verein für Innere Merizin und Kinderheilkunde, Hr. Abderhalden, Halle, read a paper on

SEROLOGICAL DIAGNOSIS OF ORGANIC CHANGES.

He first gave a short review of the knowledge of serum diagnosis of these subjects. Digestion in the stomach and intestines caused the manifold articles of food to take on their specific structure, and to simplify them so that they could form absorbable combinations. Thus the individual cells of ths body, which substances could be introduced through the mouth, always acquired the same relatively simple combinations as the nutrient material. Blood plasma had no ferments that were capable of decomposing food material. Thus the plasma of the dog did not reduce cane sugar normally, but if cane sugar was injected subcutaneously into the dog the plasma acquired the power of doing so. In a similar manner the defensive ferments against the various albuminous bodies could be pro-

duced. The method of proof of the presence of such ferments was by polarisation and dialysis, which the speaker shortly sketched. These facts led to a consideration as to whether the organism did not produce such ferments when certain tissues or cells became diseased and the products of their decomposition got into the circulation that did not do so under normal conditions. First of all it was demonstrated that such defensive ferments against pathological products were present in the case of pregnancy. It was known through Schmorl and Veit that occasionally bits of chorion cells were cast off and that they got into the blood channels. The speaker had now ascertained by the methods named that defensive material against placenta was to be found in the system from the eighth day of pregnancy up to fourteen days after the end of it. In cases of carcinoma, salpingitis, and other infections no defensive ferments against placenta were to be found. The serological diagnosis was positive, however, in carcinoma.

Examinations were now made as to whether in various other diseases pathological germs set free into the circulation were not to be rendered harmless by their own particular defensive ferments. Ferments against these diseased cells were demonstrated. In a case of Basedow's disease defensive ferments against thyroid, thymus and ovary were found. In a case of otitis media defensive ferments against the brain were met with, and the case turned out to be one of cerebral abscess. In a case of supposed carcinoma of the œsophagus no ferment against carcinoma was met with, and the case proved to be sarcoma. The defensive ferments were therefore specific. This method of diagnosis had been made use of for infective diseases, not altogether uselessly. Sometimes, but not always, the ferment against tubercle bacilli was determined.

AUSTRIA.

Vienna, Jan. 17th, 1914.

BROMISM: CUTANEOUS AND NEURAL.

AT the recent meeting of the K.k. Gesellschaft der Aertzte in Vienna, Dr. A. Goldreich exhibited a youth who had become affected with bromoderma tuberosum after internal medication with sedrobol. In discussing the history of the case, he pointed out that, according to Januschke, the genesis of chronic bromine intoxication apparently depended on displacement of chlorine from its compounds and substitution of bromine. Dr. H. Januschke then pointed out that his researches on the symptoms and causation of bromism had hitherto been directed exclusively towards elucidation of the alterations produced in the nervous system and its functions: ataxia, mental lassitude, etc. These may be warded off by administering, simultaneously with the bromine medication, corresponding atomic equivalents of chlorine in the form of common salt. Whether the substitution process would also account for the genesis of the morbid cutaneous phenomena, or whether these could be warded off in the same way—by continuous adjustment of the chlorine balance—the data which he had up to the present collected did not enable him to say. When a diet poor in its proportion of common salt was administered to the patient, an accumulation of bromine in the organism readily took place, which was the immediate cause of the genesis of the phenomena of bromism. This could be removed from the body only by the internal administration of large quantities of common salt.

PAROXYSMAL HÆMOGLOBINURIA.

Dr. Ed. Nobel exhibited a girl who suffered from paroxysmal hæmoglobinuria. The affection was ushered in some months previously by coldness and cyanotic appearance of the hands; a dark-reddish urine then appeared, and the attack soon passed off. But corresponding attacks frequently reappeared after display of the apparent effects of cold; some also were accompanied by pains in the limbs and swellings of the joints. These painful symptoms were relieved by a warm foot-bath or other local warm applications. The patient's serum was strongly hæmolytic. The girl presented indications of the presence of hereditary lues.

ANEURYSM OF ABDOMINAL AORTA IN A GIRL OF EIGHT YEARS.

Dr. Ed. Nobel also exhibited a female child, æt. 8, who presented an aneurysm involving the abdominal aorta and common iliac artery. Some years previously she had received a violent thrust near the anterior superior spine of the ilium, the impulse of which was directed towards the abdominal cavity. To the left side of the umbilicus a loud systolic murmur could be heard, which was also audible at the back. Examination with the Röntgen rays revealed the presence of an aneurysm. After an hour's exercise in a gymnasium she had passed bloody stools during the three succeeding days.

SCINTILLATING CARDIAC ARRHYTHMIA.

Dr. V. Nadel exhibited a boy of eleven years affected with scintillating arrhythmia. He had suffered from recurrent articular rheumatism, mitral incompetency, and considerable cardiac dilatation; notwithstanding which the deficiencies of compensation which presented themselves from time to time were always found in their turn to yield to the influence of therapeutic measures—so much so that, in the normal intervals, the electro-cardiogram showed no alteration of the normal cardiac mechanism; while the pulse was also perfectly regular. In comparison with the normal curve, there was merely noticeable widening and enlargement of the auricular tooth; with considerable elongation of the interval of transition. Occasionally, and apparently in connection with copious medication, various forms of derangement of the cardiac mechanism presented themselves, in one instance in the way of an alteration of interval in the form of a half-rhythm, produced by the cumulative effects of digitalis preparations, repeated extra-systolic movements, of ventricular origin, and displaying preferably the bigeminal arrangement of a swift movement and successive auricular scintillations. The extra-systolic movements originate, in all probability, in the basilar segment of the left ventricle. As those extra-systolic contractions are ineffective they furnish a deceptive indication of a falling off by half of the rate of pulsation at the wrist. On the previous day the auricular scintillations were ushered in by the appearance of a pulsus irregularis perpetuus. The scintillating movements of the auricle have a frequency of 330 per minute; the movements of the wall of the cavity are of absolute irregularity; and, in addition, we have the extra-systolic movements. The rate of ventricular contraction is 66, exclusive of the extra-systole; with the latter it amounts to 74. This, in case of a child of eleven years, indicates doubtlessly pronounced bradycardia; also some lesion of the mechanism of transmission of the normal stimulus.

Dr. H. Januschke remarked that, in the case of boys, cardiac phenomena were more frequently elicited by the administration of digalen and diuretin. Thus we have displayed an illustration of a principle which is also effective in other departments. When we endeavour to increase the activity of an organ by stimulation it may happen that exhaustion is the result; while if a smaller dosage is employed, we may attain the desired result.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

INTERESTING STATISTICS FROM THE SCOTTISH CENSUS.

THE third and final report on the Census for Scotland taken in 1911 has just been issued, and is devoted mainly to statistical studies on various subjects, of which by far the most important is the fertility of marriage. For the first time a question was inserted into the 1911 census asking as to the duration of existing marriages, the number of children born alive, and the number surviving at the date of the census. In all 762,835 married women were enumerated, and the returns concerning 680,684 were tabulated, the balance being made up of cases rejected on account of

the woman's age at marriage, and for other reasons. In tabulating the results of this inquiry, four factors had to be considered—age of wife, age of husband (both at time of marriage), duration of marriage, and number of children born. The report gives information as to the probability of any specified number of children resulting from a marriage. Thus in 11.5 per cent. of marriages in which the woman was of child-bearing age, and continued married until the end of that period, there were no offspring. The proportion of childless marriages depends largely on the age of the wife at marriage—among women married at 18 only 2.3 per cent. are unfruitful; at 28, 9.8 per cent.; at 35, 24.7 per cent.; at 40, 57.1 per cent.; to give random instances from the table. The average number of children per marriage resulting from marriages of completed fertility is 5.49. Like the preceding, the number of children varies greatly with the age of the woman at marriage. Taking from the tables the same ages as above, we find that when the age is 18 the average number of children is 8.66; at 28, 4.56; at 35, 2.29; at 40, .86. The census figures so far as they are available "afford ample evidence of a continuous drop in the fertility of marriage. The general trend can be seen from the number of children per 100 marriages for a few selected ages. Thus for the age 21 of wife at marriage, prior to 1864 there were 818, while in 1885-89 there were only 700; for age 30 there were before 1864, 494 per 100, in 1885, 89,382, for 1895, 99,332. Intimately associated with the subject of the decreasing fertility of marriage is that of the relative fertility among different classes or social grades. It has been conjectured that fertility among the thriftless and irresponsible is greater than among the intellectual and provident, and the accuracy of the surmise is in a large measure substantiated by the census returns. Fertility is tabulated under 142 occupations of the husband, and was found to be significantly greater than the mean in 30 occupations, and significantly less in 57, while in 55 the difference had no significance. The following are samples of the occupations giving the greatest and least fertility. The averages refer to marriages in which the wives were aged from 22-26 at marriage. Great fertility: Crofters, 7.04 children; plasterers' labourers, 7.01; coal heavers, 6.61; agricultural labourers, 6.42; fishermen, 6.41; quarriers, etc., 6.38. Least fertility: Civil engineers, 4.43; chemists, 4.39; clergymen, 4.33; schoolmasters, 4.25; lawyers, 3.92; doctors, 3.91; army officers, 3.76. The twelve occupations of lower fertility are all more or less of a professional character. The returns obtained in answer to the question as to the surviving children of each marriage have been utilised to throw light on the mortality of children where the mother is a wage earner. It was found that 85.2 per cent. of the children of non-wage-earning mothers were alive and 14.8 per cent. deceased, while of the children of wage-earning mothers 76 per cent. were alive, and 24 per cent. deceased. The chance of survival through the first fifteen years of life is .85 where the mother is unoccupied, but where she is a wage-earner only .76—a difference which may be otherwise expressed by saying that in the first case the chance is 5½ to 1, in the second only 3 to 1. The mortality rate varies among the different occupations of the mother. Thus 30 per cent. of the children of mothers engaged in the cotton industry died, while among dressmakers only 15 per cent. died.

The age of the wife at marriage exercises a preponderating effect on the size of the family. A difference of three years in the age of the wife at marriage means on an average about one child less at the end of the fertile period, while it would take a difference of about forty years on the age of the husband at marriage to bring about the same result. A high correlation exists between the ages of husband and wife, which shows that there is a strong bias in men and women towards securing mates of the same age as themselves. As to the continuance of fertility in marriage, the predominating factor is the duration of the marriage. For constant ages of parents at marriage there is added on to the family one child for every three or four years. For a constant duration of marriage and a constant age of husband, it takes a difference of about 13 years in the age of the wife at marriage to reduce the size of the family by one child, and in the same way, *mutatis mutandis*, a difference of 40 years in the age of the husband to produce the same result.

As to the returns of blindness, deafness, and mental defect, which have been so often criticised as inaccurate on account of the unwillingness of the community to give proper answers, those responsible for the compilation of the statistics do not exaggerate the importance of the results. The returns, especially as regards mental infirmity, are taken merely as approximate measures of the amount of infirmity in the population. The blind number 3,317, almost equally distributed among the two sexes. Those blind from infancy number 181, a decrease of 375 since 1901. One person in every 1,435 suffered from blindness. The deaf and dumb number 2,369, a decrease of 158 on last census. The total number of persons returned as mentally afflicted was 23,650—lunatics 15,719, and imbecile 7,911. There is a decennial increase in the former category of 15 per cent.; in the latter of 19.4 per cent. Of the general population one in every 201, or 4.96 per 1,000, was mentally infirm, and in 21 counties the rate among persons born in these counties was found by certain statistical tests to be significantly different from the national rate. High rates occurred among persons born in Inverness (9.19 per 1,000), Argyll (8.75), Nairn (8.41), Ross and Cromarty (8.1), and low rates in Linlithgow (3.35), Banff (3.5), and Dumbarton (3.72). Besides the above counties with high rates are Bute, Caithness, Dumfries, Elgin, Forfar, Haddington, Nairn, Orkney, Perth, Shetland, Sutherland; those with low rates are Ayr, Lanark, Renfrew, Stirling. If one divide Scotland into a highland and a lowland portion by a line from the mouth of the Dee to the Mull of Cantyre, it will be found that all the 13 highland counties except Banff are subject to a high mental infirmity rate, while of the 20 latter only 3 have a high rate, and six have a significantly low rate. There are in all 15 counties with unduly high rates, and 7 with significantly low rates. The former—Haddington, Dumfries, and Forfar excepted—are all highland; the latter—Banff excepted—are all lowland.

MEDICAL TREATMENT AND THE GLASGOW SCHOOL BOARD.

GLASGOW School Board has had before it the scheme of medical treatment for the ensuing year. Dr. Grant Andrew, in moving the approval of the minutes of the Committee on the Medical Inspection of Scholars, explained that the Scotch Education Department had laid it down that medical treatment did not cover any cases of accident or casual or serious illness, or of mentally defective children, but that it covered cases of defective vision, defective teeth, and diseases of the ear, nose and throat. The estimated expenditure was £4,758. and they hoped to obtain half of that sum from the Department if they approved of the scheme. The committee by a majority had decided not to give a grant to the Eye Infirmary as they were now undertaking the treatment themselves.

In regard to the treatment of patients suffering from tuberculosis, the Scottish Local Government Board have pointed out to Paisley Town Council that they cannot regard any scheme as complete which does not provide for taking over the treatment of cases which up till now have been dealt with by the Parish Council. Moreover, they explain the tuberculosis maintenance grant was not available to parish councils, and it was therefore in the interests of the ratepayers that treatment of poor-law cases should be afforded by the local authority. It was not essential that such cases should be treated at the local authority's hospitals. They might, in the meantime, at least, be treated at poor-law institutions at the expense and under the responsibility of the local authority, upon an arrangement with the Paris Council.

THE INSURANCE ACT AND DISPENSING FEES.

At a late meeting of the Falkirk Burgh Insurance Committee it was reported that the Scottish Insurance

Commissioners had refused to allow an extra dispensing fee to chemists for dispensing prescriptions marked "urgent" by the doctors between the hours of 9 p.m. and 8 a.m. on ordinary days and Sundays, and between 1 p.m. on Wednesdays and 8 a.m. on Thursdays, Wednesday being the shop assistants' weekly half-holiday. The clerk reported having seen a representative of the pharmaceutical committee on this matter, and the latter had written to say that the committee desired meantime to allow the matter to drop. Another communication of the Commissioners which was before the Insurance Committee was one to the effect that they were not prepared to approve, in addition to medical attendance and medicines, the supply to persons receiving domiciliary treatment of substances partaking of the nature of "maintenance"; that "treatment" was the test; and that medical comforts were only to be allowed if expressly prescribed by the medical man in attendance, not as being necessary to the patient in a general sense, but as being specific items in the treatment of the disease from which the patient was suffering. They were also not prepared to approve of expenditure on domiciliary treatment exceeding 5s. weekly. Considerable discussion took place over a case of alleged over-prescription of morphine, regarding which the local medical committee reported that while they had no reason to believe that the unusual doses of morphine prescribed by the doctor were not in the best interests of the patient, they considered that there had been prescribing of an extravagant nature. It was decided by the meeting to request the doctor to refund £5 of the cost of the prescriptions.

BELFAST.

BELFAST MEDICAL GUILD.

THE annual meeting of the Belfast Medical Guild was held in the Medical Institute on the evening of Thursday, January 15th, 1914. The reports of the Secretary and Treasurer were read and ordered to be printed and circulated amongst the members of the profession in Belfast.

The election of office-bearers for the year resulted as follows:—President, Mr. A. Fullerton; Treasurer, Dr. M. F. Cahill (Dr. Simpson, who held this office, refusing re-election); Secretary, Dr. D. Gray; Auditors, Dr. J. O'Doherty and Dr. J. Macdonald. The Secretary was re-elected as the Guild's representative on the Irish Medical Committee.

It was resolved to form a medical club in connection with the Guild, membership of the club to be open to non-members as well as members of the Medical Guild. The idea was enthusiastically received, and the Club promises to become an established success. It is hoped that the club-room will be a rendezvous not alone for the medical men in the city but also for those practitioners in the country districts who, when in town, may have an hour or two to spend before train time. A small committee was appointed to make all necessary arrangements.

The subscription to the Belfast Medical Guild was fixed at 2s. 6d. for the present year.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE QUESTION OF REFORM OF THE B.M.A.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—"An Obscure Practitioner" agrees to differ from me with regard to the *Journal*. His literary pursuits follow exactly the same line as mine, even to the reading of the local "rag." Hence we have arrived at one point of agreement. Your correspondent throws a little sidelight on the reason for his attitude towards the *Journal*, which is partly on account of the expense of production, partly because he has not time to read it. The pages of the *Journal* average 63, which means reading on an average nine pages a day. If this course of reading a few pages of the *Journal* regularly be adopted, it is wonderful what progress can be made. I am a staunch adherent of the MEDICAL PRESS AND CIRCULAR. The articles contained therein are pre-eminently practical and of great value to the busy medical practitioner. We are agreed upon this point. Personally, I have no objection to the formation of a trades union. Another point of agreement. I should like to see an organisation ensuring the combined action of the vast mass of members. It is the members of the Association alone who were to blame for the "rout" of the profession over the Insurance Act. There is too much selfishness abroad. Will such an action benefit *me* as an individual member of the profession? is the question which rules the action of so many members. We are so narrow-minded that we endeavour to safeguard the interests of the ego, and do this even if we sacrifice the interests of the profession as a whole. The Association can and will safeguard our interests if we will do our part and safeguard the interests of the Association. It is useless for an army to have guns if not supplied with ammunition; so also it is useless for the Association to have the energy, power, and desire to fight our battles if we fail to supply the necessary ammunition—financial support. If "An Obscure Practitioner" can suggest any plan by which the vast number of members of the Association will be roused from their apathy and take an active interest in matters which affect them vitally, then he may rest assured that he will have my sympathetic and practical support.

I am, Sir, yours truly,
S. J. ROSS.

Bedford.
January 15th, 1914.

A REMINISCENCE OF DR. WEIR MITCHELL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your editorial reference to the deceased on the 7th inst. recalls to mind that many years ago, when I was privileged to edit the MEDICAL PRESS AND CIRCULAR, by some mischance I was led to announce the death of Dr. Weir Mitchell, and to make comment thereupon in suitably eulogistic terms. In due course I was favoured with a note from the "deceased," in which he mildly protested against the "base insinuation." He wrote: "I cannot help thinking you are in error in announcing my death. My health may not be all that I could wish, but please take it from me that I am still alive, though I cannot but feel flattered by the remarks with which you ushered me out of the world."

This reminds me that, being in the United States in 1887 at the International Medical Congress at Washington, a cablegram was published announcing the death of Sir Richard Quain, and I was applied to by several editors to write an obituary notice of the defunct. As I was on very good terms with Sir Richard—the only one I knew of that name—I gladly complied with their request and compiled a really eloquent memoir setting forth his character and achievements in a very favourable light. Some weeks later, on my first excursion into the Harley Street district after my return to London, whom should I meet but "my" Sir Richard (the physician), whose appearance gave me quite a turn. He noticed it and laughed consumedly, exclaiming, "I shouldn't be at all surprised to find that I was indebted to you for my premature death and burial." I, of course, apologised, and expressed the pleasure I experienced to find that my eloquence had been thrown away. He added that it was almost as bad as having a statue raised to one *ante mortem*, which he hoped would never be his lot.

I am, Sir, yours truly,
ALFRED S. GUBB, M.D.

Mustapha Superieur, Algiers.
January, 1914.

THE Eddisbury Liberal Association on Saturday last adopted Dr. C. W. Hayward, of Liverpool, as prospective candidate. The Hon. Sir A. L. Stanley, Governor-Designate of Victoria, who formerly represented the constituency, attended the meeting.

OBITUARY.

DR. A. S. NEWINGTON, OF TICEHURST.

WE regret to record the death of Dr. A. S. Newington, who was killed by the overturning of his motor car at Ticehurst, near Tunbridge Wells, on Saturday afternoon last. He was driving his two-seater car from his residence, Woodlands, towards the village, when a brewers' motor dray came on to the main road from a lane, and in an endeavour to avoid a collision Dr. Newington put on his brakes, with the result that the car skidded on the slippery road. The doctor was thrown heavily, and was carried into a cottage, where he died shortly afterwards. The deceased was a well-known alienist. He was born at Ticehurst in 1845, the son and grandson of specialists in lunacy. In early manhood he spent five years in India as a planter. Returning to England, he entered at Caius College, Cambridge. He represented his university at rifle-shooting, and was well known at the Wimbledon meetings of the National Rifle Association. After graduating he proceeded to St. Thomas's Hospital whence he qualified as M.R.C.S., L.R.C.P., in 1874; the following year he graduated M.B.Cantab.

Dr. Newington practised in Oxfordshire for a few years, but about 30 years ago he became associated with the well-known private asylum at Ticehurst founded by his grandfather, of which at the time of his death he was joint proprietor with his cousin, Dr. H. F. H. Newington. He married, and is survived by, Gertrude, eldest daughter of Dr. Robert Barnes, the famous obstetrician. He leaves no family.

REVIEWS OF BOOKS.

DIET IN SKIN DISEASES. (*a*)

No dermatologist or practising physician can afford to neglect the influence of metabolic changes occurring in the body upon the nutrition of the cutaneous tissues themselves. The statement is often made that "He is the best dermatologist who is the best physician," and yet there is a great danger of concentrating too much attention upon local manifestations and remedies, and failing to appreciate the significance of the action of other systems of the body, especially the gastro-intestinal, upon the skin. From his ripe experience as a teacher and clinician, Dr. Bulkley has succeeded in cramming this helpful little work with important practical observations respecting the influence of food, beverages, stimulants, bathing and clothing upon various diseases of the skin. The chapter on the misuse of milk in many cutaneous affections and the correct manner of taking milk should be widely read. The limitation of the protein-content of a dietary has had good effect in psoriasis, more than two hundred cases of which have been treated by the author by means of a vegetarian diet with the best results. A restricted diet of rice, bread, butter and water, has been found most useful by the author in cases of acute eczema, and full directions are given for the preparation of such a diet. There are some useful food and diet tables in the appendix, as well as a comprehensive bibliography and index. In short, we consider Dr. Bulkley's book as pre-eminently one to be read by all practitioners, specialists and senior students who are interested in skin diseases.

BOURNE'S SYNOPSIS OF MIDWIFERY. (*b*)

IN a book of this kind there is little or no room for originality in the subject matter. In fact the author tells us in his preface that it is intended as a supplement to, and not as a substitute for, the ordinary text-books on midwifery. It is based on Dr. Eden's well-known text-book. In style the book resembles very closely Mr. Hey Groves's similar "Synopsis of Surgery." It presents a clear, full and concise summary of present English teaching. Where so many facts are marshalled together it is impossible that minor errors should be wanting, and a careful study of its pages has revealed very few of these. Treatment is outlined very fully, so that the book, though primarily intended to be used by candidates preparing for examination, should prove equally valuable to the qualified practitioner, who in these busy times is often in need of condensed and practical information such as is so well supplied within the covers of this book.

(*a*) "Diet and Hygiene in Diseases of the Skin." By L. Duncan Bulkley, A.M., M.D., Physician to the New York Skin and Cancer Hospital; Consulting Physician to the New York Hospital, etc. Pp. xiv., 194. London: Baillière, Tindall and Cox. 1913. Price 6s. net.

(*b*) "Synopsis of Midwifery." By Aleck W. Bourne, B.A., M.B., B.C.Camb., F.R.C.S.Eng., late Obstetric Surgeon to Outpatients, British Lying-in Hospital, etc. Bristol: John Wright and Sons, Ltd. 1913.

TRANSACTIONS OF THE OPHTHALMOLOGICAL SOCIETY. (*a*)

THE present volume comprises the proceedings of the Ophthalmological Society of the United Kingdom during its thirty-third session. The opening papers deal with vascular and other retinal changes associated with general disease, Dr. James Taylor discussing the subject from the physician's point of view, Dr. Louis Werner stating the case as it appeals to the ophthalmologist, while Mr. George Coats writes on the pathological aspects of retinal vascular disease. Mr. Arnold Lawson places on record an interesting case of glaucoma simplex treated for thirteen years without operation. The patient has been kept continuously under the influence of miotics during that time, but the dose of eserine has been gradually diminished. Mr. N. Bishop Harman has an important paper entitled "An analysis of three hundred cases of high myopia in children with a scheme for the grading of fundus changes in myopia." The paper is based on cases collected during educational work in London. The author adversely criticises the present nomenclature for changes about the disc; he proposes that the fundus should be spoken of as first, second or third degrees according as the atrophy of the disc does not exceed one-half the diameter of the disc, the whole diameter of the disc, or is greater than the diameter of the disc. The volume is well illustrated and there are several excellent plates. Though the volume will appeal chiefly to ophthalmologists, there are several papers of value to those not specifically engaged in ophthalmic work.

TRACHOMA. (*b*)

IN certain parts of this country, notably at or near large seaports, many cases of trachoma are still met with, but in most other districts the disease is conspicuous by its absence. This is not so elsewhere, and in Egypt the disease is very widespread, although of late years much has been done by prophylaxis and treatment to diminish its prevalence. In this volume the author gives a simple description of trachoma as it is met with in the East, and of its treatment as carried out at the Egyptian Ophthalmic Hospitals. He is particularly well qualified to write on the subject, as he has been able to draw on clinical material at eight ophthalmic hospitals over which he is director.

The volume is divided into four parts. In Part I., after giving a brief historical *résumé* of our knowledge of trachoma he discusses the prevalence of the disease in Egypt and the variations due to climatic and racial conditions. The stages of trachoma from a clinical point of view are described at some length. The author's classification is extremely good and is one of the best we have seen. The concluding part of this section deals with acute conjunctivitis complicating trachoma, the various types of acute inflammation being examined according to the causative micro-organism. Part II. is devoted to the consideration of pathology, there being two sections which deal respectively with morbid anatomy and the active agent. Part III. is on treatment. In the opinion of

(*a*) "Transactions of the Ophthalmological Society of the United Kingdom." Vol. xxxiii. Session 1913. London: J. and A. Churchill. Price 12s. 6d. net.

(*b*) "Trachoma and its Complications in Egypt." By A. F. MacCallan M.D.Camb., F.R.C.S.Eng., Director of Ophthalmic Hospitals, Egypt. Cambridge: At the University Press. 1913. Price 7s. 6d. net.

the author, surgical treatment is necessary to effect a cure except in very mild cases. For the treatment of early cases he gives premier place to nitrate of silver (2 per cent. solution) and he has found that the use of organic silver preparations is merely palliative. A full description is given of various operations for the radical cure of trachoma and also of operative measures for the treatment of sequelæ. In Part IV. differential diagnosis, prognosis, and prophylaxis are among the subjects discussed.

We consider that the author has made a valuable contribution to the literature on trachoma and his book deserves to be studied by all who have such cases to treat. It is to be regretted that he has not found it possible to make use of jequiritol, because with such ample material at his disposal there would have been a splendid opportunity for testing the value of this remedy which, in the hands of some ophthalmologists, has proved of service in this disease.

RESEARCHES ON RHEUMATISM. (*a*)

THIS substantial volume, devoted entirely to the results of researches into the nature of rheumatism, shows that the obscurity which still involves its ætiology is not due to lack of interest in the subject. The authors, indeed, may claim to have lifted a corner of the veil—nay, more, should the pathological status of their diplococcus be confirmed, their researches will prove fully as epoch-marking as Schaudinn's discovery of the pale treponeme, rheumatism being, after all, a much commoner and more disabling disease than syphilis. It is impossible to do justice to the immense expenditure of time and energy required for their prolonged laboratory research and clinical observation. There are valuable and exhaustive papers on acute dilatation of the heart in the rheumatism and chorea of childhood, the pathology of the myocardium, the histology of the rheumatic nodule, etc., but the interest of the work centres in the discovery of a diplococcus which the authors have shown to be present in all the tissues in typical, that is to say, infantile rheumatism. This diplococcus has been demonstrated in the vegetations of endocarditis, in the myocardium, in the nervous system, and even in the rheumatic nodule. It has been cultivated *in vitro*, and its injection in animals has determined characteristic arthritis. This brings us to another point of great interest, viz., that injections of this diplococcus in the young rabbit may give rise not only to arthritis and endocarditis, but also to appendicitis, either together or as individual lesions. This opens up a new field for conjecture in the pathology of the latter lesion.

The evidence of the constant association of the diplococcus with acute articular rheumatism is very strong, but even so it is not claimed that this organism is so specific in its cultural and laboratory tests that, obtaining a micrococcus morphologically similar from a lesion of unknown origin, it would be possible to assert its rheumatic origin.

The great difficulty arises from the fact that multiple arthritis, clinically indistinguishable from acute rheumatism, may be produced by other micro-organisms, but acute rheumatism is not necessarily manifested by arthritis, or at any rate by arthritis alone. Just as the presence of sugar in the urine does not constitute diabetes, so multiple arthritis does not necessarily spell rheumatism. Then, too, it is conceivable that there may be several different forms of acute rheumatism, just as there are different forms of pneumococcia and typhoid fever—clinically analogous but not bacterially identical. Just as laboratory research has enabled us to distinguish between typhoid and para-typhoid, and to recognise various modalities of streptococcal infection, so further research in this department may demonstrate the variability, within certain limits, of the rheumatic infection.

Assuming the diplococcus in question to be the causal agent in acute rheumatism, we are still far from the discovery of a cure; on the contrary, remark the authors, the specific treatment turns out to be an even more difficult problem than it was on commencing the investigation. The microbial agent has obtained a firm hold of the tissues before the patient comes under treatment. Then, too, owing to the extreme difficulty of differentiating the member of the streptococcal group and the difficulty experienced in preserving the virulence of the diplococcus *in vitro*, the exhaustive study of its toxins is quite impossible.

What little is known of the poison produced by the diplococcus points to the production of deleterious acids, so that alkalies may conceivably be useful in the treatment. One important point elucidated in the course of their researches is the non-specificity of the action of the salicyl group. That they reduce the fever and relieve the suffering no one will deny, but that these drugs exert any direct influence on the rheumatic lesions—arthritis, endocarditis or rheumatic nodules—the authors emphatically deny. This, of of course, does not militate against their usefulness, though it disproves their curative value.

If the view that acute rheumatism is an infective disease be substantiated, the problem of sanitation and housing will acquire special importance. It is a little discouraging to be told, after these elaborate researches, that rheumatism "has only reached the threshold of inquiry," but the elusiveness of the problems should not discourage observers from carrying on the investigation to a satisfactory conclusion. Meanwhile, our gratitude is due to the authors for this monument of industry.

The volume is copiously illustrated with several coloured plates and upwards of a hundred photogravures, most of them of great excellence. It marks a turning-point in the history of rheumatism, and in future it will not be possible to discuss the subject without reference thereto.

(*a*) "Researches on Rheumatism." By F. J. Poynton, M.D. Lond., F.R.C.P., and Alexander Paine, M.D., D.P.H.Lond. London: J. and A. Churchill. 1913.

ELEMENTS OF WATER BACTERIOLOGY. (*a*)

WE can heartily recommend this book. The authors have done much research work on the bacteria found in water, and are exceptionally well informed on their subject. An astonishing mass of information is presented to the reader in an honest and compact form. An unanimity of opinion prevails that the estimation of *Bacillus coli* is of much greater importance than any other single determination in the sanitary analysis of water. By the use of selective media, such as McConkey's lactose bile-salt broth, its absence (if such is the case) from specific amounts, is readily determined. Other organisms, however, as well as the colon bacillus produce acid and gas in this medium, and the positive results are sometimes referred to as "presumptive *B. coli*." It has long been English practice to "work up" the organisms giving this reaction to see whether they are typical *B. coli*, atypical forms of the organism, or some different bacillus. This identification is regarded by us as a point of moment and the finding naturally influences our opinion. Now two authors, whose opinions all English bacteriologists respect, proclaim "that the lactose bile fermentation test is a sufficient identification of the colon group for ordinary sanitary purposes." In spite of the statement that from 70 to 90 per cent. of the bacteria giving the "presumptive" test prove to be typical *B. coli*, we think the recommendation is retrograde.

There is a very useful chapter on the examination of shellfish, in which the advantage of examining the shell water apart or in place of the macerated fish is emphasised—a point recognised by the American Public Health Association. The authors regard Houston's standards for sewage effluents as too lenient, but *festina lente* is an English characteristic, and especially likely to appear when standards of a scientific nature are concerned. The group of organisms

(*a*) "Elements of Water Bacteriology, with Special Reference to Sanitary Water Analysis." By Samuel C. Prescott, Assistant Professor of Industrial Microbiology in the Massachusetts Institute, and Charles E. A. Winslow, Associate Professor of Biology, College of the City of New York. Third Edition. Pp. 318, xiv. New York: John Wiley and Sons, Inc. London: Chapman and Hall, Ltd. 1913. Price 7s. 6d. net.

now called *B. Welchii*, but sometimes known as *B. enteritidis sporogenes* (a name originally applied to one member of the group by Klein) is not now often used as a "bacterial indicator of pollution" in water, but when it is desired to determine it, it is safer and easier to use the native water tubed into an equal volume of milk, as suggested by Hewlett, rather than worry with a porcelain bacterial filter. Finally a chemical analysis of a water that is entirely free from ammonia and nitrates is such a rarity that its use in the manner shown on page 224 is unfair.

THE GASTRO-INTESTINAL TRACT.(a)

Dr. Wegele's book comprises, in brief systematic arrangement, many important facts which are scattered in specialised works too exhaustive for the busy practitioner. It forms an excellent reference manual in short to the diagnosis, and more especially to the treatment of the various diseases of stomach and intestines. We note that some of the more recent work, on diverticulitis, for example, is not included.

Stress is laid upon the dietetic, physical and hygienic treatment of gastro-intestinal diseases. In order to make the work more complete the editors have made extensive additions to the German work; thus, they indicate various points of diagnostic interest in connection with each disease, they have added a chapter on œsophageal diagnosis and another on the X-ray diagnosis of diseases of the stomach and intestines, etc.

The subject matter and arrangement of the book, so far as it goes, is good. Would that we could say as much of the translation. This latter is written in German-American with such an entire absence of style as to be likely to render it unpalatable to the majority of British readers.

LITERARY NOTES.

MESSRS. LONGMANS, GREEN AND CO. have in the press a work entitled "Flying: Some Practical Experiences," by Mr. Gustav Hamel and Mr. Charles C. Turner. The work will deal mainly with the practical side of aviation and will contain records of numerous personal adventures. Mr. J. Elrick Adler, F.R.C.S., will contribute a chapter on the Physiological and Medical Aspects of Aviation, and the Hon. Guglielmo Marconi one on Wireless Telegraphy. There will also be other special contributions.

* * *

THE December number of the *Indian Medical Record* is devoted to the consideration of tuberculosis and its treatment, many valuable papers being contributed upon the uses of tuberculin. Dr. T. N. Kelynack deals with the subject from the Imperial standpoint, and pleads for the elaboration in India of a scientific and systematic anti-tuberculosis campaign. Other articles by professors and practitioners in Bombay, Madras, and Calcutta, go to make up a complete symposium of the present-day position of tuberculin-therapy in tuberculosis, which will be found most useful tor reference.

* * *

THE copiously illustrated volume on "The Mechanical Treatment of Abdominal Hernia," by Dr. William Burton De Garmo, of New York (J. B. Lippincott, price 6s.), does not call for extended notice, since it is written for the information and guidance of the "hundreds of men who are doing truss fitting who are not medical men, who are doing the best work they can without either a medical education or a guide of any kind." As we hold truss prescribing to be essentially a medical function, it is not without a feeling of surprise that we see a medical man endeavouring to assist laymen in usurping medical functions. Why should a book ostensibly addressed to truss-fitters have been sent to us for review at all?

(a) "Therapeutics of the Gastro-intestinal Traot." By Dr. Carl Wegele; adapted and edited, with additions, by Maurice H. Gross, M.D., and J. W. Held, M.D. Pp. 329, with indices. London: Rebman, Ltd. 1913.

DR. CH. A. LAUFFER'S little book on "Resuscitation" (Messrs. Chapman and Hall, London) is a popular description of what he terms the "prone" method of artificial respiration. This is none other than Schäfer's method, though for some inscrutable reason the author carefully abstains from rendering unto Cæsar the credit due to him. The author's colloquial style is explained by the fact that the booklet is the reprint of a first-aid lecture delivered to men at the Pennsylvania Electrical Association. Very properly he insists upon the importance of everybody knowing how to apply the method, since, to be effectual, it requires to be applied instantly and perseveringly. There can be no question as to the superiority of Schäfer's method, because it can be applied by one man unaided, and is not as fatiguing as other methods. The illustrations, anatomical and methodical, facilitate the understanding of the text.

* * *

"Studies on the Influence of Thermal Environment on the Circulation of the Body Heat," by Dr. Edgar R. Lyth (Bale, Son, and Danielsson, Ltd.) gives the result of an elaborate series of researches, extending over ten years, on the reactions provoked by "hot" and "cold" states. These results may be summed up in the statement that in a given thermal environment a certain corresponding equilibrium of the circulatory apparatus ultimately becomes established—of which we never doubted. The acceleration of the heart-beat arising, not from relaxed arteries, but from reflex stimulation of the heart by heat, does not appear to have any positive relation to the generation or the discharge of heat. It is probably a toning up of the circulatory mechanism in view of a possible thermal emergency. We cannot help thinking that result falls short of that deserved by such long and patient investigation, but it may have bearings that escape us.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

ARNOLD, EDWARD (London).

Ulcer of the Stomach. By Chas. Bolton, M.D., F.R.C.P.Lond. Pp. 396. Price 15s.

BAILLIERE, TINDALL AND COX (London).

The Sensory and Motor Disorders of the Heart: Their Nature and Treatment. By Alex Morison, M.D., F.R.C.P.Lond. Illustrated. Pp. 270. Price 7s. 6d.

The Pocket Anatomy. Seventh edition, revised and edited by C. H. Fagge, M.B., M.S.Lond., F.R.C.S. Pp. 308. Price 3s. 6d.

CHAPMAN AND HALL, LTD. (London).

Outlines of Theoretical Chemistry. By F. H. Getman, Ph.D. Pp. 468. Price 15s.

Quantitive Analysis by Electrolysis. By Alex Classen. Translated by W. T. Hall. Illustrated. Pp. 308. Price 10s. 6d.

CHURCHILL, J. AND A. (London).

Year-book of Pharmacy, with Transactions of the British Pharmacological Conference, 1913. Pp. 706.

The Ideals and Organisation of a Medical Society. By J. B. Hurry, M.D. Pp. 52. Price 2s.

FROWDE, HY. AND HODDER AND STOUGHTON (London).

The Anatomist's Notebook. By A. M. Paterson, M.D.Edin., F.R.C.S. Pp. 350. Price 6s.

Defective Ocular Movements. By E. and M. Landolt. Translated by A. Roemmell, M.B., and E. W. Brewerton, F.R.C.S. Pp. 99. Price 6s.

Practical Prescribing with Clinical Notes. By A. H. Prichard, M.R.C.S., L.R.C.P. Pp. 308. Price 6s.

Coxa Vara: Its Pathology and Teatment. By R. C. Elmslie, M.S., F.R.C.S. Illustrated. Pp. 55. Price 2s.

GRIFFIN, CHARLES, AND CO., LTD. (London).

A Manual of Ambulance. By J. S. Riddell, M.V.O., M.D., Pp. 254. Illustrated. Price 6s.

A Handbook of Hygiene. By A. M. Davies, M.R.C.S. Fourth edition, revised by C. H. Melville, M.B., D.P.H. Pp. 718. Price 10s. 6d.

LEWIS, H. K. (London).

The Sanitary Inspector's Handbook. By Alfred Taylor. Pp. 624. Fifth edition. Price 6s.

Pocket Encyclopædia of Medicine and Surgery. By Gould and Pyle. Second edition, revised by R. J. Scott, M.A., M.D.New York. Pp. 732. Price 5s.

Lectures on Medical Electricity to Nurses. By J. D. Harris, M.D.Durh., M.R.C.S. Pp. 98. Price 2s. 6d.

LIVINGSTONE, E. AND S. (Edinburgh).

Fellowship Examination Papers of the R.C.S., Edinburgh. Price 1s.

Dental Examination Papers of the R.C.S., Edinburgh. Price 1s.

LONGMANS, GREEN AND CO. (London).

The Medical Inspection of Girls. By Catherine Chisholme, B.A., M.D. Pp. 218. Price 3s. 6d.

The Essentials of Chemical Physiology. By W. D. Halliburton, M.D., F.R.S. Eighth edition. Pp. 324. Price 5s.

Introduction to Modern Inorganic Chemistry. By J. W. Mellor, D.Sc. Pp. 684. Price 4s. 6d.

Chronic Colitis: Its Causation and Treatment. By Geo. Herschell, M.D.Lond., and A. Abrahams, M.D.Cantab. Pp. 276. Price 6s.

Controlled Natural Selection and Value Marking. By J. C. Mottram, M.B.Lond. Pp. 130. Price 3s. 6d.

NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY (London).

Proceedings of the English-Speaking Conference on Infant Mortality, August, 1913. Pp. 456. Price 3s.

The Dietetic Treatment of Diabetes. By Major B. D. Basu, Indian Medical Service. Fourth edition. Pp. 52.

PHILLADELPHIA PRESS OF W. J. DORNAN.

Medical and Surgical Reports of the Episcopal Hospital. Vol. I. Pp. 406.

PANKHURST, E. (London).

The Great Scourge and How to End It. By Christabel Pankhurst, LL.B. Pp. 155.

SAUNDERS, W. B., Co. (Philadelphia).

Principles of Surgery. By W. A. Bryan, A.M., M.D. Illustrated. Pp. 677.

Materia Medica and Pharmacology. By W. A. Bastedo, Ph.G., M.D. Illustrated. Pp. 602.

SHAW AND SONS (London).

Clinical Disorders of the Heart-Beat. By Thos. Lewis, M.D., F.R.C.P. Pp. 116. Price 5s.

SOCIETE D'EDITIONS SCIENTIFIQUE ET MEDICALES.

Thérapeutique des Cliniques de la Faculté de Paris. Sous la direction de M. Laignel-Lavaltine, Prof. Agrégé de Médecine.

Les Colites, leur Traitment Chirugicale. Par Professeurs E. Eator et E. Etienne.

UNIVERSITY OF LONDON PRESS (London).

The Principles and Practice of Medical Hydrology. By R. Fortescue Fox, M.D.Lond. Pp. 296. Price 6s.

WRIGHT, JOHN, AND SONS, LTD. (Bristol).

Natural Therapy. By T. D. Luke, M.D., and N. H. Forbes, F.R.C.S.Edin. Pp. 316, with plates. Price 5s.

Plain Rules for the Use of Tuberculin. By R. A. Bennett, M.D.Lond. Pp. 48.

Explanatory Lectures for Nurses. By H. Hawkins-Dempster. Pp. 224. Price 3s. 6d.

The Fæces of Children and Adults. By P. J. Cammidge, M.D. Lond. Pp. 516. Price 17s. 6d.

The Importance of Maritime Hospitals in the Treatment of Tuberculosis. By Dr. Jacque Cabbé. Translated by Charlotte E. Ryan. Pp. 36.

NEW PREPARATIONS.

"VAPOROLE" TINCTURE OF IODINE.

NEEDLESS to say to a medical audience, the use of tincture of iodine as a first field dressing in warfare has abundantly demonstrated its value as a powerful and comparatively non-toxic germicide. "Vaporole" Tincture of Iodine presents a pure 3 per cent. tincture, put up in handy form in a hermetically-sealed container. By breaking the point of the container the contents are allowed to saturate the surrounding absorbent material, and the product can be used as a swab. By this means fresh tincture of iodine is instantly available for sterilising the skin of operation-areas, for use upon wound surfaces of all kinds, and as a first-aid application for injuries received in workshops, factories, stables, and so on. We can recommend this preparation as one of the handiest for all practical purposes that we have met with, and one, moreover, that is adapted for all branches of private or hospital practice.

MEDICAL NEWS IN BRIEF.

The Irish Medical Committee.

A SPECIAL meeting of the Irish Medical Committee was held in the Royal College of Surgeons at 2 p.m. on Thursday, January 8th, 1914.

Owing to the absence of the Chairman and Vice-Chairman, Dr. Marlay Blake was moved to the chair.

The following members were present: Drs. J. S. Darling, S. B. Coates, E. Thompson, P. J. Hamilton, P. McKenna, J. M. Kenny, R. P. McDonnell, P. J. O'Brien, J. Keating, T. F. Higgins, F. T. P. Newell, W. A. Morton, B. C. Powell, Kathleen Lynn, E. W. Allsom, R. J. Rowlette; W. J. O'Sullivan, G. A. Hickey, J. J. O'Sullivan, T. Donnelly, L. F. Rowan, T. A. Davidson, J. C. King, D. Forde, W. F. Delany, R. C. Peacocke. Surgeon J. S. McArdle, Drs. T. Hennessy and W. W. Murphy were also present. Dr. M. R. J. Hayes, Medical Secretary, and Mr. C. H. Gick, Assistant Secretary, were also in attendance.

Apologies were received from the following: Drs. P. J. Macnamara, R. J. Johnstone, R. J. Kinkead, T. B. Costello, R. Counihan, H. S. Morrison, J. F. Fagan, H. T. Warnock, W. R. Davison, J. W. Olpherts, F. C. Fitzgerald, E. K. Frazer, J. J. Waters.

Correspondence with the Insurance Commissioners regarding the question of a truce with "Medical Advisers" not having been called, was read, and after a considerable discussion the following resolutions were passed:—

"That the Irish Medical Committee in hope of a speedy settlement of the certification question being arrived at between the Irish Insurance Commissioners and the medical profession, is of opinion that pending such settlement, or failure of the present negotiations, the existing arrangements of the Commission for obtaining evidence of sickness benefit should be acquiesced in by the medical profession, and that pending such settlement or failure of the negotiations, no professional interference should be displayed toward the "Medical Advisers."

"That in the event of a settlement of the certification question satisfactory to the Irish Medical Committee being arrived at, the Committee will use its influence to prevent any professional interference being displayed toward the "Medical Advisers."

It was pointed out that if there was to be a truce there should be a truce on the part of all contending parties, and that the Friendly Societies were still penalising those doctors who had remained loyal to the majority of their brethren, and the following resolution was passed:—

"That the Insurance Commissioners use their statutory powers and influence to prevent Friendly Societies from penalising any doctors who have remained loyal to the majority of their colleagues."

Liverpool and Tropical Diseases.

AT a Local Government Board inquiry at Liverpool last week an application was made by the City Council to borrow £194,000 for the erection of a building for the accommodation of the departments of the City Bacteriologist and the City Analyst, and of a new building for the University School of Hygiene. Mr. E. W. Pierce, Deputy Town Clerk, laid stress on the absolute necessity of making ample provision for bacteriological examinations required to safeguard the port and shipping from the importation of foreign diseases. From the latest returns it appeared that the value of Liverpool cargoes inwards and outwards exceeded £390,000,000, as compared with London's £336,000,000. Dr. Hope, Medical Officer of Health, said that unless the port was thus safeguarded Liverpool shipping would be subjected to very harassing restrictions at all the East American ports.

"Galton Day" Celebration.

ACCORDING to the *Eugenics Review*, "It has been felt for some time that steps should be taken to ensure that the name of Sir Francis Galton may be permanently connected with the eugenics movement so that, as the public becomes more and more familiar with the word, the meaning which he attached to it may not be lost sight of. For this reason the Council of the Eugenics Education Society have decided to hold annually, on February 16th, being the anniversary of his birth, a Galton lecture and dinner in commemoration of that event, hoping thereby not only to further the objects defined above but also to provide an opportunity for friendly intercourse between eugenists. The first lecture and dinner will take place on Monday, February 16th, at the Hotel Cecil. The dinner will begin at 7 p.m. and the lecture at 8.30 p.m. Sir

Francis Darwin, F.R.S., has kindly consented to deliver the lecture. The price of dinner tickets will be 7s. 6d. each. The issue of tickets, which entitle the holder to a seat at the lecture, is not restricted to members of the Society. Members and associates who do not wish to be present at the dinner may attend the lecture without payment and are invited to bring friends. Applications for tickets and all inquiries should be addressed to the Hon. Secretary, Galton Celebration Committee, Eugenics Education Society, Kingsway House, Kingsway, W.C."

The Metropolitan Hospital Saturday Fund.

LAST year was an anxious period for all interested in the work and management of the Hospital Saturday Fund (London), as the accounts for 1913, just issued, show a considerable decrease in income.

During the first three-quarters of the year there was a constant shrinkage of £100 per week in its income; but since Michaelmas the shrinkage ceased, and its income showed an advance on that for the last quarter of 1912. On December 27th the income of the fund amounted to £20,645. Between December 29th last and January 12th the sum of £9,595 was forwarded to the head office. The total receipts for 1913 were £40,272, as compared with £45,118 in 1912, £45,468 in 1911, and £42,311 in 1910.

Birth-rate, Death-rate, and Infantile Mortality during the Year 1913.

THE Registrar-General has forwarded to us for publication the provisional figures of the annual rate per 1,000 living in England and Wales, the 96 great towns (including London) and the 145 smaller towns: —Births, 23.9; deaths (standardised), 13.4; deaths under one year to 1,000 births, 109. The stardardised death-rates (formerly called corrected death-rates) are the rates which would have been recorded had the sex and age constitution of the populations of the several areas been identical with that of England and Wales as enumerated in 1901. A description of the method of standardising these death-rates is to be found in the "Registrar General's Annual Report" for 1911, page xxix.

Death under Chloroform at Shrewsbury.

THE Shrewsbury Borough Coroner (Mr. R. E. Clarke) on January 2nd inquired into the circumstances attending the death of Margaret Alice Ridgeway, aged eight years, daughter of William Ridgeway, butcher, of Wem. On the previous day, it was stated, the girl was taken to Shrewsbury to undergo an operation at a nursing home for adenoids. Dr. Whincup administered the anæsthetic to the child and Dr. Macleod performed the operation. Shortly afterwards the girl showed signs of recovering consciousness, and then suddenly died.

The jury returned a verdict of "Death from misadventure."

A Masonic Nursing Home.

THE Masonic Nursing Home Committee announce particulars of a scheme for the establishment of a nursing home, on a contributory basis, for all Freemasons who are members of lodges, whether at home or abroad, owing allegiance to the Grand Lodge of England, and, if circumstances permit, for their wives and children. The scheme aims at avoiding charity and providing an institution which will be efficient, economical and self-supporting—though there will be no attempt, of course, to make profits—and at which middle-class sufferers can obtain skilled treatment at a moderate cost. The services of the Resident Medical Officer will be included in the charges, but choice of a medical attendant or surgeon will be allowed, in which case the special fees will be a matter of arrangement for the patient.

It is proposed to erect a building in a convenient position in London equipped to accommodate 32 patients. For this the sum necessary has been estimated at £25,000, but the Committee recommend the provision of an additional £10,000 as a reserve fund to provide against all risks in the initial stages of the undertaking, so that altogether £35,000 will be required, and this sum the Freemasons of the country are asked to contribute, as, of course, no general appeal will be made.

Police Patients and Hospitals.

IT is proposed to alter the basis on which subscriptions are paid to the metropolitan hospitals from the police funds in return for the ministrations rendered to police in-patients. Hitherto certain subscriptions, says the *Lancet*, have been paid by Scotland Yard to different hospitals in a completely arbitrary way, so that it might easily happen that one charity, receiving a small subscription, would be affording treatment to 40 or 50 police in-patients during the year, while another, receiving a large subscription, might during the same year shelter only one or two policemen in the wards. Under the new arrangement the subscriptions will be approximately equal to a sum of one guinea per week on account of every police in-patient admitted to the hospital during the year.

Liebig's Extract of Meat Company, Ltd.

WE are asked to announce that the directors have resolved to declare an interim dividend of 10 per cent. free of income tax on the ordinary shares of this Company, being 10s. per share, payable on and after February 14th next to the proprietors of ordinary shares registered on the Company's books on February 5th and to holders of ordinary share warrants to bearer.

University of Liverpool.

THE following have passed the examination for the Diploma in Public Health:—H. el Arculli, G. A. Crowley, R. Gamlin, H. J. Glover, J. R. Gwynne, H. H. MacWilliams, E. S. Miller, Phœbe M. Powell, J. F. Roberts, H. Seddon, and T. W. Wadsworth.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

WORKMEN'S COMPENSATION ACT, 1906.

THE Home Secretary requests us to announce that in consequence of the resignation of Dr. Edgar Stevenson the appointment of Medical Referee under the Workmen's Compensation Act, 1906, for all ophthalmic cases arising in County Court Circuit No. 29 is now vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than the 4th February next.

DR. E. H. B.—The so-called "cure" was floated some years ago by an adventurer, with an American degree, who came to this country and spent thousands of pounds in advertising. His assertions and claims were investigated by this journal, and after exposure in our columns we were threatened with an action for libel, but the author, thinking "discretion the better part of valour," backed out.

THE WAY TO SLEEP.

SOME doctors do have funny hobbies. Says a well-known medical man: "We should sleep for at least eight hours on end." Of course, we do not know how other people sleep, but we always prefer the horizontal position.—*The Globe.*

M.B.Glasg. (London, W.).—The largest number of deaf and dumb males are employed as boot and shoe makers, the smallest as bricklayers' labourers. Among females dressmakers form the greatest proportion.

MARRIAGE PERMITTED TO ASYLUM MEDICAL OFFICERS!

THE London County Council, having found it expedient recently to increase the salaries of those engaged at the various asylums, it has now given permission to some of the assistant medical officers to get married, provided, of course, that they feel so disposed. Hitherto the rules have provided that of the assistant medical officers employed at each asylum only the first may be married. With the consent of the Secretary of State to the necessary amendment of the rules, we understand that the County Council has now arranged that the second assistant medical officers of the various institutions may also, if they desire, be married men. Very considerate of the Council!

L.S.A. (Yorks).—Although a good deal of information may be obtained by a careful examination of the lower bowel by the finger and also with the sigmoidoscope, the surest means of diagnosis would be the microscopic examination of an excised portion of the growth.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 21ST.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Presidental Address—Prof. G. S. Woodhead: The Microscope and Medicine.

THURSDAY, JANUARY 22ND.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.)—6 p.m.: Dr. M. Dockrell: Acne Vulgaris in its Three Stages—I., Comedo; II., Indurata; III., Necrotica.

FRIDAY, JANUARY 23RD.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Dr. T. R. Whipham, Dr. Eric Pritchard, Dr. J. Walter Carr, Dr. F. G. Crookshank and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF EPIDEMIOLOGY AND STATE MEDICINE AND SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Joint Meeting. Discussion on Compulsory Registration and Definition of Still Births (to be opened by a paper by Dr. R. Dudfield). (Members of the Medico-Legal Society have also been invited.)

MONDAY, JANUARY 26TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Clinical Evening. Cases will be on view from 8 p.m.

TUESDAY, JANUARY 27TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE) (1 Wimpole Street, W.).—5.30 p.m.: Discussion on Vaccines from the Standpoint of the Physician, opened by Dr. T. J. Horder, followed by Sir John McFadyean, Dr. Charlton Briscoe, Dr. Gillett (Oxford), Dr. Phineas Abraham. The Discussion will be continued on Tuesday, February 3rd, at 5 p.m., when it will be re-opened by Dr. H. D. Rolleston.

ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY (1 Wimpole Street, W.).—8.30 p.m.: Dr. D. Orr and Dr. R. G. Rows: Further Observations on the Influence of Toxins on the Central Nervous System. Dr. R. G. Rows: The Importance of Disturbance of the Personality in Mental Disorders.

Appointments.

ANDERSON, FREDK., A., M.D., B.Ch., D.P.H.Univ. Dub., Assistant Surgeon to the Eye, Ear, and Throat Hospital for Shropshire and Wales, Shrewsbury.

CARLILL, HILDRED B., M.D.Cantab., M.R.C.P.Lond., Physician to the Miller General Hospital, Greenwich.

FEARNSIDES, E. G., M.B., B.C.Cantab., Assistant Physician to the Maida Vale Hospital for Epilepsy and Paralysis.

HEPBURN, MALCOLM, M.D.Lond., F.R.C.S.Eng., Joint Lecturer in Ophthalmology at the London School of Medicine for Women.

KENNEDY, C. M., F.R.C.S.Eng., Assistant Surgeon to the Children's Hospital, Shadwell.

LLOYD, D., M.B., M.Ch.Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Denbigh District of the county of Denbigh.

SHAW, P. W., M.B., M.Ch.Edin., Certifying Surgeon for the Blairgowrie District of the county of Perth.

STEELE, J., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon for the Kidsgrove District of the county of Stafford.

WOODHEAD, Prof. G. SIMS, M.D., F.R.C.P.Edin., Consulting Pathologist to the Royal National Hospital for Consumption, Ventnor.

Vacancies.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with residence, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £180 per annum, with apartments (not board), attendance, light, and fuel. Applications to 12, Low Pavement, Nottingahm.

King Edward VII.'s Hospital, Cardiff.—Resident Surgical Officer. Salary £160 per annum, with board, laundry, and apartments. Applications to Leonard D. Rea, Secretary and General Superintendent.

Warwick County Asylum, Hatton, near Warwick.—Second Assistant Medical Officer. Salary £200, with board, lodging, and laundry. Applications to Dr. Miller, Medical Superintendent.

Swansea General and Eye Hospital.—House Physician. Salary £125 per annum, with board, apartments, and laundry. Applications to W. D. Hughes, Secretary.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Bellanaagh (Cavan), Charlestown (Mayo), Cromarty (Ross and Cromarty), Exmouth (Devon), Eye (Suffolk), Ketton (Leicester), Wellington (Somerset).

Lancashire County Asylum.—Assistant Medical Officer. Salary commencing at £250, second year £300, with board, residence, and washing. Candidates must be unmarried and under 30 years. Applications to the Medical Superintendent, Whittingham, Preston. (See advert.)

Births.

BOURNE.—On January 17th, at 9 Rutland Park Mansions, Cricklewood, N.W., the wife of A. W. Bourne, F.R.C.S., of a daughter.

CLARKE.—On January 7th, at 39 Bolingbroke Grove, Wandsworth Common, the wife of T. Alexander Clarke, M.R.C.S., M.R.C.P., of a daughter.

DEWEY.—On January 17th, the wife of E. W. Dewey, M.R.C.S., L.R.C.P., Kingswear, London Road, Portsmouth, of a daughter.

PAGE.—On January 11th, at Holly House, North Walsham, the wife of Cecil H. W. Page, M.A., M.D. Cantab., of a son.

TURNER.—On January 15th, at Westbury, Purley, Surrey, the wife of S. Duke Turner, M.D., of a daughter.

Marriages.

BAILLIE—GARGETT.—On January 1st, at St. Mary's Church, Oak Bay, Victoria, B.C., David Main Baillie, M.D., eldest son of Mrs. Baillie, of "Dunedin," Nairn, N.B., to Blanche Winifred, youngest daughter of Mr. R. B. Gargett, of Rosslyn, Palmer's Green, London, N.

COCKERELL—GILFORD.—On January 14th, at Letchworth, Herts, Douglas Cockerell, of Pixmore Farmhouse, Letchworth, to Marion Gilford, M.B., of Norton Way, Letchworth.

Deaths.

GARRETT.—On January 17th, at the Nursing Home, Huddersfield, of pneumonia, after a short illness, Gerald William Blackmann Garrett, B.A., M.R.C.S., in his 29th year, second son of F. Garrett, 6 Kent House, Kensington Court, W., late of Stanmore.

HARRIS.—On January 13th, at King's Heath, from pneumonia, Charles Herbert Harris, L.R.C.P. and S.Edin., L.F.P.S.Glasg., aged 50.

JEKEN.—On January 12th, James Jeken, of Barn House, Eltham, M.R.C.S., elder son of the late James Jeken, of Martin, near Dover, in his 88th year.

LONGTON.—On January 10th, suddenly, aged 43, George Harold Longton, M.R.C.S., L.R.C.P., youngest son of the late Edward John Longton, M.D., J.P., of the Priory, Southport, and Brown Howe, Ulverston.

NEWINGTON.—On January 17th, the result of a motor accident, Alexander Samuel Lysaght Newington, M.B., of Woodlands, Ticehurst, Sussex, aged 67.

POLITACHI.—On January 11th, at Glen Lodge, Kersal, Manchester, John Politachi, M.B., Ch.B.Edin., younger son of Constantine Politachi, Manchester.

REEVES.—On January 16th, Henry Albert Reeves, M.R.C.P., formerly Surgeon to London Hospital for Women, Royal Orthopædic Hospital for Women and Children, Shadwell, Lecturer on Anatomy at School of Medicine for Women, author of "Human Morphology and Bodily Deformities."

ROBINSON.—On January 10th, at Fleetwood, William Henry Robinson, M.R.C.S., L.R.C.P.

TURNER.—On January 16th, at Park Lodge, Buxton, Frederick Turner, J.P., Surgeon, of Merklands, Blairgowrie, Perthshire, formerly of Grafton House, Buxton, aged 70.

WISE.—On January 8th, at Lindisfarne, Trowbridge, Wiltshire, Nicholas Vincent Wise, Esq., L.R.C.S.I., L.K., and Q.C.I., L.M.I., second son of Francis George Wise, Esq., of Kilbarry House, Cork, aged 69.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, JANUARY 28, 1914. No. 4.

NOTES AND COMMENTS.

Punishment of Infirmary Patients.

THE administration of corporal punishment to an infirmary patient was the subject of a legal action tried last week before Mr. Justice Darling and a special jury in the King's Bench Division. The plaintiff was Dr. W. J. C. Keats, Medical Superintendent of the Camberwell Infirmary, who brought an action against the proprietors and printers of the *London Budget* for damages for libel in that paper, in which it was suggested that he had been guilty of cruelty in flogging convalescent boys in the infirmary. In the course of evidence it transpired that in February of last year Dr. Keats had to deal with several very refractory boys who were up to all sorts of mischievous practices, such as assaulting the nurses, putting wards in darkness by interfering with the electric light, etc. For the sake of discipline it was found necessary to chastise the offenders, and the consent and approval of the parents were obtained for so doing. The punishment—whipping with a piece of string folded five times, was administered by Dr. Keats himself in the presence of the ward sister and the nurse, and one lad "stood up and thanked him" afterwards. This mild and wholesome castigation was referred to as flogging with a five-tailed lash. A verdict was found for the plaintiff, with £100 damages, and judgment was entered accordingly. Viewing the matter impartially, it may be said that it is unwise for any medical man in an official position to assume the right of administering punishment to any patient, however refractory. Although it appears that such methods of correction are permitted by the Local Government Board, it is quite possible that the whole principle may yet form the subject of further inquiry.

Hot-water Bottles and Unconscious Patients.

ANOTHER case tried in the same court emphasises the need that exists for greater caution on the part of nurses and others who supply hot-water bottles to drowsy or unconscious patients. The plaintiff was a music student who claimed damages for personal injuries sustained as a result of the alleged negligence on the part of the servants of the defendant, a proprietor of a nursing home. Prior to being operated upon for some nasal disorder, the patient was put to bed and given a hot-water bottle by a nurse, who, after an interval of half-an-hour, returned to give him an hypodermic injection of morphia. The operation was subsequently performed successfully, but the patient awoke afterwards, feeling a severe pain in his legs, which were "covered with blisters." The jury found that there was negligence on the part of the nurse, who was acting as the servant of the defendant, and awarded the plaintiff £100 damages. The danger of leaving hot-water bottles, whether protected by coverings or not, next to the skin of unconscious or paralysed patients cannot be too strongly impressed upon nurses and attendants. Some mischief is almost sure to arise unless the practice be rigorously prohibited, for severe, and even fatal, injuries may be thoughtlessly inflicted by this means. Were it not for the extenuating fact that the patient had been the guest of the defendant for some ten weeks, the damages might conceivably have been assessed at a much higher figure.

Avoidable!

IT is no use blinking the fact that burning by hot-water bottles is an avoidable accident, a view that appears to have been adopted by the jury in the above-mentioned case. Every bottle should be wrapped in at least four or five folds of flannel or its equivalent, especially in the case of helpless, drowsy or half-conscious patients. A curious accident was recently brought to the notice of the present writer. A lady leant against an india-rubber bottle placed against her back to relieve some rheumatic pains. The bottle burst and she was rather badly scalded. On inquiry, it seems her servant was in the habit of filling the bottle with boiling water poured directly from the kettle. No india-rubber bag could stand a strain of that kind upon its seams indefinitely. The proper thing, of course, is to put a little cold water into the india-rubber bottle before adding the hot water. In all bottles, whether of rubber or earthenware, the nurse should always test the temperature, not by a momentary touch with the palm of the hand, but by the firm pressure of a naked forearm applied for one minute. If her arm cannot bear the contact for a few seconds, it is certain the patient will not bear it for a few hours. The possible inconvenience of a slight scorching may prevent a vast deal of vain regret and injury to reputation at a later stage.

The Radium Boom.

THE world-wide nature of the boom in radium has been emphasised by news from America stating that a millionaire, Mr. Henry Phipps, has offered the stupendous sum of 15,000,000 dollars for the erection and endowment of radium hospitals. Such splendid philanthropy commands our respect, even if it does not appeal to the practical common-sense of the scientific humanitarian. It eclipses in black shadow our own London Radium Institute upon which a sum of money was spent that even in England seemed con-

siderable. The weak point in the whole thing is the fact that so far radium has cured little, and that its possibilities exist chiefly in the imagination. Why spend fifteen millions on a vague romantic chance, while a fifteenth of that huge sum would equip a clinical and pathological research laboratory with the certainty of rich achievement in the conquest of disease? If the fifteen millions were spent with the definite purpose of running to earth the mysteries of measles, whooping cough, and scarlatina, with a view to their cure and prevention, a vast deal more good would accrue to humanity than by groping after the elusive potentialities of radium. Why do not millionaires take an interest in whooping cough and measles, which kill yearly a hundred times more human beings than cancer?

The Medical Superintendent of St. George's Hospital.

UNDERLYING recent events at St. George's Hospital are principles of vital importance to the medical profession. As a matter of fact, the management of that important London charity appear to have acted most unwisely in the habitual ignoring of the wishes of the Medical Committee. From later reports it seems that the Executive have recognised the folly of their ways, and have taken to heart the lesson brought home to them by the vote of the Governors of the Hospital, who plainly showed their disapproval of the proposed appointment of an honorary official to a highly salaried post. Since then two events have happened, each of them having a significance of its own. The post of Medical Superintendent of the Hospital has been advertised; and, secondly, Her Royal Highness Princess Christian has resigned the Presidency of the Institution.

A Cigarette Habit Cure.

A GROTESQUE remedy for cigarette smoking is reported from America. A New York judge, so it is stated, invited all who wished to break themselves of the cigarette habit to meet him one evening in the Court House. Three hundred men and boys assembled in response to this invitation and were met by the judge and two physicians. About fifty of them submitted to the treatment, which consisted in painting the palate with a solution of nitrate of silver. It was predicted with confidence by the physicians that for several days after the application of the drug the effect of trying to smoke a cigarette would be sickening. It is difficult to see how any remedy of the kind could do more than passing good. Meanwhile, the evil of the cigarette habit is with us on all hands. Every medical man of experience is familiar with its baneful effects upon stomach, heart and nervous system. Most of us are agreed, however, that the cure of the habit rests with the individual patient rather than with his physician. For all that, the nitrate of silver pigment may give the smoker pause for a day or two and permit his weakened will-control to resume its sway—more or less.

LEADING ARTICLES.

A STATE MEDICAL SERVICE:

ONE result of recent insurance legislation has been to direct the attention of politicians to the general question of medical service from the national point of view. Previous attempts to solve the problem have not been attended with any great measure of success. The Poor-law has failed in the first great essential of an efficient medical organisation of the kind, inasmuch as it does not secure the confidence of the class for whose relief it was created. More than that, its medical administration has been starved, thwarted, stunted and non-progressive. Not only have its medical officers been overworked and underpaid, but their professional skill has been hopelessly discounted by the dearth of such necessities as a free supply of modern drugs, surgical and medical appliances and trained nursing. The Poor-law system, it is to be hoped, will gradually fade out of existence, to be replaced by a more humane and scientifically rational Government organisation. It has proved too stubborn even for so strong a man as Mr. John Burns. Nor has the National Insurance Act relieved him of more than a small portion of his burden. The question now being discussed by social reformers is whether the panel system will have to be supplemented by a State medical service. It may be pointed out that the principle involved in a scheme of the kind is already accepted in the Poor-law medical service, as well as in Mr. Lloyd George's legislation. There is much to be said both for and against the institution of such a service. Sir John Collie recently urged it on the ground of the failure of the panel system. Surely he is jumping at conclusions in condemning a complex Act after twelve months of admittedly tentative administration. To attack the insurance system on that score is at once to drag it into the arena of party politics, which is assuredly not the right place to settle a public health question of supreme importance. On the other hand, the opponents of a national medical service will have to be prepared with stronger arguments than recently advanced by Mr. H. Kingsley Wood, a member of the London County Council. He starts off with the assumption that because a State service is of necessity salaried, it will, therefore, not draw the best and most ambitious medical men. Before his conclusions can be examined it will be necessary to learn his definition of "best" and what are his views about salaries. Surely if the salaries are large enough and a medical man is supplied with reasonably adequate resources, the State would be able to secure any requisite number of the "best" and most ambitious physicians, surgeons and specialists, especially if they were permitted to engage in private practice. The State will never attract good men with inadequate salaries. It is not the Poor-law that repels the "best and most ambitious" medical men; it is the starvation salaries paid for such work, and the impossibility of carrying it out with any satisfaction to the scientific conscience of the medical officer. No State service can be efficient nowadays without the aid of an army of operative surgeons, consultant physicians and specialists in many branches of medicine. The panel system in its

present stage fails absolutely in that direction. Much of the work that Mr. Lloyd George has thrust upon the panel doctors has been inevitably handed over to the special hospitals, or else inadequately treated. Medical men on the staffs of voluntary medical charities are in this way called upon to give gratuitous help to the furtherance of Mr. Lloyd George's great scheme of national insurance. Not only, however, are the unpaid services of hospital medical staffs exploited by the Act, but the Chancellor, under present conditions, is availing himself of the money subscribed by charitable persons for the relief of the sick poor, inasmuch as he is shifting upon the hospitals the burden of medical relief which he has undertaken to meet by the operation of the National Insurance Act—an economic situation which is grotesque and carries its own condemnation. The central feature of the State medical service appears hitherto to have escaped general attention, namely, the consent of the medical profession. Is that to be assumed as it was in the case of the Insurance Act? It is to be hoped that medical men will consider the State service at leisure before the matter is thrust upon them in the form of concrete legislation. In dealing with matters of this kind, moreover, legislators will do well to remember that consultant and practising surgeons, physicians and specialists play a distinct and absolutely indispensable part in modern medical practice.

CURRENT TOPICS.

Sixteenth century epidemics.

The epidemiological history of this country forms a most interesting chapter in the study of mediæval medicine. The condition of medical science in the days of Sir Thomas Gresham formed the principal theme of the first Gresham lecture delivered last week by Dr. F. M. Sandwith, Gresham Professor of Physic. Although the reports of the sanitary conditions prevailing in Gresham's day were contradictory there could be no doubt they were evil, the cause of ill-health, and the hotbed of those various epidemics from which the country was seldom free. There was no check upon overcrowding, windows were few and not made to open, and the water supply was very bad. Under Queen Elizabeth some attempt at sanitary reform was introduced by the Mayors and councillors. Throughout the sixteenth century plague was never absent from the Continent of Europe, and England was rarely free from it. In the first seven months of 1563 it is computed that twenty-three thousand persons died in London from plague alone. A rigorous quarantine was insisted upon, and citizens were practically kept prisoners in their own houses. Persons who were allowed to leave affected houses were compelled to carry a white rod as an indication of the fact. Queen Elizabeth adopted very strict measures for her own protection while in residence at Windsor. According to Stow a gallows was set up in the market place to hang all persons who came from London or who brought in goods from London. Small-pox was so prevalent that it came to be considered inevitable that everyone should have the disease sooner or later. Malaria, too, was rife, and ague, which would now probably be recognised as influenza, swept the country and was responsible for a high mortality. The mysterious disease known as the sweating sickness, which travelled from town to town with tragic suddenness and swiftness, was prone to attack the rich more than the poor, and the young and vigorous rather than the aged and children. After sixty-six years it disappeared, and has not been heard of since. The improvement in the public health, which has been manifest since these times, is a striking instance of the power of scientific medicine and hygiene to revolutionise the habits of the people and to rid whole nations of pestilence and devastating disease.

Co-operation in Voluntary Health Work.

A circular was issued last week, by the Local Government Board, emphasising the advantage to be derived from the co-operation in health work of voluntary workers with local authorities. A return of voluntary associations engaged primarily in health work in London has recently been brought before the Board. This return has been prepared by the Central Health Committee (Voluntary) for London, and the Board have decided to distribute copies to the Poor Law and public health authoritiess. The work of the Homeless Poor Committee is quoted as a recent example of the successful application of the principle of co-operation in London, and the Board hope that equally good results will follow from the conference on district nursing held at their office last June, at which a committee was appointed to draw up a scheme of co-ordination. The work of voluntary societies supplements that of the public authorities, but it is obvious that far too much overlapping exists. Schemes of co-operation, even of a very simple character, would be of considerable value, and the Board trust that, in those boroughs where attempts are not already being made to deal with the matter, the question will receive the earnest consideration of the Poor Law and public health authorities. The return accompanying the circular divides the societies into two groups —central and local societies. There are sixteen central societies, alphabetically arranged. They begin with the Association for Promoting the Training and Supply of Midwives and the Federation of Metropolitan District Nursing Associations (Queen Victoria's Jubilee Institute for Nurses) and end with the Women's Sanitary Inspectors' Association. The local societies comprise twenty-nine societies in twenty-one London boroughs. These societies are voluntary health societies, schools for mothers, and so on. There can be little doubt that valuable time and energy would be saved if there were greater co-operation of these excellent voluntary health-agencies.

Wisconsin Marriage a la Mode.

The up-to-the-minute legislators of the State of Wisconsin have passed a bright little law that every male applying for a licence to marry shall be examined as to the existence or non-existence of venereal disease, "so nearly as can be determined by physical examination and by the application of the recognised clinical and laboratory tests of scientific search." For this and the resultant certificate the applicant must pay a fee not exceeding $3. As a Wassermann test costs from $10-25, and as he must undertake microscopic tests for gonococci in addition to a clinical examination, not unnaturally the local Medical Society refused to work the Act. The

State has bitten off more than it can chew. The doctors were eager to work the law, and strenuously supported its principle. They can't see why they should be out of pocket over it. The present state of things is gloriously mixed. Physicians will not certify, and marriage without certification is impossible. Local report says that some couples are dispensing with the ceremony and others are skipping to another State. Anyway, the law is a dead letter; and all because of a parsimonious State. We have enough of that over here. Because our profession dispenses voluntary charity, the powers that be think we will always work for nothing. When we refuse they raise shocked hands to the skies and ask the world if such greed were ever known. It always has been so, and always will while the present type of politician endures. The great humanity that medicine teaches seems to the petty, penny mind of smart commercialism to be folly *in excelsis*. We must show that it is not.

The Literary Deluge.

WE are all more or less aware of the enormous mass of miscellaneous medical information that surrounds us. We do not realise its sinister significance. It is the sign of the times, and largely because of it we are what we are. We are all living on the brink of the volcano of the Press—its hidden forces are controlling us and moulding us, and we must beware lest we be one day overwhelmed beneath the dust of our own activity. We can point an amazed finger at the several refinements of specialism, signalling them out as typifiers of the age. But they are ultimately due not to our science, but to its works. The Brobdignagian piles of reviews, transactions, contributions and records make it impossible for a man to master more than the merest fraction of the printing press's output. This would be all very well if there were any value in this *soi-disant* "literature." The lamentable fact is that most of the stuff is very poor. Writers bolt into print at the slightest provocation. Each new case brings new problems to the painstaking physician, but that is no reason why interminable case histories should be thrust willy-nilly into the faces of our *confrères*. The fault lies largely with the journals. A rigid criticism of matter submitted would do much to check this hasty output, which is largely due to competition among men who think they cannot keep their fellows' eye in any other way. This fault of superpublication is more common in foreign countries than at home, but it affects us none the less for that—for our reading, like our profession, must be cosmopolitan, and bad habits are easily picked up. When we have indited our next monograph, let us think not whether it has a chance of publication, but whether it will be of value to the world at large.

The Folklore of London.

THAT superstition is yet rife among the masses, even of large cities, is evident to any inquirer who will take the trouble to look below the surface and penetrate into the inner life and habits of people. Medical men have abundant opportunities for studying local superstitions, especially with regard to the use of so-called "charms" against various illnesses. An interesting lecture was delivered at Horniman's Museum, Forest Hill, last week, by Mr. Edward Lovett, on "The Folklore of London," in which it was pointed out that dwellers in the metropolis were hardly less free from superstition than denizens of the country. Thus the wearing, or hanging up in buildings, of amulets appears to be far more general than one would suppose among the lower classes. That there exist to-day men making a living by selling to sailors at the East India Docks charms supposed to ensure immunity from death by drowning is not, perhaps, so very surprising, but it would be news to many that so general is the belief in the efficacy of a small quantity of mercury carried on the person in a bottle as a preventive of rheumatism that these article are actually "stocked" by one of the leading firms of wholesale chemists. In Jewish quarters one may still find exposed for sale small leaden tokens to preserve children from the "evil eye"; walking-sticks with handles resembling the clenched fist being carried for a similar purpose. Everyone, of course, knows that horse-shoes are considered to be "lucky," but it is not so generally known that the balls of silvered or coloured glass often seen hanging in the windows of small sweetstuff shops serve as "witch-balls," for the purpose of securing immunity from evil influences. Attempts to purchase these generally prove futile, perhaps for the same reason that anyone is seldom willing to dispose of a charm or to say much about its purpose. Of these luck-bringers, or safeguards against evil, perhaps the most general and the least suspected are the wooden objects often found attached to single blind-cords, which are generally in the shape of acorns, and acorns are potent against lightning. In spite of the advance of civilisation and the growth of modern medicine, it is a significant testimony to the weakness of human nature that such superstitions survive in the twentieth century.

Multiple Serositis.

THE condition known variously as polyorrhymenitis, multiple serositis, or "Concato's disease," is an interesting symptom-complex not too often seen. Essentially, the affection consists of a peculiar liability of the serous membranes of the body to consecutive inflammatory attacks. Drs. S. Solis Cohen and R. Max Goepp (*a*), of Philadelphia, have recently described a case in which the pleural and peritoneal cavities were extensively involved, in addition to adhesive pericarditis. They suggest a convenient working classification of the cases into (1) those exhibiting mainly perihepatitis, in which the peritoneum as a whole is the primary seat of the disease; and (2) those beginning with symptoms of pericarditis, and spreading later to the peritoneum. It is often impossible, clinically, to determine which organ is primarily affected. In view of the fact that chronic interstitial nephritis and arterio-sclerosis are frequently found associated with multiple serositis, it has been suggested that some toxin is at the bottom of all the trouble. The bacteriological findings have been of the most diverse description, including typhoid and tubercle bacilli, spirochætes and malarial organisms. Syphilis and tuberculosis seem to be the commonest antecedents of an interesting and obscure condition in regard to which there remains much to be learned.

The Rational Treatment of Incipient Insanity.

AT an adjourned discusssion held by the Medico-Legal Society last week, the following resolution by Dr. Robert Armstrong-Jones, and modified at a meeting of the Council, was unanimously agreed to:—"That this meeting of the Medico-Legal Society is of opinion that the early treatment of incipient insanity without certification will be advantageous, and that the Council be authorised

(*a*) *Journ. Amer. Med. Assoc.*, Jan. 3rd, 1914.

to take such steps as they may think necessary to support legislation to effect this object." It may be recalled that Dr. Armstrong-Jones read a paper upon the urgent need for legislation respecting the rational treatment of incipient insanity last November. As long as there is a certain amount of stigma attached to certification, so long will the friends of mental patients seek to avoid it, and there is a serious difficulty in determining what actually constitutes incipient insanity. The number of so-called "border-land" cases that are not certified, both acute and chronic, must be very considerable, and for the sake of these it is highly desirable that some means should be available for their prompt treatment. The system that is in operation in Glasgow, described by Dr. James Carswell, in which treatment in "observation wards" plays a prominent part, appears to be a common-sense method, and one that has yielded satisfactory results since its institution in 1904. The lunatic asylum does not commend itself as the place for the treatment of early or doubtful cases of insanity. The establishment of mental clinics in connection with the out-patient departments of the general hospitals may be advocated as likely to exert a beneficial influence in the promotion of prompt treatment for the earlier stages of mental disorder.

Hormone Therapy.

FROM the physiological standpoint, the discussion which took place last week before the Section of Therapeutics of the Royal Society of Medicine was full of interest. Since their discovery by Professor Starling in 1904, hormones have entered largely into everyday medical practice. In opening the discussion, Professor G. H. Murray classified hormones into two classes, either stimulating or inhibiting bodily processes. They are likely to be useful in the treatment of diseases due to injuries of the ductless glands, where there is a demand for increased secretion which the gland of the patient cannot meet, when the physiological action is of some use, or in some empirical way. Another classification suggested by Professor Starling is that according as to whether the chemical messengers act immediately or slowly and gradually. An example of the first class is secretin, which may be regarded as the prototype of all hormones, while thyroid extract is a good instance of the second variety. Much of the clinical experimentation of to-day is, no doubt, conducted on the lines of polyglandular therapy, and, in some cases, it must be admitted that the results obtained seem to be little short of miraculous. On the other hand, the many failures point to the fact that there is a great deal yet to be understood and many difficulties to be overcome before hormone-therapy can be said to rest upon an absolutely scientific basis.

PERSONAL.

H.M. THE KING has granted to Dr. James Ferguson Lees, Principal Medical Officer of Health for Cairo, authority to wear the decorations of the Third Class of the Imperial Ottoman Order of the Medjidieh, conferred upon him by the Khedive of Egypt, authorised by the Sultan of Turkey.

DR. J. F. HODGSON has been elected an Honorary Medical Officer of the Royal Halifax Infirmary.

AMONG the list of the new magistrates for the borough of Swansea are the names of Dr. Michael O'Sullivan and Dr. Richard Nelson Jones.

WE are informed that Mr. A. H. Tubby, F.R.C.S., Surgeon to the Westminster Hospital, has been elected a Corresponding Member of the Société Française de Chirurgie.

PROFESSOR G. ELLIOT SMITH, M.D., F.R.S., will give an open lecture at the Bedford College for Women on February 26th, the subject being "Egyptian Mummies."

SURGEON-GENERAL W. G. A. BEDFORD, C.M.G., has taken up duty as Deputy Director of Medical Services to the South African Command, in succession to Surgeon-General O. E. P. Lloyd, V.C., C.B.

DR. WILLIAM H. RIVERS, F.R.S., F.R.C.P., Fellow of St. John's College, Cambridge, who has just been made an "Officier" of the Legion of Honour of France, is well known as physiologist and anthropologist.

DR. G. DAVID WATKINS, and Mrs. Watkins, of Blackwood, Mon., were the recipients the other day of a suitable presentation on behalf of a large number of friends and admirers as a token of the esteem and respect in which they have been held in the district.

SIR RICHARD DOUGLAS POWELL, Bart., K.C.V.O., M.D., will deliver two Emeritus Lectures in the large theatre of the Middlesex Hospital Medical School, on Fridays, February 20th and 27th, at 3 p.m., on "The Therapeutic Use of Digitalis and Strychnia."

DR. PATRICK JOSEPH DUFFY, of Khedive Road, Forest Gate, has been appointed by the Pope a Knight of the Order of St. Gregory. Dr. Duffy has been for many years Surgeon to the monastery at Upton. He is also Syndic Apostolic at St. Antony's Friary, Upton.

THE Swiney Prize for Jurisprudence, founded in 1844 under the will of Dr. George Swiney, has been awarded to Mr. John W. Salmond, K.C., Solicitor-General for New Zealand, for his work "Jurisprudence." The adjudicators were the members of the Royal Society of Arts and the Fellows of the Royal College of Physicians of London.

DR. E. TURTON, of Hull, late Secretary of the East Riding and North Lincolnshire Division of the British Medical Association, was the recipient the other day of a handsome testimonial, consisting of a silver dessert service, as a mark of appreciation of his services for six years, in the last of which, in connection with the National Insurance Act, he had a most arduous time.

DR. WILLIAM MORTON ROBSON, M.D., of 73 St. Giles Street, Northampton, has been appointed by the Home Secretary to be one of the medical referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 36, and to be attached more particularly to the Ampthill, Brackley, Buckingham, Kettering, Northampton, and Wellingborough County Courts, in place of Dr. F. Buszard, deceased.

DR. C. F. HARFORD, who has been Principal of Livingstone College, Leyton, since its foundation in 1893, has intimated to the committee that he must resign his post in the summer of 1914. We understand that Dr. Harford is not retiring from active work, for he also holds the post of Secretary to the Medical Committee of the Church Missionary Society, and it is understood that he finds it impossible to carry on this work and also retain his post as Principal of Livingstone College.

FRENCH CLINICAL LECTURE

ON

PUERPERAL PHLEBITIS; ITS PROPHYLAXIS AND MEDICAL TREATMENT.

By PROF. G. KEIM, M.D.,

Ex-Interne of the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

The history of phlebitis has made some progress of late. It is indeed surprising, in view of the generalisation of antiseptic and aseptic methods, that phlebitis should still be of frequent occurrence whereas other forms of puerperal infection tend to disappear. Charrier, in his interesting work on "The Natural Defences of the Organism," called attention to this and as far back as 1900 led me to raise the question whether sepsis ought necessarily to be incriminated in all cases of puerperal phlebitis. This is a matter of the greatest importance in view of the responsibility attaching to the medical man in the event of infection taking place.

Without going into the pathogenic theories of phlebitis, I may recall two great principles, the first put forward by Cruveilhier, who insisted on the existence of an endovenous lesion since associated with a particular micro-organism; the second, long since suggested by Bouchut to explain the supervention of phlebitis in the cachectic, according to which phlebitis is not the cause, but the result, of coagulation of the blood. This coagulation is stated to be primary and dependent upon sundry mechanical and chemical causes—mechanical by slowing of the circulation, chemical by conditions governing coagulation of the blood within the vessels.

It is this second theory, hitherto not viewed with favour in France, where the tendency has been to attach only a secondary importance to the phenomena of coagulation though it appears in a certain proportion of the cases to explain the occurrence of phlebitis independently of any primary infection. This is the view I put forward in my first paper on the subject many years ago. Recent researches on the coagulation of the blood, its exact mechanism and the causes that favour or hinder its production, seem to militate in favour of the view that chemical, toxic and mechanical causes play a more important part than has been thought in the pathogenesis of phlebitis.

Among the causes that promote the formation of blood clot are liquids, especially the blood serum. Nanyn has experimentally caused thrombosis by injecting into the vessels of animals dissolved blood, weak saline solution, pure water and defibrinated blood. In the living subject these liquids only coagulate blood held up between two ligatures so that they are only operative in presence of a retarded circulation.

Conversely the intra-vascular injection of other substances in aqueous solution prevents coagulation, notably peptone and extract of leech. There is reason to believe that, in its passage through the liver, peptone yields a liquid capable of inhibiting coagulation, but however this may be, the point to be borne in mind is that peptone only acts after passing through the liver, so that it is really an exaggeration of a normal function and its production infers a healthy liver.

Now, what is the state of the liver in physiological and pathological pregnancy? As a matter of fact, the liver often undergoes more or less change, there is more or less fatty degeneration (Tanier) as shown by a slowing of nitrogenous metabolism, variations of urinary toxicity, hepatic albuminuria, glycosuria, the positive result of the alimentary glycosuria test and auto-intoxication which may culminate in eclampsia.

The less normal the pregnancy the more the liver is affected, and this is also the case in intestinal intoxication. Let us bear in mind, therefore, that the functions of the liver, especially the anti-coagulating function, may be more or less suspended during pregnancy. Then, too, we must remember that during pregnancy and the puerperium the circulation is slowed and the composition of the blood is altered. In the genital area the circulation is retarded by the elongation and dilatation of the vessels, the cardiac contraction is weakened and the circulation is impeded.

The changes which the blood undergoes also render it more readily coagulable. Physiologically this paves the way to prompt hæmostasis after delivery; pathologically it predisposes to thrombosis. Its specific gravity and alkalinity are diminished and the proportion of fibrin is increased during the last three months of pregnancy, there is an increase of the lime salts, and we know the importance of chloride of calcium in promoting coagulation; the number of leucocytes is increased and their destruction predisposes to coagulation by the setting free of thrombine.

In addition to these changes in the circulation and the composition of the blood, many causes of coagulation are present in the uterine cavity after labour, more particularly the presence of blood plasma straight from the blood, or clots which stimulate coagulation in the placental area. This action is the more pronounced the more marked the uterine inertia which allows clots to accumulate, and the freer the bleeding. The copiousness of the bleeding, especially when due to vicious insertion of the placenta, is of paramount importance in this connection.

But how does blood plasma promote the production of phlebitis? Under ordinary circumstances the uterine veins are the seat of spontaneous thrombosis after delivery, setting in during the last few weeks of pregnancy, presumably for the purpose of preventing post-partum hæmorrhage. This is true, aseptic, physiological thrombo-phlebitis limited to the internal coat of the uterus.

Let us assume that this physiological thrombosis is propagated into the deeper veins of the uterus and the peri-uterine veins and we get pathological uterine thrombo-phlebitis, which may run its course *in loco* or give rise to phlegmatia in the lower limbs.

Numerous are the causes that may lead to this extension. The placental wound, especially when situated on the lower segment, brings the blood in the sinuses into contact with the normal contents of the uterus; blood serum, clots, membranes, etc., or with the so-to-speak artificial contents of that cavity; saline or sublimated solution, the coagulating properties of which are well known.

This tends to extend the area of coagulation in the inert uterus, and so we get atonic aseptic metro-phlebitis following delivery. No sign reveals the existence of this localised uterine phlebitis, which therefore often escapes observation.

We may suspect it either when we get a rapid pulse out of proportion to the temperature or pain on one side of the womb. More frequently, however, it becomes infected, giving rise to suppurating thrombo-phlebitis with the local and constitutional symptoms of suppuration, or it may suddenly, unexpectedly, consequent upon some movement or too early rising, cause embolism, usually a large fatal pulmonary embolism.

This constitutes a first series of events which, in my opinion, explains the occurrence of phlebitis during the puerperium, apart from any infection.

Another series, fully as important, throws light on the pathogenesis of phlebitis at the end of pregnancy and the post-partum consequent upon the accidental intoxication of the organism by poisons of intestinal origin.

I have been struck by the coincidence of phlebitis and signs of intestinal toxæmia. I called attention to this in 1905 in connection with the case of a neuro-arthritic patient suffering from muco-membranous entero-colitis, who at term presented intra-abdominal venous coagulation, with pleurisy and jaundice. She suffered from phlegmatia apart from any infection.

What we should find in most cases, if we had at our disposal more exact means of investigation, would be intra-abdominal coagulation, true uterine phlebitis, in the course of pregnancy. This, though usually latent, may be revealed by pain on one side of the womb or by a pulse-rate out of proportion to the temperature. This occurs, as I have pointed out, on a soil predisposed to intra-venous coagulation, because near term the organism is demineralised, the mineral substances circulating in the blood, thus favouring coagulation. Often, too, the coagulation "breeds" on a neuro-arthritic soil, a point in common with muco-membranous enteritis.

The relationship between intravenous coagulation and intestinal intoxication is, however, much closer than this. The intestinal toxins injure the liver, and, we have pointed to the part the liver plays in promoting coagulation. We are aware, on the other hand, of the frequency with which thrombosis and embolism take place in gravidic intoxication, eclampsia, for example, and we know, too, how common intestinal fermentation is in these cases.

In the pregnant woman constipation favours the over-production of these poisons, and Jakowsky, in investigating the influence of the toxins on the coagulation of the blood, succeeded in obtaining complete artificial thrombosis with the products of the bacterium coli. It should be added that these thromboses are not peculiar to pregnancy, but are met with in other cases of intestinal intoxication; the same remark applies to phlegmatia of appendicular origin.

Before discussing the prophylaxis of these thromboses I should like to say a few words on their clinical course. Judging from personal observation, the symptoms are more fugitive and less complete than in infective phlebitis. They run a more rapid course and the prognosis as a rule is good.

A word as to their onset. Whereas infective phlebitis makes its appearance between the tenth and fifteenth day the toxic and mechanical form of phlebitis under consideration may supervene at any part of the puerperal period. We meet with it on the first or second day as well as much later between the twentieth and the twenty-fifth day.

It is easy to grasp the bearing of these remarks on the prognosis at the onset of these cases of phlebitis and the date at which the parturient leaves her bed. Apart from any infection we must familiarise ourselves with the idea that phlebitis may manifest itself late either by local signs or suddenly by embolism.

How are we to explain the disconcertingly variable onset of the phlebitis? I have often remarked that it coincides with the probable date of the missing period. At this time the organism, no longer being immunised by the fact of pregnancy against menstrual intoxication, the latter may return and intensify the toxic symptoms. This, however, is difficult to be sure of, but, in any case, the coincidence is worthy of note.

From the point of view of prophylaxis what ought the accoucheur to do? Will it suffice for him to practise antisepsis and maintain asepsis during pregnancy in order to obviate phlebitis? Certainly not; his prophylactic duty is quite different.

In the course of gestation he must treat the constipation and the enteritis, all the more so should there have been cases of phlebitis in the family, should there be the unduly rapid pulse or the lateral uterine pain, and, lastly, and especially, should the liver be already diseased—that is to say, if there be a history of jaundice or gall-stone, colic or eclampsia. I advise acting on the intestine by means of gentle laxatives, by enemata or intestinal lavages with diluted oxygenised water. We may at the same time act on the nervous system by giving hamamelis and strychnine, which exerts a tonic action on the non-striated muscle fibre of the vessels, the uterus and the intestines. The liver can be dealt with by divided doses of calomel, or by giving urotropine as advised by Richet and Renon.

Locally the prophylactic measures comprise endeavours to overcome uterine inertia and hæmorrhages, emptying the uterus of clots, membranes and blood serum, all of which make for thrombosis. Avoid introducing saline or sublimate solutions into the uterine cavity, since they exert the same coagulating action. Means should be taken to secure the prompt evacuation of the lochia, etc., and we must attend to the bowels.

It has been suggested to render the blood incoagulable, a measure which I first brought forward in 1899. This can be done by giving an enema containing an emulsion of 100 grammes of fresh calf's liver in 250 grammes of water, to which 10 grammes of pure peptone is added. My object is to provoke an anti-coagulating secretion. This seems to yield a good result in preventing thrombosis in cases where it was to be apprehended and in improving the symptoms when present.

In conclusion, the point to which I wish to call attention is that, side by side with the classical microbial infective thrombosis and phlebitis there is a form of thrombosis and phlegmasia of toxic and mechanical origin. This fact, to my mind, explains the comparative frequency of phlebitis compared with other forms of puerperal infection. The responsibility for these cases does not fall on the medical man, since they may occur in spite of anything he can do; but I would point out that uterine antisepsis may *per se* be the direct cause of the coagulation in some instances.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Charles R. Box, M.D. Lond., F.R.C.P., F.R.C.S., Physician with charge of Out-Patients at St. Thomas's Hospital, Physician to the London Fever Hospital, Subject: "Pellagra as it has appeared in Great Britain."*

ORIGINAL PAPERS.

DIRECT EXAMINATION OF THE EUSTACHIAN TUBE AND NASO-PHARYNX.

BY J. WALKER WOOD.

IN the following paper an attempt has been made to analyse the naso-pharyngeal findings in 650 cases—mostly aural. Both Eustachian tubes in each case have been examined separately by the aid of a Holmes's electric naso-pharyngoscope (Zeiss pattern), supplemented by the post-nasal mirror, the Eustachian catheter, Eustachian bougie, and the finger. As the majority of the cases have been examined on frequent successive occasions the total number of examinations is a large one.

The paper is divided into six sections :—

(1) Deformities and abnormalities of the mouth of the tube.
(2) Injuries, paralysis and foreign bodies.
(3) Inflammatory conditions. Acute and chronic.
(4) New growths: (*a*) Simple; (*b*) malignant.
(5) Adenoids.
(6) Various conditions. Varicose veins.

ABNORMALITIES IN 40.

Asymmetry of tube 3; bi-lobed posterior lip 12; supernumerary folds 3; deformed Eustachian ostium 15; bifid posterior lip 6; adventitious openings 3.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 1.—Normal Eustachian orifice. Right.
FIG. 2.—Normal Eustachian orifice. Right.
FIG. 3.—Hypertrophic salpingitis. Right. Note enlargement of posterior lip and narrowing of Rosenmüller's fossa.

Complete absence of the Eustachian tube is very rare, as is also total permanent closure; the latter is usually due to syphilis, although I have had one case under my care where total closure was most probably developmental.

Case.—H. J. E., at. 35. Deaf in right ear from childhood. Membrana tympani indrawn, fixed, adherent. Tinnitus constant, low-pitched. Deafness obstructive. Naso-pharyngoscope: Mouth of tube, lips and fossa are all much reduced in size as compared with the left one. Movements impaired. Catheter: No air can be forced into ear. Bougie arrested by hard blockage at the isthmus. No history of acquired or congenital syphilis.

Paterson (1) has recorded an interesting case of deafness due to complete occlusion of the Eustachian tubes by scar-tissue (specific).

INJURIES AND FOREIGN BODIES IN 3.

From the position of the mouth of the Eustachian tube it is obvious that direct injury must be rare. Most frequently injury takes place during the removal of adenoids and post-nasal growths. I have seen two such cases and have observed the effect of injury in one other case. Milligan (2) states that the Eustachian cushion may be amputated without any bad result.

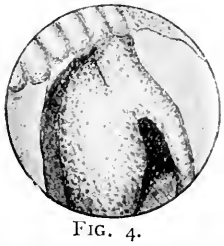

FIG. 4.

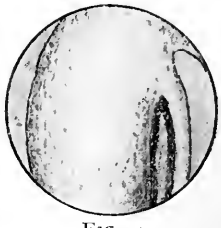

FIG. 5.

FIG. 6.

FIG. 4.—Granular salpingitis. Left. Bi-lobed posterior lip. Adenoid remains.
FIG. 5.—Extreme hypertrophy of the posterior lip. Left.
FIG. 6.—Atrophy of the posterior lip with hypertrophy of the anterior. Left.

An interesting case has been recorded by Syme (3) in which the pharyngeal portion of the Eustachian tube was torn from its position by operative procedures upon the nose, and as a sequence an adhesive inflammatory condition was set up in the middle ear with disastrous effects on the hearing, which previously had been normal.

Foreign bodies are also rare. Milligan (4) mentions a case in which a marble became wedged in the naso-pharynx and caused ulceration, sloughing, and ultimate cicatrisation of the mouth of the tube. Yearsley (5) relates a case of sudden and severe otalgia due to a gooseberry thorn in Rosenmüller's fossa.

FIG. 7.

FIG. 8.

FIG. 9.

FIG. 7.—Atrophic salpingitis. Left.
FIG. 8.—Varicose veins. Right.
FIG. 9.—Firm band in Rosenmüller's fossa, with adenoid granules in upper part of the recess. Hypertrophy of the posterior lip. Enlarged posterior and inferior turbinal with enlarged vein. Left.

INFLAMMATORY CONDITIONS IN 456.

In classifying the disorders of the Eustachian tube the inflammatory ones bulk largely in a series of unselected cases. From this investigation I have satisfied myself that a chronically inflamed Eustachian tube is never associated with normal hearing.

(1) *Simple Chronic Salpingitis*, 252.—Normally, the anterior lip is much paler in colour than the posterior, but in chronic inflammation both lips are red, the vestibule is swollen. and the triangular surface enclosed by it is reduced in size; the mouth of the tube becomes slit-like. There are often strings of mucus stretching across it. The mucous membrane may be red, dry and glazed, or soft, boggy and moist; moist usually in the early stages, dry in the later. On catheterisation air will be found to pass with difficulty. Complete Eustachian obstruction is rare (0.5 per cent. of cases). The drum-head shows either active catarrh or sclerosing changes; one rarely finds atrophy with active catarrh.

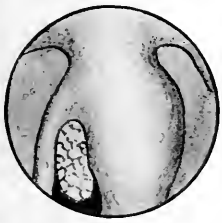

FIG. 10.

FIG. 11.

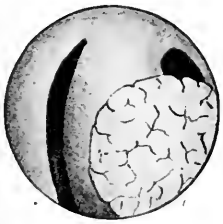

FIG. 12.

FIG. 10.—Mucous polypus in the mouth of the tube. Right.

FIG. 11.—Fibroma of cushion. Adenoid granules in Rosenmüller's fossa. Note enlarged veins. Right.

FIG. 12.—Post-nasal polypus. Left.

(2) *Hypertrophic Salpingitis*, 33.—The hypertrophy usually involves the posterior lip or the floor of the vestibule. Hypertrophy of the anterior lip is rare. In several of my cases the hypertrophy of the cushion has been so extreme as to completely block the mouth of the tube, and would have prevented catheterisation. The hypertrophy is one of sub-epithelial fibrous tissue; when felt with the probe it is found to be firm, and the application of cocaine solution has little effect upon it.

In other cases a condition more of the nature of vaso-motor rhinitis was present in which the swelling of the cushion was due to vascular turgescence, the application of cocaine being followed by a marked reduction in size. Eustachian obstruction is usually present, intermittent in character and associated with a constant low-pitched tinnitus.

Rosenmüller's fossa may be completely filled with the swollen lip and it is usual to find a retracted, catarrhal membrana tympani. The resulting deafness is only moderate in amount. Extreme forms of deafness due to chronic middle-ear catarrh are rarely found with a hypertrophied posterior lip.

(3) *Atrophic Salpingitis*, 84.—The terminal stage of chronic inflammation, and one in which we usually find atrophy and anæmia of the mucous membranes of the mouth of the tube, the tympanum, and frequently of the nose and pharynx.

FIG. 13.

FIG. 14.

FIG. 15.

FIG. 13.—Adenoid remains in Rosenmüller's fossa. Enlarged veins. Right.

FIG. 14.—Bi-lobed posterior lip. Adenoid granules in fossa. Left.

FIG. 15.—Multiple bands extending across Rosenmüller's fossa. These are probably the result of untreated adenoids. Note granules in the interstices of the bands. Left.

The mouth of the tube is patulous, the anterior lip sharp and prominent, the posterior lip reduced in size, the whole anæmic and lifeless-looking. The area of the vestibule is larger than normal. Inflation is easily carried out by Valsalva's method. Autophonia is usually present.

The tympanic membrane may be adherent, or loose and atrophic, or adherent in one part and atrophic in another. The malleus is usually fixed in all forms, and there is always marked deafness.

(4) *Granular Salpingitis*, 30.—This form precedes the hypertrophic. It is found in the early stages of middle-ear catarrh in young people and is associated with adenoids and slight deafness. The posterior lip and vestibule are usually affected. In appearance these surfaces are finely granular, moist and red, suggesting somewhat Morocco leather.

(5) *Acute Salpingitis*, 57.—This is, perhaps, the most important condition affecting the Eustachian tube, as its resulting effects are so grave. Practically all cases of middle-ear catarrh originate in catarrhal conditions affecting the naso-pharynx and the mouth of the Eustachian tube. Obstruction of the tube itself occurs later and in-drawing of the tympanic membrane or serous exudation. I have carefully inquired into many hundreds of cases of chronic middle-ear catarrh, and in a very large pro-

FIG. 16.—Post-nasal polypi. Right.

FIG. 17.—Hypertrophy of the mucous membrane of the vault and posterior pharyngeal wall. This is usually observed in long-standing cases of post-nasal catarrh. Note also the granular condition of the mouth of the tube and the enlarged vein. Left.

portion I have found that these patients suffered from attacks of ear-pain or earache in childhood. These were attacks of acute of sub-acute middle-ear catarrh and salpingitis resulting from adenoids, bad teeth or chronically inflamed tonsils.

An acute inflammation having developed, what are its symptoms?

(1) Pain, usually referred to the neck, may be radiating to the ear; almost always earache.

(2) Deafness, obstructive in character, varying with the amount of Eustachian obstruction; stuffiness in the ear.

(3) Tinnitus, low-pitched in character, humming or "popping" noises.

(4) Drum injected and red. Some drums are abnormally thin and transparent (not atrophic); in these cases the inflamed lining membrane of the middle-ear may shine through and give the appearance of an inflamed red drum, or the drum itself may be inflamed.

(5) Mouth of the Eustachian tube is red, glazed and swollen. There may be a slight mucous exudate in the mouth. The swelling is confined to the mouth and the tissues immediately around the mouth, and is not a general inflammation as in chronic salpingitis.

Movements of the mouth of the tube are often impeded. There is more or less complete Eustachian obstruction. The obstruction may be at the mouth of the tube when it is due to viscid inspissated secretion; more often the obstruction is at the isthmus. Politzerisation and inflation after the method of Valsalva fail to overcome the obstruction, and even with catheterisation air is only forced into the ear with difficulty.

The condition thus described may then follow one of three courses: (1) It may subside completely, to be followed at intervals with other attacks of varying severity. (2) It may remain in a state of subacute inflammation for some time, and it is this condition which is responsible for the formation of bands and adhesions about the mouth of the tube and in Rosenmüller's fossa. (3) It may become chronic, hypertrophic, or atrophic.

NEW GROWTHS (MALIGNANT).

Malignant disease of the mouth of the Eustachian tube is probably more common than supposed. In all cases of slight deafness, therefore, it is of the greatest importance to make a routine examination of the post-nasal space with the naso-pharyngoscope, as by its use an easy, accurate and precise examination of that region is possible. In addition, this instrument enables us to view the removal with precision of a portion of the growth, if there be one present, for microscopic examination.

The clinical picture presented by malignant disease is more or less a constant one. The signs and symptoms are:—

(1) Deafness, not usually extreme, but more characteristic of Eustachian obstruction than middle-ear disease. Membrane is usually retracted; obstruction found with catheter.

(2) Pain, typical severe trigeminal pain commencing in the third division of the fifth nerve, passing to the second, and rarely involving the first division.

(3) Abnormal condition of the palate, swelling or paresis. The immobility of the palate is said to be due to the interference with the levator palati muscle.

(4) Nasal obstruction—a much later sign, and by no means a constant one.

The constancy of the clinical picture of malignant disease in this region is readily understood when it is remembered that the Eustachian tube, the inferior division of the fifth nerve and the levator palati muscle are all found within three-quarters of an inch of each other.

SIMPLE OR BENIGN GROWTHS IN 4.

Simple or benign growths, whether of the mouth of the tube, the tube itself or its boundaries, are all of rare occurrence. Undoubtedly in the past many small growths of this hitherto "out-of-the-way" region may have been missed in post-rhinoscopic or digital examinations.

Ætiology.—Out of the 650 cases recorded here, simple benign growths were only found in four, all being women. Average age 32.

From recent records I have obtained notes of three other cases—sex, two men, one woman.

Ear Condition.—In two cases there was advanced chronic dry catarrh of the middle-ear. In one case tinnitus only was complained of with slight obstructive deafness, both cases were relieved by operation (*i.e.*, removal of growth). In one case a growth of the cushion, unattended by any ear symptoms, was found while carrying out a routine examination of the naso-pharynx.

Holmes (6) states that growths in Rosenmüller's fossa and about the cushion of the tube are common, while in the tube itself growths are rare. Out of the large number of cases examined by him a growth in the tube itself has only been found twice.

In an earlier article (7), Holmes relates one case in which he removed a polypoid growth nearly as large as an orange-seed, which was attached to the floor of the tube. It was so far within the tube that he could only see it by the aid of the naso-pharyngoscope.

CASES.

(1) *Mucous Polypus* (8).—Male, æt. 45. Deaf ten years. Right ear first, left later. No discharge. Paracusis present. Deafness obstructive. Right drum retracted. Left drum retracted and opaque. Malleus fixed. Diagnosis—chronic middle-ear catarrh. Naso-pharynx: Presenting at orifice of left Eustachian tube is seen a round, smooth, greyish-blue tumour, the size of a large cherry-stone, filling lumen of orifice and slightly bulging the lateral pharyngeal wall. Growth under observation two years, remaining stationary. Hearing varies.

(2) *Cartilaginous and Fibrous Growth* (9).—Girl, æt. 18. The site of origin was apparently the left Eustachian cushion, or the area between the latter and the upper end of the adjacent posterior pillar. It occupied the greater part of the naso-pharynx.

(3) *Mucous Polypus* (10).—N. B., motorman, æt. 56, came to me first on November 23rd, 1910, complaining of increasing deafness and crackling in the left ear for the past three weeks. Drum retracted. Deafness with forks obstructive. Post-nasal polyp size of swollen rice-granule was found to be filling the pharyngeal orifice of the left tube. It was attached to the anterior superior border of the tube, and was removed under cocaine by means of a snare introduced through the inferior meatus of this side, the wire being placed about the polypus by observing through a Hay's pharyngoscope.

(4) *Fibroma* (J.W.W.).—Miss C., æt. 35. Nasal obstruction due to hypertrophic rhinitis of inferior turbinals.—Ears normal. Naso-pharynx: Œdema of posterior edge of the septum. Enlarged posterior ends in contact with anterior lip of the tube. Large plexus of veins on anterior surface. Attached to the apex of the posterior lip (cushion) of the tube is a firm, fibrous growth, dark red in colour, distinguishing it from the rest of the Eustachian orifice. Growth not removed; diagnosis probably fibroma.

(5) *Mucous Polypus* (J.W.W.).—Mrs. B., æt. 40. Complains of popping tinnitus in right ear and intermittent deafness, slight in amount. In addition has constant low-pitched tinnitus. Drum indrawn and catarrhal. Slight obstructive deafness. Naso-pharynx: Whole

mouth of tube congested and inflamed. Lips separated by a polypoid-like growth extruding from the mouth of the tube by a narrow pedicle. The growth is like an ordinary nasal polypus in appearance and in size equal to a small orange-pip; it is freely moveable, and was easily removed by the aid of my Eustachian forceps. Pathological report states it "to have all the characteristics of a mucous polypus."

(6) *Localised Hypertrophy* (*Fibroma*) (J.W.W.).—Miss W., æt. 28 (No. 253). Chronic catarrh of the middle ear. Sclerosis of both drums. Malleus fixed. Constant tinnitus (low-pitched) several years' duration. Naso-pharynx: Attached to the anterior lip of the right Eustachian tube is a small round reddish growth. Varicose veins around it. Both lips of the tube swollen and inflamed. Growth removed with Eustachian forceps. Pathological report (Dr. Wingrave): "The growth consists mainly of white fibrous elements with patches of glands (acino-tubular) slightly degenerated. There are also some distended lymph- and blood-spaces. It may be interpreted as a localised hypertrophy of normal tissues." Following removal there was a complete cessation of the tinnitus and a marked improvement in the hearing. The lady remarked also that she had lost the "stuffy feeling" in the ear.

(7) *Fibroma* (J.W.W.).—Miss F., æt. 25. Chronic middle-ear catarrh. Drums movable, right slightly retracted. Chronic rhinitis and post-nasal catarrh. Naso-pharynx: Chronic salpingitis (moist). Both tubes. Some small varicose veins. Movements of both tubes sluggish. In the mouth of the right tube is a very small polypus-like growth not much larger than a small rice-granule. Growth removed by Eustachian forceps. The pathological report (Dr. Russ) is as follows:—"Sections from this tumour show a loose connective tissue universally infiltrated with small round cells, chiefly leucocytes, of which many are in various stages of degeneration. The histological features are those of a chronic inflammatory process." There has been a marked improvement in this patient's hearing following removal of growth.

Adenoids in 234.

(1) Adenoid masses—central and lateral, 63.
(2) Adenoid remains, 75.
(3) Adenoid granules, 96.

(1) *Adenoid Masses, Central.*—The comparative smallness of the number is accounted for by the fact that few children were examined, but practically in all an adenoid mass was found. Central adenoids are those attached to the vault of the naso-pharynx and are the commonest. Although causing nasal obstruction they rarely cause Eustachian obstruction, but by their presence may cause Eustachian inflammation and catarrh; as an influencing factor in this connection it is to be remembered that the Eustachian tube in children is shorter, more open and more horizontal than in the adult.

Lateral Masses.—It is sometimes observed that the centre of the post-nasal space is clear, while the sides of the naso-pharynx, especially in the region of Rosenmüller's fossa, are filled with masses of adenoid vegetations. They may be attached to the posterior lip of the tube and fill the mouth. Lateral masses, while not so frequent as the central, are a much more serious condition so far as the ears are concerned. Salpingitis and otitis media frequently occur, and I consider that lateral or recessal adenoids are the principal ætiological factor in producing chronic dry catarrh of the middle-ear. The frequency with which adenoid remains and granules are found in Rosenmüller's fossa in cases of old chronic middle-ear catarrh is, I think, a proof of this. It is interesting in this connection to refer to an article by F. P. Emerson in the *Annals of Otology* (11), written long before the advent of the naso-pharyngoscope. Emerson records nine cases in which adenoid remains and granules were found in Rosenmüller's fossa; seven of these cases had tinnitus and were deaf from chronic catarrh of the middle-ear.

(2) *Adenoid Remains.*—Adenoid remains are frequently seen on the vault of the naso-pharynx and in the lateral recesses (Rosenmüller's fossa). On the vault they are represented by a symmetrical wrinkling of the mucous membrane, which should not be confused with the thick, smooth, velvety, dark crimson patch usually found in post-nasal catarrhs.

In Rosenmüller's fossa adenoid remains occur more often than on the vault. Their appearance is varied. (1) The whole recess may be filled with firm, finger-like masses of adenoid tissue. (2) The adenoid masses may be in discrete, rounded, soft granular masses secreting a viscid mucus which may surround them. (3) There may be one or more strong fibrous bands extending across the upper part of the fossa from the posterior lip to the lateral pharyngeal wall. Some adenoid granules are usually seen in the recesses between the bands. I consider these bands are the remains of adenoids which have undergone fibroid change and physiological atrophy. They are to be distinguished from the more delicate bands associated with chronic inflammation of the tubal orifice and the fossa, which are usually single, much more delicate, and may extend in all directions. The association of adenoid remains with chronic catarrh of the middle ear I have already pointed out, but I may mention here that I took a hundred successive cases of chronic dry middle-ear catarrh and found either bands, adenoid remains or granules in Rosenmüller's fossa in 10 per cent. of them.

Varicose Veins in 198.

After examining a large number of Eustachian ostia one comes to recognise as being normal two small veins passing from the posterior choana over the anterior surface of the anterior lip of the tube to end in the posterior surface just at the point where the lip passes out of the field of view of the naso-pharyngoscope. Often these vessels are irregularly dilated, knotted and winding—in other words, varicose. They are then usually found associated with some abnormal condition of the posterior nares, such as turbinal hypertrophy, "mulberry" posterior ends, or polypoid degeneration. The veins of the tube communicate with those of the tympanic cavity by means of a plexus, and there are also anastomosing branches with the cavernous sinus. Any local condition, therefore, interfering with the return of blood, may cause engorgement and swelling of the Eustachian tube and ultimately of the tympanic cavity, a condition of hydrops *ex vacuo* being readily produced.

THE LIMITS OF NEPHRECTOMY IN RENAL TUBERCULOSIS.

BY DR. MICHON,
Surgeon to the Cochin Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

NEPHRECTOMY is the operation of election in renal tuberculosis, the improvements recently introduced into functional exploration of the kidney enabling it to be practised with a certainty such that no operation, save nephropexy, is as mild. Operation statistics and numerous, durable cures have gradually imposed the idea that, whenever possible, a tuberculous kidney is to be removed, and this constitutes a brilliant conquest in the domain of urinary surgery.

For some years past attempts have been made to replace nephrectomy by medical treatment, more particularly by the use of tuberculins, anti-tuberculous serums and immunising bodies. Alongside the cases of tuberculosis which do not admit of operation on account of the gravity of the infection, they now place cases in which the tuberculosis, it is believed, can be cured without nephrectomy. It is just these too mild or too severe cases of tuberculosis with which I now propose to deal.

In respect of tuberculosis of the kidney, the question arises whether comparatively recent lesions cannot be recovered from under constitutional treatment, or spontaneously, just as in tuberculosis of other organs. Little by little this opinion was abandoned, though the introduction of tuberculins and serums has led to its being re-opened. The present arguments are not anatomical. This is easy to understand, since the patients recovered; nevertheless it is surprising that in a disease as common as renal tuberculosis one so rarely meets with kidneys showing signs of healed lesions still possessing a useful parenchyma showing that this healing is possible. Nor can we take into account the exclusion of caseous kidneys with obliteration of the ureter and complete destruction of the organ after evacuation of the cavities and atrophy of the kidney as a whole. This is a mode of recovery in every way inferior to surgical ablation.

Not much is to be learned from the published cases. They are not very numerous, and few among them are trustworthy. They are of no value when, for instance, the only proof of cure is based on improvement in the general health and the subsidence of the cystitis, should the urine remain turbid and contain pus and bacilli. Improvement of health under suitable treatment is too common for it to be accepted as evidence of renal cicatrisation.

Other cases have to be excluded because the result is too recent to have any weight. We often meet with tolerably prolonged periods of quiescence in these cases, and we must not forget that tuberculosis is a disease which runs a slow course, lasting possibly for years. When pus has ceased to be present in the urine only since a short time a relapse is possible, many instances of which have come to our notice.

There remain the cases in which the urine has remained clear for a certain length of time, free from pus, and inoculation of guinea-pigs therewith has proved negative. These cases are not numerous, and are not often accompanied by information as to the cystoscopic state of the bladder and the function of the kidney before and after recovery. Is the kidney destroyed? Does it still possess useful functional capacity? Does the albumen come from the sick organ or the other?

In cases where the tuberculin treatment has been applied after nephrectomy the interpretation is less open to discussion, though one would still like to know the state of the bladder and ureter and the removed organ. Case V., published by Castaigne, is, from this point of view, full of interest. The patient, two years after left nephrectomy, again suffered with his bladder and right kidney, and his urine became cloudy and bloodstained and contained tubercle bacilli. Treatment was commenced in 1909 with I.K. and then with tuberculin. For six months the urine has remained clear, and contains no pus or albumen or tubercle bacillus. But how many cases of this kind do we see in comparison with the hundreds of cases of recovery after nephrectomy?

Now let us turn to the lessons to be draw from inspection of the anatomical specimens after removal. Some are from advanced cases of ulcero-cavernous tuberculosis; there are numerous cavities distributed throughout the renal parenchyma almost always accompanied by a sprinkling of tubercles leaving such destruction that really no interest attaches to the retention of the organ. In other specimens the excretory channels call for notice. The kidney pelvis is often dilated, the ureter is almost always thickened and indurated, and it is plain that even if healing of the tuberculous lesions takes place the kidney would become dilated and fall a prey to secondary infection. There remain the cases, unhappily too rare, in which there are only one or two small cavities limited to one horn of the kidney, or perhaps a tiny ulcer of one or more papillæ. Here, after healing, a useful kidney may be left; but in these cases the surgeon may well ask himself how to arrive at an exact diagnosis of the condition, and he cannot but be struck by the remarkable results of early intervention in such cases. Certain it is that neither the amount of pus nor the number of bacilli will help us. A small cavity, recently opened, may yield more than an extensive renal sac which has already evacuated its caseating contents. More importance attaches to functional exploration of the kidney, but here again we meet with some seriously damaged organs which still function pretty well, while nephritis plus a small tuberculous lesion may greatly diminish the permeability of the organ. Possibly by injecting collargol into the kidney pelvis under radiography might we succeed in making out the anatomical destruction and the pyelitic dilatation. It almost always happens that in early cases of renal tuberculosis we find lesions more advanced than we had expected, and rare it is for us to question the value of ablation.

This question of the extent of the lesions is one of extreme importance. It is not a matter of indifference to allow a renal tuberculosis to run on, and if improvement, instead of culminating in complete recovery, only masks destruction of the kidney, far from being an advantage it will be decidedly injurious, hindering as it does recourse to surgical measures which will only be given scope when the lower part of the genito-urinary apparatus is attacked in its turn.

The surgeon cannot overlook the good effects of early nephrectomy. At the beginning I used to treat tuberculosis by constitutional means, but had to resort to nephrectomy all the same, so much so that I have given up trying it. It comes to this, that every case of unilateral renal tuberculosis ought to be dealt with as early as possible by nephrectomy directly we detect tubercle bacilli in the urine with pus and diminished function.

On the other hand, there are advanced cases of renal tuberculosis in which nephrectomy is no longer applicable. Apart from the contra-indications based on the state of the general health, the pulmonary lesions and other visceral complications outside the urinary domain, I will discuss the indications based on lesions of the genito-urinary apparatus.

To begin with, is it invariably of advantage in unilateral cases to do nephrectomy? This question bears mostly on pyelonephritis and the comparison between nephrostomy and nephrectomy. It has lost interest during the last fifteen years. At that time it was not thought well to remove the kidney in pyonephrosis, sometimes because of precarious health but more frequently on account of the uncertainty regarding the functional integrity of the other gland. Nowadays only the first reason holds, and it does not often present itself. Nephrectomy is an excellent operation, nephrostomy is a make-shift. Then, too, the difficulty of the operation hardly counts, because, on the one hand, by sub-capsular nephrectomy, and, on the other, by evacuating the renal sac by aspiration before removing it, we are enabled to take away adherent pyonephroses of considerable size without rupture and without contaminating the field of operation.

Another question which suggests itself is whether, when a tuberculous kidney is excluded by obliteration of the ureter, it can be left without inconvenience—*i.e.*, whether this exclusion can be looked upon as equivalent to complete recovery. No such optimism is justifiable, for these kidneys are a standing menace which it would be better to do away with. When must we hold our hand in presence of a lesion of the other kidney? The lesion in question may be tuberculous or nephritic, but their bearing as a contra-indication is not the same.

In cases of bi-lateral renal tuberculosis the principle is not to operate, so that great interest attaches to the discovery of this condition. Possibly, among the cases in which after operation the tuberculosis attacks the other kidney, are some in which its existence was not recognised. Our present means of diagnosis—looking for pus, bacilli and diminution of functional activity—are not of much service, except when the tuberculous nodules are already in communication with the excretory channels. Possibly, by the complicated reaction of antigen in the urine may we succeed in arriving at an earlier exact diagnosis; but, practically, it may be stated that when we diagnose bilateral tuberculosis of the kidney the case is far advanced, and then bilateral nephrectomy is to be disadvised, even should there be a great difference in the extent of the lesions on the two sides, the trifling benefit attending removal of the most damaged kidney not compensating the gravity of the operation. To this rule there are two exceptions: a kidney which is completely destroyed functionally, especially a kidney in pyonephrosis with retention, should be removed. The pyonephrotic kidney causes pain and determines a febrile cachectic state such that removal is formally indicated, and is followed by marked improvement.

Although bilateral tuberculous lesions are rare, there is not infrequently nephritis on the healthy side. The operative contra-indication is by no means the same as in presence of tuberculosis. We must therefore seek to recognise these lesions and distinguish one from the other. Nephritis is usually manifested by slight albuminuria, 20 to 60 centigrammes, or more pronounced 1 to 4 or 5 grammes, rarely by symptoms of hydropiginous nephritis. Then too, the urine is clear, fairly coloured, does not contain pus, and inoculation is negative. In all cases where we find slight albuminuria without casts we may remove the opposite organ without hesitation, the albuminuria will remain slight or even disappear.

When the quantity of albumen is somewhat higher, say over a gramme, the problem is more difficult to solve, and before removing the kidney we must take the following circumstances into consideration: Very often, in spite of the albuminuria, the elimination of methylene blue and of sugar after injection of phloridzine is good. Often the albumin diminishes on a milk or achloride diet, in which case we may proceed with every hope of witnessing a diminution or disappearance of the albuminuria after nephrectomy. Otherwise we must hold our hand, because we must not forget that in some instances the operation has been followed by grave symptoms of nephritis in the other kidney.

It remains for us to discuss vesical and genital lesions in man. Here the problem is much more delicate. The vesical lesions, though they often dominate the scene, never constitute a contra-indication. However severe, there is everything to gain from ablation of the diseased kidney; indeed, the bladder may recover completely. None the less interest attaches to the question which cases of cystitis subside at once and which remain to complicate the good effects of nephrectomy. Cystoscopy will afford us the necessary information. In cases with not very severe lesions and those in which the lesions are serious but are situated near the ureteral orifice proving descending infection, these as a rule subside rapidly after operation. Bad, on the contrary, are the cases in which the cystitis or the ulcers are distributed all over the fundus with concomitant prostatic lesions. In both cases, however, nephrectomy should be performed; the only drawback is a less rapid and less complete recovery.

The same remark applies to tuberculosis of the epididymis and prostate. This is not a contra-indication to the operation. It is often only the consequence of the renal tuberculosis, whether the latter is latent or patent. Under these conditions ablation of the kidney can only do good. We often see the epididymitis finish by getting well, the prostatic lesions less frequently. To establish a perfectly accurate diagnosis we should require to be able to distinguish the cases in which the renal tuberculosis preceded the invasion of the genital apparatus from those in which the tuberculosis started in the latter, and this is often materially impossible. All we know is that the former is the commoner course. It is therefore our practice to remove the tuberculous kidney which has revealed its presence in spite of the existence of genital tuberculosis, seeking by the special means at our disposal to ascertain whether there is hidden renal tuberculosis, in order to remove it in cases of prostato-epididymal lesions which at first sight seemed to be primary. It must not be forgotten that genital tuberculosis increases the difficulty of exploring the kidney, prevents the cure of the cystitis, and aggravates the post-operative prognosis of nephrectomy, so that if we decide to remove the kidney in spite of the genital tuberculosis our ideal must be to do so before descending infection has taken place.

Nephrectomy is, therefore, to be had recourse to whenever practicable in cavernous tuberculosis of the kidney; but if all our patients are to be benefited thereby we must not leave untouched the cases in which the disease is only commencing or those which appear too complicated. It is imperative to establish the indications for operation after separate functional exploration of the two kidneys by double ureteral catheterism.

THE YELLOW FEVER DANGER FOR ASIA AND AUSTRALIA, ESPECIALLY AFTER THE OPENING OF THE PANAMA CANAL. (a)

BY DR. J. J. VAN LOGHEM,

Director of the Institute of Tropical Hygiene, Department of the Colonial Institute, Amsterdam, Holland.

THE possibility of yellow fever spreading further, especially after the opening of the Panama Canal, has been repeatedly pointed out; the first time, as far as I know, by Strong (1) and Manson; the latter in 1903 read an important paper on "The Relation of the Panama Canal to the Introduction of Yellow Fever into Asia," at the February meeting of the Epidemiological Society.

The question has an American and an international side. The American side does not come under discussion at this Congress; the way in which they fight yellow fever in America is a lesson to the whole world. The international side, however, is well worth treating. The Council of this Section seemed of the same opinion, and invited me to read an introductory paper. Although I cannot call myself a yellow fever authority, I accepted this invitation, being convinced that my task is merely to bring the subject up for discusson in order to give the authorities assisting at this Congress an opportunity of letting light shine on it.

As the question of the yellow fever danger for Asia and Australia, considered from the present point of view, is entirely entomological, we can restrict ourselves to a study of the distribution and biology of Stegomyia (Aedes) calopus in those continents.

STEGOMYIA ON BOARD SHIPS.

Stegomyia calopus can remain infectious very long after having bitten a yellow fever patient; so if the mosquito find on board the means of keeping alive there is danger of the disease being carried over distances. Repeated experience of the occurrence of

(a) Paper read at the Section of Tropical Medicine and Hygiene, International Congress of Medicine, London, July, 1913.

yellow fever among the crew and dock labourers during the unloading of ships (the last time in 1908 at St. Nazaire, when Chantemesse (2) caught stegomyia on board *La France*) has proved this.

In tropical seas stegomyia not only remains alive on board ship, but sometimes also finds an opportunity of breeding, as is known from many observations. Personally I have some experience about the steamers of the "Kon. Ned. Paketvaart," plying between the ports of the Dutch Indian Archipelago.

When, in July, 1909, my wife and I came on board the steamer *Reynst* at Belawan (east coast of Sumatra), which ship then plied between Soerabaya (Java) and Belawan *via* Singapore (and so remained only a few degrees north and south of the equator), we were, on entering our cabins at about noon, attacked by some dozen stegomyiæ. The breeding-places did not seem to be far away; we found, in fact, larvæ and pupæ in the water-tank of the bathroom next to our cabin, and imagines against the sides of the tank. During the voyage we held an examination with the captain, and besides in the bathrooms found larvæ in the bilge water. I ought to add here that at sea we soon got rid of the mosquitos in our cabin; it seems that they are driven from on board in great numbers by the drought, as has also been observed by Gudden (3) on board a man-of-war.

The self-cleaning of the ship during its course is certainly an important point, and the faster the ship runs and the better it is ventilated the less chance there is of its carrying yellow fever. On the other hand, it is clear that the advantages of the newer ships over the slow-going sailing ships—one of the synonyms of yellow fever was ship's fever (4)—is to a certain extent reduced by their dimensions being larger and their interiors more complicated. And then we are not to forget that the coast places in tropical seas are also connected by primitive native ships.

On account of all this I think I am right in concluding that as long as yellow fever occurs in America, the chance remains of infected stegomyiæ being transported to Asia and Australia. So we have to ask ourselves a second question: When the disease has been transported to Asia and Australia, will it maintain itself there?

THE OCCURRENCE OF STEGOMYIA IN ASIA AND AUSTRALIA.

Entomologists teach that Stegomyia calopus occurs all over the world between about Lat. 40° N. and S. We know of stegomyia being found at all possible places in Asia and Australia within those boundaries.

Information as to the occurrence of Stegomyia calopus is not sufficient for the epidemiologist. We want quantitative data about stegomyia in its relation to man, in the same way as we desire them nowadays about rats and fleas or about malaria-parasites and anopheles-mosquitoes in a scientific treatment of the epidemiology of plague or of malaria. The short time I have at my disposal for writing this paper prevents me from carefully inquiring whether from various parts of Asia and Australia such quantitative data have already been collected, as are comparable to data about stegomyia in yellow fever centres.

From the available literature I cannot gather that such investigations have been made on a large scale (5); I may express my hopes though that in a short time further particulars will be forthcoming specially from British India; it is known that a British Indian Commission is occupied with the study of the yellow fever danger for British India.

As regards the Dutch Indies, I am able to give you some data collected by myself. In the years 1908-9 my wife and I inquired into the existence of Stegomyia calopus at Medan, the capital of Deli, east coast of Sumatra. Medan is situated on the coast, and so has an equatorial sea climate; on the average a high degree of moisture even in the relatively dry periods and a very small variation of the average temperature in the course of the year (between 25° and 27° Celsius).

Our attention was drawn to the mosquito because it worried us so much: we inhabited two rooms in a sort of bungalow next to the main building of the hotel, with in front a verandah and at the back a bathroom. The other rooms in the bungalow were identical with ours; they also had a bathroom with w.c. Most of the other rooms were meant for ordinary hotel guests, and so remained often uninhabited for a shorter or longer period.

We found at the beginning of our stay that in the daytime—more especially in the hot hours before and after noon—it was simply unbearable in our verandah. The moment you sat down quietly in order to read or write you were attacked by numberless mosquitos.

We determined those mosquitoes, and they were Stegomyia calopus, which was confirmed by Professor de Meyere at Amsterdam. Having recognised the mosquito we were able to put an end to the nuisance; an inspection of the adjoining hotel rooms showed us in the reservoirs (6) of the temporary unused bathrooms small quantities of water, in some cases yellowish-grey and non-transparent because of all the larvæ and pupæ swarming in it. We found also larvæ and pupæ in the water left in the unused w.c., which had not been washed out for a few days. It was sufficient to explain the matter to the hotel-keeper; he had the reservoirs screened and took better care to have the closets in the unused rooms washed out.

On inquiring we found that we were not the only persons troubled by day mosquitoes; in most of the European houses we generally found in the bathrooms and in the outhouses (kitchen, etc.), stegomyia larvæ, once even in the little basin with water for the copying-brush on the writing-desk.

It stands to reason that we do not get a good insight into the real frequency of Stegomyia calopus on the east coast of Sumatra from the European population living in beautiful houses surrounded by neatly-kept gardens. Therefore our hotel experience is important in showing that where no proper precautions against stagnant water are taken, stegomyia uses the opportunity to multiply in an extraordinary degree.

We published our experiences in Deli at that time in *Geneesk Tijdschr. v. Ned.-Indië*, vol. xlviii, 1908, with request to send us specimens of Stegomyia calopus from other parts of the Dutch Indies. To distinguish it from St. scutellaris, which occurs frequently in the woods of Deli, we added photographs to our treatise on which the "lyre" was distinctly visible. From different places in Sumatra, Java, Borneo, and New Guinea colleagues complied with our request. The present chief of the Civil Medical Service, Dr. de Vogel, then at Semarang, wrote to tell us that after the congress in Berlin (1907) he was very much interested in the yellow fever question for Dutch India, and told us further that Marlatt had collected Stegomyia calopus at different places in Java. Connecting all these various experiences we deduced that Stegomyia calopus is of frequent occurrence, especially in places along the coast of Dutch East India, but also at a considerable height. Personally we found the mosquito as Garoet and Malang, places situated respectively 700 and 400 metres above the sea level; on the contrary, not at Bandar Baroe (900 m.) and the plateau of Toba (1,400 m.) in Sumatra, nor at Tosari (1,700 m.) in Java.

We also received information that gave us some idea as to the quantitative occurrence of Stegomyia calopus. Dr. van Dijk (Atjeh, Sumatra) wrote to us on November 17th, 1908: "Among 30 mosquitoes caught I find three stegomyia"; Dr. v. d. Zijl, on the little Dajak river in the interior of Borneo, wrote on October 12th, 1908: "The mosquito occurs here rather frequently, so much so that if you are bitten in the middle of the day, you are nearly sure of having to do with a Stegomyia fasciata."

No doubt at all as to the frequency is left by Dr. Baggelaar's letter from Fak Fak, in New Guinea, November 30th, 1908: "I hereby send you some 15 Stegomyiæ fasciatæ. It is swarming here with these wretched animals. They are only surpassed in their untiring zeal for biting by the wood mosquito. In the months of October to December they are most frequent. The specimens sent all have the 'lyre' intact, having been carefully selected from dozens of specimens."

If we compare the temperature of Dutch India with the optimal temperature for breeding experiments with

stegomyia, it is not to be wondered at that in uncivilised countries as New Guinea, or where the stagnant water is neglected, as in the hotel at Medan, stegomyia multiplies in great numbers.

	Jan.	Feb.	Mar.	Apr.	May	June
Batavia (Java)	25·4	25·4	25·8	26·2	26·4	26
Medan (Sumatra)	25·2	25·9	26·3	25·9	26·5	26·3

	July	Aug.	Sept.	Oct.	Nov.	Dec.
Batavia (Java)	25·7	26	26·3	26·5	26·2	25·7
Medan (Sumatra)	26	26·1	25·8	25·3	25·8	26

Out of mosquito eggs which I received on February 14th, 1913, from Professor Fülleborn at Hamburg, and which were placed in water at an air-temperature of 26° C. in an incubator at Amsterdam, the first imagines were hatched on February 24th.

According to Finlay (7) the optimum is only slightly higher (29°—31° C.), which tallies with the epidemiological optimum. From observations during thirteen years Finlay made up the following average (Military Hospital at Havannah) :—

	Jan.	Feb.	Mar.	Apr.	May	June
Temperature	22·2	23	23·3	23·2	26·5	28·1
Cases	137	142	195	326	658	1683
Deaths	52	43	65	140	240	528

	July	Aug.	Sept.	Oct.	Nov.	Dec.
Temperature	28·6	23·3	27·5	25·9	24·2	22·3
Cases	2493	1614	1036	586	376	189
Deaths	817	495	311	182	189	79

One sees from this that in Asia throughout the whole year the average temperature near the equator is about equal to the temperature at which yellow fever can prevail in America, and remains only little below the average temperature at which the disease becomes a serious epidemic.

If from our observations in East Dutch India, which can by no means lay claim to completeness, any conclusion may be drawn, it must be this: it may be surmised that at various places in Asia and Australia stegomyia occurs in such numbers and under such circumstances that yellow fever, once transported there, will be able to hold its own and be propagated further. But further inquiries to confirm this provisional conclusion are badly wanted.

Measures to be Taken in Asia and Australia against the Yellow Fever Danger.

I want to sum up shortly the measures to be taken against the yellow fever danger, and more especially to call attention to the conflict which will again arise between hygiene on one side and commerce and traffic on the other.

Every ship arriving in the stegomyia zone from an infected or suspected port must remain at a sufficient distance from the coast, and be examined for mosquitoes, larvæ, and yellow fever patients. If this examination has a negative result the ship shall be given free pratique. If mosquitoes and larvæ are found they are killed, and yellow fever patients are carried from the ship in mosquito-nets and nursed in a mosquito-proof hospital.

But the trouble is that stegomyia may be on board, hidden in the cargo, without any chance of their being discovered by the harbour officials; among the patients with fever—but not clinically recognisable as yellow fever—there may be yellow fever patients; and among the healthy people may happen to be some in the incubation period of the disease.

So the conclusion which might be drawn from this is; that every ship having touched at an infected or suspected harbour in the stegomyia zone ought to be fumigated; that the whole (non-immune) crew ought to be kept in quarantine and observed for a few days, and that all the fever patients ought to be taken from on board in mosquito-nets and isolated in a mosquito-proof hospital.

As compensation for the mistakes that without doubt will be made in the execution of these measures, the campaign against stegomyia in the Asian and Australian ports ought to be started with all energy. If then the ship mosquitoes really make victims on shore, the condition for spreading further is lacking.

It must be owned that if the propagation of yellow fever continues in South America, and the traffic between Asia and Australia and the yellow fever districts increases, a proper execution of the above-mentioned measures will prove to be not without objections.

In order to relieve the local sanitary services in the harbours of some of their work and responsibility, and to further the rapidity with which ships in the harbour are controlled, more things ought to be entrusted to the ships' doctors. I think that in the future a more important and more honourable task will be given them than nowadays; more especially will they be better prepared for their task.

Surely it is clear that the supervision of the rat mortality on board, of the suspected sufferers from yellow fever and cholera, of stegomyia in the cargo, and breeding-places of stegomyia on board, would be better in the ship's doctor's hands than with the harbour doctor. But it is necessary that the ship's doctor should be well versed in the bacteriological diagnostic of plague and cholera, as well as in recognising and fighting stegomyia, and that there should be an opportunity on board for him to confirm that diagnosis.

If the physiological kitchens of steamers can dish up perfect French dinners, why should not the bacteriological kitchen be able to produce an agarplate, Löffler preparation, or agglutination test.

With respect to the above-mentioned recommendations, the question naturally arises whether it would not be possible to join hands, and through international co-operation secure the safety that is not sufficiently guaranteed by the local measures in the harbours.

The idea of international co-operation has already been expressed; I shall restrict myself to a short synopsis of the ideas mentioned by Manson, Gray and Agramonte.

Manson's idea is confined to the defence of Asia by cleaning the ships on their voyage through the Panama Canal; this hygienic work ought to be internationally regulated and executed. The meeting at which this plan was suggested decided to have it studied by a Commission; I am sorry to say I am ignorant as to whether this Commission has really drawn up a report, and whether this has been published. In consequence of Manson's proposition an article appeared by Gray (8), who more especially drew attention to the fact that yellow fever is endemic not only on the Atlantic, but also on the Pacific side of America. He pointed out the irregular political state in those countries, which does not guarantee the proper execution of hygienic measures in the harbours. So Gray wants all ships sailing from a yellow fever port to an Asiatic one to be obliged to first touch at the fumigation-station at Panama. He also thinks that international control of navigation should be kept there.

At the Congress for hygiene in Berlin in 1907, the thought of international co-operation was uttered by Agramonte, who again clearly showed what danger the yellow fever centres in Ecuador, Colombia, Venezuela, etc., have for the whole tropical zone. The motion of the Cuban delegates, however, with respect to the calling together of an international conference was not discussed, as is shown by the Congress reports.

With Dr. de Vogel, chief of the civil sanitary service in Dutch India, I consider it a matter of regret that

at the present moment, when the Panama Canal is soon to be opened, and we may shortly expect a large increase of navigation between America and Asia, we have not yet been enlightened by such an international conference. The problem is really one the solution of which no doubt possesses great difficulties, which can only be examined by an international committee, and cleared away by a joint action of the Governments concerned.

Finally, I give a synopsis of the contents of this paper in the form of a few questions.

(1) Is the chance of yellow fever being transported by ships from America to the stegomyia zone of Asia and Australia of practical hygienic importance?

(2) Is this chance increased by the opening of the Panama Canal.

(3) Does Stegomyia calopus occur in regions of Asia and Australia in such numbers as to cause danger of the disease becoming endemic here and there and causing epidemics?

(4) (*a*) Are the sanitary officers in Asia and Australia to restrict themselves to local measures in the harbours? (*b*) Or should an attempt be made to arrive at international co-operation?

(5) Will the 21st Section of the 17th International Congress of Medicine in London present a motion to the Congress for appointing a commission charged with the study of plans for international action against the yellow fever danger in Asia and Australia?

OPERATING THEATRES.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

ARTHROTOMY OF HIP.—MR. EDRED M. CORNER said that he was about to operate upon a child with tuberculous disease of hip, both the head of the femur and the acetabulum being diseased. Far and away the most satisfactory method of exposing the hip joint would be demonstrated. A curved incision was made through the skin and fascia, beginning just below and behind the anterior superior spine of the ilium, crossing the great trochanter and passing upwards on to the buttock, the termination of the incision not being so high as its commencement. The flap so marked out, consisting of skin, fat and fascia, is raised. The anterior edge of the gluteus minimus is shown and the tip of the great trochanter above the level of the neck of the femur is detached. In this case, and in children where the bone is cartilaginous, the detachment of the tip of the trochanter is easily done with a knife. In older subjects it is necessary to use a saw. The tip of the trochanter with the muscles attached to it is drawn upward. In doing this it will be noticed that the hip joint and the neck of the femur are exposed. Indeed, there is no exposure of the hip joint, such as a surgeon operating in the region of that joint ought to have, which is to be compared with that given by the method of operation now demonstrated.

It will be noticed that in this case the capsule is thick and soft with disease. It is now incised, and by flexing the hip in adduction of the leg the head of the femur is easily dislocated from the acetabulum. Now it can be seen that both the head of the femur and the acetabulum are diseased. Also it will have been noticed that the ligamentum teres is destroyed. It usually is so in chronic conditions of the hip joint, such as tuberculous disease, or the slow separation of the epiphysis of the femur. The latter is a curious condition, but it would appear that the separation of the epiphysis from the neck of the femur is accompanied by the weakening and even the disappearance of the ligamentum teres in the joint. This is hard to explain, except on the hypothesis that the bony separation has robbed the ligament of its function; being functionless it wastes, even disappearing in time.

It is very noticeable how thoroughly this method of operation allows the surgeon to do what work is required in the joint. Having curetted and removed all trace of disease, the joint is closed without any drainage being employed by simply attaching the detached tip to the trochanter with a catgut stitch, and closing the skin wound with three rectangular mattress sutures and a continuous one of catgut to close the edges. The stitches in this continuous stitch are inserted close together and close to the skin edge. In this way more even and perfect closure of the wound is obtained. This point is very important, as if unsealed the wound is very easily infected during the nursing of the case.

Mr. Corner said that he would now narrate three examples of cases of tuberculous disease of the hip, in which he had done the operation in this way.

A CASE OF TUBERCULOUS HIP, PARTIAL REMOVAL OF THE DISEASE.—D. C., a boy æt. 4, was brought to the hospital in May, 1910, suffering from tuberculous disease of the right hip joint. A large abscess was present which did not respond to repeated evacuation by tapping, so that it was necessary to expose the hip by the method just advocated, and eradicate the disease both in the head of the femur and in the acetabulum. By this method all disease could be removed so that the wound was closed and remained healed ever after. This is an example whereby a "by-no-means maiming operation" with modern *technique* may in a few months secure such a result as may take at least one year's residence in a sanatorium.

TUBERCULOUS HIP IN WHICH THE DISEASE WAS TOO EXTENSIVE FOR THE IMMEDIATE SUCCESS OF THE OPERATION.—G. M., æt. 9, was admitted to the hospital with tuberculous disease of the hip and an abscess in connection with the joint. This abscess could not be cured by repeated tappings and so the hip joint was opened in the manner advocated. The disease affected the head and neck of the femur, the acetabulum and side of the pelvis. So far as could be seen all the disease was removed. The trochanter united with the femur by a catgut suture. The wound was closed without drainage, but broke open in part, leaving a discharging sinus which had not healed about three months later. The child has improved enormously in general health, and though the disease was too extensive to be removed entirely, its partial removal has helped the child so much that recovery with a stiff hip will ensue.

EXTENSIVE TUBERCULOSIS OF THE HIP: OPERATION: DEATH LATER.—E. L., æt. 3, was admitted to the hospital on November 23rd, 1912. There was an old history of tuberculous disease of the right hip for some time. On admission a large abscess was present. After repeated tapping of the abscess had been tried and failed, the cavity was incised, curetted and closed. By January 8th, 1913, the abscess had again reformed, and the child was complaining of starting pains and had an irregular temperature. The hip joint was exposed as recommended and the disease of the bone found to extend from the trochanter on to the pelvis. All disease was removed and the wound closed. About four months later the child was discharged from hospital with the wounds soundly healed. But tuberculosis was present elsewhere, the child dying some months later from general tuberculosis. All this time the hip remained healed, and this case is quoted

by Mr. Corner to illustrate the fact that even in a very bad case of hip joint disease, the patient dying of general tuberculosis, it was possible through the incision recommended to eradicate the local disease entirely so that the wound remained healed and well.

In conclusion, Mr. Corner said that operation on tuberculous disease of the hip was only justified if there was no sepsis introduced and no sinuses allowed to form. Hence the most approved method of operation and the perfection of *technique* and hæmostasis were absolutely essentials.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 9TH, 1914.

The President, R. D. PUREFOY, M.D., P.R.C.S.I., in the Chair.

(*a*) CANCER OF SIGMOID; (*b*) CANCER OF RECTUM; (*c*) SARCOMA OF ILEO-CÆCAL REGION.

MR. PRINGLE showed three examples of operation for malignant disease of the bowel. The first specimen showed an excavating ulcer on the lower end, which was found to be carcinoma of the bowel, and was removed by the combined abdominal and peritoneal method. The patient was a man, æt. 65. The second specimen was a ring stricture of the sigmoid. The case came to him as one of acute obstruction, and the bowel was resected three days later, and the patient is now doing well. The third specimen was sarcoma of the small intestine close to the ileo-cæcal valve. Radical operation was done and several feet of the ileum removed and an anastomosis made between the ileum and the transverse colon. The patient was now out of hospital and was gathering strength, but was being treated with antimeristem.

The PRESIDENT asked the age of the patient from whom the cancerous cæcum was removed, and how long the symptoms of obstruction continued before there was anything in the case to point to more than increasing constipation. He considered there was much difficulty in trying to decide in those cases as to whether there was really malignant disease.

Mr. PEARSON inquired what determined Mr. Pringle in the case of acute obstruction to do a cæcostomy, as the contents of the bowel from the cæcum were extremely irritating to the skin. He would have preferred to do a colostomy in the transverse colon.

Mr. BLAYNEY mentioned a case of acute obstruction which was at present under his charge, and said that in dealing with such cases a very distended abdomen was usually met with, and the operator had no means of determining what the position of the growth was, and he suggested that the first thing that should be done was to make an incision in the middle line. He had experienced no irritation of the skin after cæcostomy, although such might be expected.

Professor TAYLOR thought that in cases of cancer, where obstruction was present in the large bowel, the procedure mentioned by Mr. Blayney was the best, *i.e.*, to deal with the obstruction by means of a temporary opening in the cæcum. He could speak from some experience of the very beneficial effects of a cæcostomy preliminary to the major operation. He enquired as to the scope of the resection operation and pointed out that one might deal with stricture of the sigmoid with a certain amount of bowel at each side and a corresponding amount of mesenteric tissue, or it might be dealt with by a large amount of bowel and the removal of a much larger lymphatic area. He asked if Mr. Pringle made it a practice to carry out this wide extirpation of these lymphatic glands.

Mr. W. I. DE C. WHEELER mentioned that five years ago he advocated drainage of the intestine through the cæcum. and he had since no reason to regret this. He could never see any practical objection to cæcostomy.

Mr. PRINGLE, in replying to the remarks, said that the age of the patient referred to by the President was 62. He had increasing constipation for a year, and there was obstruction for over ten days. There was no question as to the diagnosis. He suggested that an aid in such cases was the administration by mouth of a bismuth meal, supplemented by bismuth given through a tube. Another method was the use of the sigmoidoscope. He had found the latter to be quite safe. Regarding cæcostomy, he would always do it when there was a chance of carrying out a radical operation. He had not found that it gave rise to irritation. He recognised the necessity for dealing with as wide a lymphatic area as possible, and thought that a cord-like stricture, such as that shown, was very likely due to malignant growth. He explained that antimeristem was of the nature of a vaccine.

(*a*) COMPLETE COLECTOMY; (*b*) SARCOMA OF THIGH; (*c*) CANCER OF STOMACH (ÆT. 27).

Mr. W. I. DE C. WHEELER said that the first specimen was a colon removed for mucous colitis. The patient was operated on twice before the colon was removed. Sections were made of the specimen, but there was nothing pathological to be found. The second specimen was taken from a patient, æt. 55, who had a lump in his thigh which was removed, and proved to be spindle-celled sarcoma. The interest of the case was what was going to happen to the patient. The third specimen was taken from a patient, æt. 27. He did not like to diagnose cancer on account of the patient's age, but found marked carcinoma on the lesser curvature of the stomach. He considered the prognosis was very bad.

Mr. BALL mentioned a case of spindle-celled sarcoma in which the patient complained of an abscess in the thigh. This was opened, and it seemed to be something into which a hæmorrhage had taken place. The pathological report was that it was a fibroma into which a hæmorrhage had taken place. Six months afterwards a small, hard lump occurred in the thigh; this was removed and found to be a spindle-celled sarcoma. It again recurred on two occasions, but the partient recovered, and was well now for over three years.

Mr. PEARSON asked had the sarcoma any attachment to the bone, and what determined Mr. Wheeler in doing a wide local removal?

The PRESIDENT, referring to the case of mucous colitis, inquired what was the prognosis as to the improvement in the general health of the patient. He remarked that these were shocking cases to have to deal with, but he thought he could recall some in which the condition disappeared. However, the intractable nature of the malady had been long recognised.

Mr. WHEELER, replying to the remarks, said that the patient had no mucous colitis now, and, as far as the bowels were concerned, they were regular. He had been treating the case for a couple of years before doing the colectomy. He had presupposed sarcoma and removed it widely. It had no attachment to the periosteum.

RADICAL OPERATION FOR CHRONIC OSTEOMYELITIS.

Mr. SETON PRINGLE read a communication on this subject. He first called attention to the unsatisfactory results obtained by the old "gutter" operation. He stated that he believed the cause of persistent sinuses after this operation was the fact that a cavity was left with hard bony walls which could not fall in and assist in obliteration of the space left. The operation he advocated consisted in the removal of the greater part of the shaft of the bone in such a way that the soft tissues were able to fall in and obliterate any cavity left. In some cases he advocated the complete sub-periosteal resection of the shaft of the bone. He gave notes on some five cases in which one or other operation had been carried out, illustrating the cases by lantern slides from X-ray photographs of the bones.

Mr. BLAYNEY said that he considered this the most important paper read at this section of the Academy for some time past, as it represented a definite step in the treatment of those cases, which, on account of the prolonged treatment necessary, were very troublesome. He mentioned that since he had first heard of the procedure he had been carrying out the operation with very satisfactory results. He agreed that granulation tissue had a very limited growth, and it, therefore, took a very long time for a cavity in the bone to fill up, and that this operation did away with the necessity for the production of much granulation tissue.

Mr. W. I. DE C. WHEELER congratulated Mr. Pringle, and said he had an opportunity of seeing a good many of the operations performed, and had recently adopted the method in the case of a man suffering from chronic disease of the tibia, and although there was a fracture in the strip of the bone left it gave rise to no trouble afterwards. He was extremely interested in the resection of the bone, as he had been carrying out this in children. He pointed out that he had demonstrated that the periosteum does form bone in children, and the process can be seen in X-ray photographs.

Mr. CRAWFORD said that he was particularly interested in the case where the disease spread to the epiphysis, as he had experience of four cases in which he found that the dead bone extended to the end, and that in every case there was a large cavity. He mentioned that in one of the cases he had to operate three times, and that it took from one to two months to heal.

Mr. STOKES asked if there were any cases recorded in which the periosteum failed to reproduce bone.

Mr. BLAYNEY remarked that in the cases referred to it would be almost impossible to test the periosteum, as it was difficult to peel it off without bringing away some scales of bone with it.

Mr. PEARSON said he thought the periosteum was to be regarded as bone surface. He recalled a case in which there was no necessity for peeling off the periosteum at all, and the entire wound was healed in four weeks. There were no scales in that periosteum, and the X-ray photographs, taken five years afterwards, showed complete re-formation of bone.

Mr. PRINGLE, replying to the remarks, said he thought that in childhood there was a certain number of osteo-blasts lying in the periosteum. As a matter of fact, in the case shown when the upper end of the shaft was cut it pulled itself out, but chips of bone might have been left. There was no doubt that in some cases the periosteum failed to regenerate bone. This was possible in very chronic tubercular cases, as the osteoblasts might become destroyed, but in the majority of cases the periosteum seemed to regenerate bone. He had seen Mr. Wheeler's cases, and it was agreed that there was slight shortening. He had no hesitation in removing the whole strength of the bone in young persons if he could not find a normal strip. In one case he had a fracture but it reunited, and there was some shortening. Referring to Mr. Crawford's difficulty, in a great majority of such cases he had seen chronic inflammation of the knee joint, and in one such he had endeavoured to fill in the cavity by pushing in the tissue to facilitate healing.

NOTE OF A CASE OF STONE AND TUMOUR IN THE SAME KIDNEY.

Mr. C. ARTHUR BALL described a case in which he had removed a kidney with a tumour and a stone. He stated that the patient, a man, æt. 45, had complained for two years of a more or less continuous pain in the region of the right kidney. On two occasions he had passed blood, the first about two years ago; the second a few days before he came to town for treatment. *On examination.*—The only point of note was a slight but decided tenderness when the right kidney was palpated. The urine contained no blood, pus, albumin, or tubercle bacilli, and beyond a few uric acid crystals nothing abnormal was made out microscopically. An X-ray examination showed a small calculus in the pelvis of the kidney. The kidney was, therefore, exposed by an extra-peritoneal incision with a view to removal of the stone, and a tumour was found on the convex border of the kidney, which was therefore removed with the stone *in situ*. The tumour was microscopically a cystadenoma.

Mr. WHEELER asked if the incision which Mr. Ball had described some time ago was used in this case. He mentioned that he had found it most satisfactory recently.

Mr. PRINGLE, referring to the difficulty of passing the catheter past the brim of the pelvis, said this was a difficulty which was commonly met with in a normal ureter and had no significance. He suggested that if the catheter met with a stone the patient would experience pain. He mentioned a case in which he removed a calculus and the left kidney, and some years afterwards the patient came back with calculus in the right kidney. The calculus in the right kidney afterwards recurred and was again removed. He had seen the patient again, and thought it probable that he had another stone, but he did not intend doing another operation, as he considered that a certain amount of kidney was destroyed each time.

The PRESIDENT remarked that it was very significant how long life may be prolonged while there is even a small healthy portion of the kidney left to secrete urine.

Mr. BALL, replying to the remarks, suggested that Mr. Pringle should take the remaining stone out of his patient's kidney, as he had experience of a case in which the operation had been done three or four times without doing the patient any harm. In the case reported he made an anterior lumbo-iliac incision for the removal of the stone.

INTESTINAL EVACUATING TROUGH.

Mr. H. DE L. CRAWFORD demonstrated an intestinal drainage trough planned as an effectual means of quickly emptying intestine distended with gas and fæces while preserving the surgeon's gloves and the patient's peritoneum from contamination. The apparatus consisted of a metal trough closed at one end by a strong rubber dam, the other leading into a funnel attached to a long piece of rubber tubing. Two long intestinal clips rested in notches cut in the wall of the trough, and the whole was supported on two flat plates of metal. A hole was cut centrally in the dam and the assistant pressed a distended loop of bowel against this from the outside, so that a portion of the wall protruded into the vessel. The operator caught this protrusion with the intestinal clips and secured it by slipping their handles into the notches, thus stretching the rubber and providing a water-tight contact. The intestine was then emptied and the cut sutured, using a needle holder and tying the sutures with a forceps so that there was no risk of infecting the gloves.

The PRESIDENT congratulated Mr. Crawford on the contrivance.

Mr. W. I. DE C. WHEELER said that every surgeon recognised that there was a want for an apparatus of this kind and he considered the idea a very good one, but, of course, he would like to try it several times.

Mr. STOKES mentioned the use of a football bladder and Murphy's button for the same purpose.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD AT THE WEST LONDON HOSPITAL, FRIDAY, JANUARY 16TH, 1914.

The President, DR. F. S. PALMER, in the Chair.

THREE short papers were read on the subject of "Congenital Abnormalities."

DR. ARTHUR SAUNDERS discussed abnormalities from the medical side.

Mr. N. BISHOP HARMAN read a paper on "The Inheritance of Congenital Defects," and

Mr. OSWALD L. ADDISON read a paper on "Some Common Surgical Abnormalities."

The following cases were shown:—

Dr. F. S. PALMER: Case of congenital heart disease with residual hemiplegia.

Dr. W. MACADAM ECCLES: (1) Case of syringomyelia and acromegalia combined; (2) case of spina bifida occulta; (3) case of meningo-myocele (operation; subsequent hydrocephalus).

Dr. ARTHUR SAUNDERS: Case of congenital mental deficiency—mongolism, cretinism, microcephaly, hydrocephaly.

Dr. GEORGE PERNET: (1) Diffuse nævus in a boy; (2) supernumerary fingers in a boy; (3) a case of spacing and notching of upper incisors.

Dr. J. F. HALLS DALLY: Two cases of congenital heart disease.

Dr. HAROLD PRITCHARD: A case of congenital heart disease.

Mr. N. BISHOP HARMAN: Cases and drawings illustrating congenital defects of the eye.

Mr. O. L. ADDISON: (1) Case of Sprengel's shoulder; (2) case of occipital meningocele with Sprengel's shoulder; (3) congenital hydrocephalus with occipital myocele and supernumerary thumb; (4) case of congenital scoliosis; (5) case of congenital deformity of femur and absence of upper third of fibula; (6) congenital dislocation of rudimentary patella.

Dr. A. C. D. FIRTH: Case of congenital scoliosis due to extra half vertebra.

Mr. H. TYRRELL GRAY: (1) Case of gigantism of the left leg, talipes equinovarus in the right leg and vascular abnormality; (2) congenital club hand with rudimentary thumb and absence of metacarpal bone; (3) mild phocomely with other deformities; (4) clinocranial disostitis.

Dr. STANLEY WYARD: Case of congenital absence of the bile ducts.

Dr. F. SHIRWELL DAWE: A case of desitio cardia.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JANUARY 21ST, 1914.

The Vice-President, MR. J. M. B. HODSDON, in the Chair.

DR. GOODALL demonstrated a modified trocar and cannula. The cannula was constructed to carry a piece of rubber tubing and the trocar was prolonged for an inch between the cannula and the handle so that about an inch of tubing could be attached to the cannula before it was inserted. The rubber tube could be compressed while the cannula was being withdrawn. To this rubber tubing either a syringe, an aspirator or another length of tubing could be readily attached. A metal case was screwed on to the handle when the instrument was not in use. The makers were Messrs. Gardner and Son, Edinburgh.

Mr. SCOT SKIRVING showed a vesical calculus about the size of a swan's egg. It weighed 11½ ounces. It had been adherent to the floor of the bladder of a girl æt. 16.

Mr. J. M. GRAHAM read a paper on

CANCER OF THE APPENDIX.

He had investigated 11 cases. Eight were spherical-celled cancer and two were spherical with only a few columnar cells. Only one case was adeno-carcinoma. The spherical-cell cases had all occurred in patients under 30 years of age. They were benign in nature as regards metastases. The adeno-carcinoma occurred in an older patient and metastases were present. This was in accordance with the published findings in such cases. A yellow coloration was a feature of the cases. Spread to the cæcum did not readily occur in the spherical-cell cases.

Professor CAIRD said that the condition was rare. He had cut every appendix he had ever removed from end to end and had only met with it in two instances. The coloration was a striking feature. In one case the appendix had been glued to the cæcum, and yet no invasion of the cæcum had occurred.

DR. CHALMERS WATSON gave a communication on

INTESTINAL TOXÆMIA,

with special reference to the indications for operative treatment. He remarked that the importance of intestinal toxæmia as a cause of chronic disease was greater than was generally recognised. The clinical groups into which such cases fell were neurasthenia, rheumatoid arthritis, and a dyspeptic group which included cases with symptoms resembling those of chronic appendicitis, or gall-stones. In many of these cases the primary lesion was in the cæcum and ileum. There might be dilatation, displacement and adhesions. A number of lantern slides were shown illustrating the course of bismuth meals at intervals after they had been swallowed.

The following general conclusions were stated:—

1. The diseases under consideration are essentially medical conditions, capable of being cured by appropriate treatment if thoroughly carried out in the earlier stages of the disease; the question of surgical treatment should therefore seldom arise.

2. There are at present many advanced cases of these diseases in which prolonged medical treatment on the most modern lines produces little or no permanent benefit, and in which benefit may be looked for from appropriate surgical treatment, which effectively reduces the septic absorption from the large bowel. Examination by means of the X-rays gives information of very great value in these cases; special attention should be directed to the cæcum, ileum (terminal part), and duodenum, and the results should be studied along with the other clinical findings.

3. The operation of short-circuiting as recommended and performed by Lane is a simple one, but its nature is such as may readily lead to unsatisfactory results in less experienced hands.

4. Before any operation is decided upon, a prolonged course of medical treatment, carried out with great attention to detail, is indicated.

5. When these medical measures have failed to relieve, the operation of short-circuiting, as recommended by Lane, should be performed.

Prof. CAIRD said that many very slight causes might give rise to very obstinate constipation, and on the other hand apparent causes might be removed and yet the constipation remained. It was often difficult to ascertain and separate possible causes. He had seen cases where stenosis of the pylorus had given rise to local symptoms and had been associated with marked constipation. Relief of the stomach condition often cured the constipation. In a very large number of cases the surgeon might be led to expect adhesions, and yet found none; and, again, in the *post-mortem* room very marked adhesions and ileal kinks might be found, and yet there had been no history of constipation. It was clear that extensive adhesions might be present without any symptoms. Much more evidence was required about the effect of adhesions and constipation. He recalled the case of a servant girl with most inveterate constipation. She had been under treatment for a long time. The abdomen was opened, and everything appeared healthy, so the abdominal wound was stitched up. From that day she had never suffered from constipation again, and was now in perfect health. He thought the old method in vogue in the time of Hunter might be worth a trial. The patient was placed with the feet high up and the abdomen dependent. This might possibly favour the undoing of kinks and the passage of food along the intestine.

Prof. RUSSELL said that Professor Caird had thrown much light and brought much common sense to bear on an involved subject. The question depended so much upon the skill brought to bear in ascertaining upon what factor the patient's disturbed condition depended that it was difficult to know exactly what was meant by the description of different observers. He was not prepared to accept Dr. Watson's interpretation of many of the appearances his photographs showed. The passage of a bismuth meal was a different thing from the passage of food, and the passage of the meal depended to some extent upon the position in which the patient was kept after the meal had

been taken. In many cases, after a gastric condition had been corrected, symptoms of intestinal stasis had disappeared. Ptosis of the transverse colon was very common and might be extreme without any symptoms whatever. It was difficult to say how often and in what instances symptoms were to be attributed to ptosis or delay in the passage of intestinal contents. While it was imperative to maintain a regular action of the bowels, there were numerous neurasthenics who were not benefited by any amount of clearing out of the bowel. The importance of absorption of bacterial toxins from the relatively dry contents of the colon had been greatly exaggerated. Too definite statements had been made. A little might be known about the aerobic organisms of the bowel. Nothing had been done in connection with the anaerobic bacteria. While recognising that neurasthenia and rheumatoid arthritis might be benefited by rigid attention to diet and the action of the bowels, it by no means followed that all cases of neurasthenia and rheumatoid arthritis were determined by bowel conditions. He agreed with Professor Caird in regard to kinks and bends. The hepatic and splenic flexures had acute bends, and yet the rectum was easily filled with bismuth. In cases where the intestine showed ordinary mobility he was a profound sceptic about the advantage of anchoring the cæcum and he was a sceptic about the harm done by kinks.

He had seen cases after a short circuiting operation where there had been difficulty in the passage from the ascending colon further than the short circuit. In neurasthenia with general splanchnoptosis short circuiting did no good, and it was a question whether the colon was the point to be attacked. Gastro-enterostomy would in many cases do more good.

Dr. SPRIGGS said it was a matter for the future whether the significance of intestinal toxæmia might be much restricted. He showed a series of slides illustrating bismuth meals at different stages of their passage. He said that the previous administration of castor oil made no difference to the behaviour of the meal, but if the patient were constipated it was an advantage to give it as it could not be given again till the observations of the meal had been made.

Sir JAMES AFFLECK said he had come to hear about intestinal toxæmia, but had heard very little about it. Granting that the pictures showed all that had been attributed to them, how did intestinal toxæmia arise? There must be a defensive mechanism to prevent the ill-effects of absorption from the bowel. Toxæmia could only occur when this mechanism broke down. The breakdown could be easily traced in some cases, as when a liver abscess followed a fæcal ulcer.

Bacterial and chemical action accounted for a great deal of intestinal toxæmia, but the vitality of the intestinal wall was an important point, and must be considered. In regard to kinks and adhesions it was wonderful how nature adapted itself to difficulties. Tumours might press on the intestines yet the bowels moved regularly, and he thought that Nature could deal with kinks without surgical aid. He thought that modern surgery had made physicians a little less patient in the elucidation of problems than they used to be.

Dr. MACGILLIVRAY said he wanted information on intestinal toxæmia associated with colitis, but he had received no information on this point or on intestinal toxæmia in general. He looked upon the wall of the alimentary canal as a filter, and as long as the mucous membrane was healthy there might be any number of bacteria in the canal without ill-effect, but if the wall were unhealthy toxæmia resulted. A purge removed the toxins, but irritated the bowel. If the toxins were not removed, the bowel lesion and the toxæmia increased. He wished that practical treatment had been more adequately dealt with.

Dr. TORRANCE THOMSON thought that intestinal stasis was often a local condition due to a general cause.

Mr. GEORGE CHIENE thought that anchoring the cæcum as a surgical principle was wrong. Lane's operation often led to prolonged diarrhœa, and frequently to regurgitation of the contents of the small intestine into the transverse colon. Anastomosis into the transverse colon gave the advantages of the operation without the disadvantages.

Mr. DOWDEN said he had done short circuiting operations with little benefit, and thought the whole subject was associated with conditions which were not yet understood.

Mr. STRUTHERS said that we still wanted to know the state of affairs after a bismuth meal in normal conditions. Dr. Watson's interpretations were in several instances open to objection. Adhesions were found frequently in all sorts of conditions, and many of them were anatomical conditions. He had found a marked Lane's kink in an eight months' fœtus. He had seen acute symptoms arising from a Jackson's membrane, and if acute symptoms could arise why not chronic? The conditions, however, in the great majority of instances were not such as to give rise to any delay in the passage of intestinal contents. He had done short circuiting operations in tuberculosis of the bowel, and had always regretted it. A dry, solid residue tended to accumulate in the ascending and transverse colon due to regurgitation, and he did not think that there was a hopeful future for short circuiting operations.

Mr. CARMICHAEL agreed with Mr. Struthers, and said that the more he saw of X-ray photographs the less stress was laid upon them as indicating the position of the bowel and the rate of transmission of food through it. He had often seen bands without any evidence of delayed transmission. Many cases where symptoms persisted after division of bands were really examples of cæcal colitis. Anchoring and reduction of the cæcum were not advisable procedures, and it was better to remove the colon.

Mr. WADE said that many cases of intestinal stasis were not curable by the physician. Some form of short circuiting was probably required. The cæcum was often so large that it was unable to drive on its contents, and in these cases he thought the best operation was to reduce its size.

Mr. WILKIE said that Lane had shown that improvement followed short circuiting or colectomy. The subject required much more full investigation. In toxæmia what was absorbed? That stasis should cause definite disease was known. It was known that it might cause duodenal ulcer. He thought that reduction of the size of the colon was often of service. It might be too large to empty itself against gravity, and the reduction was an easy operation.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE annual meeting was held in Manchester on January 16th, 1914, when Dr. Willett (Liverpool) was elected President.

Dr. W. E. FOTHERGILL (Manchester) described a case of

FATAL TOXÆMIA OF PREGNANCY,

complicated by vesicular degeneration of the chorion. A woman, æt. 26, was admitted as an urgency during the seventh month of her third pregnancy. She was delirious. The abdomen was enormously distended by free fluid. The legs and labia were much swelled. The urine contained a large quantity of albumen. The os was closed, and there had been no bleeding. It was dilated under ether and the hydatid mole was then diagnosed. The fluid having been removed by an abdominal incision, supravaginal hysterectomy was rapidly performed. The uterus was the size of one eight months pregnant. Its wall was everywhere very thin, but it was not perforated by villi. The whole cavity was filled with vesicles of degenerated chorion. The ovaries were normal. The patient improved for a time, she became rational, took food well, and was free from œdema and hydroperitoneum. Later the toxæmia from which she was suffering on admission regained the upper hand. The legs and labia again swelled, and the abdomen once more became filled with fluid. The delirium returned, albumen reappeared in the urine, and the patient died 27 days after the operation. Unfortunately no *post-mortem* examination was permitted.

Dr. HOWIE SMITH (Stockport) showed a

UTERUS DIDELPHYS,

both horns of which have been pregnant at separate times. After giving birth to a macerated premature fœtus, the placenta was adherent, and the patient died of shock. The uterus was in two completely separate halves, which were only joined between the cervices. One half had been pregnant some years previously and the cervix was much hypertrophied; the other was the one from which the recent child had been delivered.

Dr. LEITH MURRAY (Liverpool) read a note on

THREE CASES OF PYELITIS DEVELOPING AFTER DELIVERY.

The cases were atypical (1) in presenting no localising signs or symptoms, (2) in showing a "continuous" fever, (3) in the small amount of pus present in the urine of patients rather seriously ill, and (4) in the onset on the day following delivery. He was inclined to think that this type might contribute to puerperal morbidity more largely than was thought. The condition easily eluded diagnosis if the urine was not centrifugalised. Vaccines were of marked service when intelligently administered. The action of urotropin, aided by acid sodium phosphate should always be controlled by an investigation of the formalin actually formed in the urine. The larger doses of Thomson Walker were strongly recommended.

MEDICO-LEGAL SOCIETY.

MEETING HELD JANUARY 20TH, 1914.

AN adjourned discussion of a paper (by Dr. Robert Armstrong-Jones, of Claybury Asylum) upon the urgent need for legislation to permit of the

TREATMENT WITHOUT CERTIFICATION OF EARLY CASES OF INSANITY,

the so-called incipient insanity, was opened on January 20th last at 11, Chandos Street, Cavendish Square, W., under the chairmanship of Earl Russell, by Dr. C. HUBERT BOND, one of the Lunacy Commissioners, who pointed to the need for safeguarding early cases of mental disease against those persons desirous of making money out of their affliction. He referred to the shame felt by the friends of mental cases when it was necessary for them to undergo treatment, and the need for privacy which tended at times to overshadow the patient's welfare. He suggested that the term "incipient" would need to be carefully defined to prevent abuse, and it must possibly have application to a time limit from the first onset of the symptoms, and to apply to the first attack or only the early stages of subsequent attacks. He was against an official list of Homes, as this might tend to the extension of licensed houses, and he was not officially in favour of what has been described as "single care"—particularly if a definite line of treatment had to be followed. He expressed the sympathy of the Lunacy Commissioners with the desire for greater freedom to treat mental cases in their earlier stages, but with due safeguard against abuse.

Dr. JOHN CARSWELL described the system in vogue in Scotland for the poor insane, and pointed out the closer connection between lunacy administration and that of the Poor Law in Scotland than in this country. In Scotland it is also permissible to treat cases of insanity in private homes for a period up to six months without certification, but with notification from the medical attendant that this course was desirable in the interests of the patient.

Dr. JAMES DEVON, one of H.M.'s Prison Commissioners for Scotland, also spoke of the necessity for recognising the need for early treatment and the advantage to the sufferer if this could be done without sending him into the asylum.

Dr. F. S. TOOGOOD described how much was being done in the Lewisham Infirmary under the present law, which admitted a needy case into the Poor Law Infirmary, and where such a case could be treated for 28 or 31 days under the present Lunacy Law. He stated that nearly 50 per cent. of all the cases got well within that period, and were thus saved from the stigma of the Lunacy Certificate, which implied a money saving also to the Guardians, who were thus freed from the expense connected with certification, removal, and maintenance of the patient during detention in the asylum.

Dr. HENRY RAYNER quoted his experience in the out-patient department of St. Thomas' Hospital, and was entirely in favour of a change in the law, which he himself had been advocating for many years.

Mr. P. T. BLACKWELL urged that greater freedom should be allowed in treating mental cases in the early stages, and his remarks were supported by Mr. M. J. FINUCANE. Dr. C. T. EWART warmly supported the scheme, and Mr. H. F. KEENE, the Clerk to the Asylums Committee of the London County Council, related what had already been done by his Committee, and he outlined the proposals in respect of treatment in the new Handsley Hospital. Sir WILLIAM T. COLLINS ably summarised the discussion in a clear, eloquent and practical speech, and Dr. ROBERT ARMSTRONG-JONES replied. The following resolution was then formally proposed by EARL RUSSELL, and unanimously agreed to: "That this meeting of the Medico-Legal Society is of opinion that early treatment of incipient insanity without certification will be advantageous, and that the Council be authorised to take such steps as they may think necessary to support legislation to effect this object." There was a full attendance of members and others, among whom were Sir John Tweedy, Sir Victor Horsley, Dr. Sydney Coupland, Mr. W. C. Clifford Smith, Dr. Helen Boyle, and others.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 24th, 1914.

SACRO-LUMBAR ANÆSTHESIA.

LOCAL anæsthesia through the rachis has been practised for several years for operations on the pelvis and the lower extremities, the point chosen being that of the space between the fourth and fifth lumbar vertebræ. Jonnesco, of Bucharest, advocated the dorsal or even the cervical region for operations on the upper part of the body

Dr. Le Filliatrie, chief surgeon of the Paris Prison Infirmary, is opposed to all of these methods, none of which, in his opinion, can run into general practice, as the first produces only anæsthesia of a certain portion of the body, while the two others were dangerous, as they exposed to wounding the cord.

For him, rachianæsthesia is only practical where it permits the surgeon to obtain general anæsthesia of the patient, avoiding thus the dangers of the usual narcotics.

Here, however, it is first necessary to establish an anatomical point, always the same, clearly and easily determined, situated as far as possible from the end of the cord, allowing easy penetration into the arachnoid cavity without wounding the roots of the cauda equinis, and permitting to obtain general anæsthesia. All these desiderata constitute, in his opinion, the fundamental principles on which the method of rachianæsthesia should be based. This point is the sacro-lumbar space. Since Dr. Le Filliatrie has employed it for his operations he never observed the pain radiating down the thigh so frequently complained of after puncture of the fourth lumbar space.

The patient being in a state of fasting, the needle is inserted beneath the spinous process of the fifth lumbar vertebra, slightly outside the median line and a certain quantity of the cephalo-rachidian liquid is withdrawn; 15 cubic centimetres for anæsthesia of the body and upper extremities, 20 c.c. for the head and neck, 10 c.c. for the pelvis and lower extremities. Then 3 c.c. of a solution of cocain (1-50) prepared on the spot, are injected, through the cannula, while a hypodermic injection of 2 milligrammes of sulphate of strychnine and 5 centigrammes of spartein, is made

into the thigh. The patient is then placed in the reclining position, with the head slightly raised on a cushion. He is instructed to cough for five or six minutes in order to aid in the diffusion of the cocain solution in the cephalo-rachidian liquid.

At the end of ten minutes or a quarter of an hour anæsthesia is complete from the summit of the head to the sole of the foot. A slight nausea may follow for a few minutes, but is never of any consequence.

The patient preserves, with normal respiration, his mobility, his reflexes, all his intelligence, and can distinguish between hot and cold, but without feeling the slightest sensation of burn

The duration of the anæsthesia varies from one (head and neck) to three hours (lower extremities). A few hours after the operation the patient can take food.

During the last twelve years the author practised by this method 2,837 operations without one accident. Of these 1,144 were practised since 1909, divided into 248 above the umbilicus and 896 below that line. As to the nature of these operations, 452 were laparotomies; among those concerning the head and neck may be mentioned craniotomies, total ablation of the tongue, enucleation of the eye, thyroidectomy, ablation of the larynx, etc.

Among the advantages of this method Dr. Le Filliatrie mentions: entire absence of vomiting, hence absolute immobility of the head and neck and complete silence of the abdomen. A shield being placed before the face of the patient, he is not disturbed by the presence of the operators, nor by the sight of the instruments; he is docile in the hands of the surgeon, who can thus fix all his attention on the operation, and is also entirely relieved of any anxiety as regards the narcotic.

The operation terminated, the general condition of the patient is found unchanged; in other words, he is physically and intellectually normal; there is no shock nor after-vomiting. The integrity of the liver, kidneys, supra-renal capsules and the digestive tract is preserved.

For patients suffering from cachexia, albuminuria, heart disease, and for aged persons, this method of producing general anæsthesia, concludes Dr. Le Filliatrie, is certainly the best.

HÆMORRHOIDS.

Applications twice a day of lead lotion; each month take two pills daily of

Ext. of Capsicum, 1 gr.
Ext. of hamamelis, 1 gr.
Ext. of hydrastis, ½ gr.

If the piles are turgescent, rest in bed and application of

Solution of adrenaline, 1 dr.
Water, 4 oz.

If painful, place a suppository night and morning.

Ext. of belladonna, ½ gr.
Cocaine, ½ gr.
Ext. of hamamelis, 1 gr.
Aristol, 3 grs.
Cacao butter, ½ dr.

In case of much bleeding, small enemas of cold salt water or

Chloride of calcium, 3 drs.
Water, 6 oz.

GERMANY.

Berlin, Jan. 24th, 1914.

AT the Verein für Innere Medizin, HR. Stettiner showed some

CASES ILLUSTRATIVE OF SURGERY IN CHILDHOOD.

He laid stress on the peculiarities of surgery during early life both in regard to the indications, the preparations necessary before operation, and also regarding after-treatment. There were still divergencies of opinion in regard to operation in acute diseases, one of these in regard to operation in empyema. At a late meeting in Vienna he and Buttermilch had both opposed the views of others that operation was to be rejected altogether in early life. He showed two Röntgen illustrations of the regeneration of bone after resection of ribs. Both the children from whom the plates were taken had been operated on during the first year of life and with success. One of the plates taken six months after the operation showed a marked development of callus. The second one, taken 3½ years after operation, showed, as the sole residuum, nothing but a slight diminution in the size of the bone. Another preparation from a section from an infant four weeks old which had been operated on for appendicitis showed that the disease was to be met with from the very earliest infancy. The speaker remarked on the difficulties of diagnosis in very early life, the result of which was that the cases were very frequently sent into hospital too late for operation. In the first place, in abdominal disturbances in infants under four years old the first thought would be of invagination, as appendicitis was rare at that age. Here also he advocated early operation when no success had been obtained from injections of water from a height or insufflation of air. The speaker then alluded to four cases of atresia ani. In one case the blind end was so high up that it had to be sought for through an incision into the abdomen, when several other atresias were found. Naturally, almost, the case ended fatally. The second case was operated on the day after its birth; the child was now nine years old. Two years ago a second operation had to be performed, as the sphincter ani closed only imperfectly, so that a plastic operation had to be performed, making a sphincter out of the gluteus muscle. Since then the boy, who was a good scholar, had been able to retain his motions. The question of the efficiency of the sphincter in these operations was one of great importance. It was not easy to determine with certainty how the new sphincter would act. In the third case—atresia ani vestibularis—operated on at the age of three months, he hoped the sphincter could be retained. This could only be determined with certainty later on. On account of this uncertainty in a fourth case he had refrained from operation, and later on would recommend the wearing of a bandage.

He next showed a number of cases of hypospadias penis. Here the aim of operation was to provide a normal opening for the passage of urine, and later on a sexual organ capable of exercising its proper functions. In regard to the latter point, the first thing to attempt was to give a proper direction to the penis; this should be done as early in life as possible. In slight cases the operation of Beck was the most suitable. He then showed a case in which the penis was completely grown to the skin of the scrotum. At the first operation the necessary separation was made (the infant was again three months old). To bring about a normal-looking organ a series of further operations would be required—first, giving a normal direction; second, the provision of a penile urethra, after making a provisional opening into the perineum. A number of ways of forming a urethra had been proposed—transplantation of the saphena vein, as he himself was the first (but almost simultaneously with Becker and Tanton) to carry out, or transplantation of the vermiform appendix; transplantation of a ureter or one of the older plastic operations could be performed, but this should not be attempted until the child had reached its sixth year. A good deal of patience was required in these complicated cases if the end aimed at was to be reached.

AUSTRIA.

Vienna, Jan. 24th, 1914.

ALCOHOLISM AS A NEUROSIS: PROPHYLAXIS BY EDUCATION.

AT the recent meeting of the International Verein für Medizinische Psychologie und Psychotherapie held in Vienna, Dr. Strasser (of Zurich), in the course of the discussion on alcoholism, made a communication on the character and disposition of dipsomania and its victims, and the influence of education in the prophylaxis and therapeusis of the same. He there pointed out that nearly all that had hitherto been attempted in this direction—and it could not be denied that very considerable results had been achieved—had failed to reach the fundamental basis of the condition;

and this fact was due to the maintenance of the one-sided view that the condition of dipsomania constituted, by itself, a complete clinical picture of an existing disease. In this way the great fact is overlooked that this morbid craving for drink is really an external symptomatic presentation of a condition which has been structurally evolved from the continuous basis of the mental life of humanity; and that, while resting on such basis, as it necessarily always does, it must have its past and its future, as well as its present intuitive activity. This reflection may, indeed, lead us to the conclusion that the treatment of juvenile alcoholic subjects should be left in the future in the hands of the pedagogues. But, without further investigation and experience in this department, we cannot confidently distinguish the individual specimens, among groups of children, who are destined to become the alcoholics of a later stage of life. The unhealthy features of the alcoholics of later life show us, nevertheless, that their characteristic aspects in advanced age are really but exaggerated presentations of those which were present before their abuse of alcohol had commenced; and, as such, are to be rated as those of a neurotic, as contrasted with those of a perfectly healthy child. When the pedagogue has to deal with the nervous character of the child, he needs, for the above-mentioned reasons, no reflection as to whether the individual specimen before him is destined to be a victim of neurotic anguish, or whether he is likely to have recourse to the abuse of alcohol as a narcotic or as an artificial aid to activity. The principal consideration in all such cases is that he should comprehend the child before him. But everything is not completed with this comprehension. There are various ways and means to be considered now which the psychological schools of the present day have taught the pedagogues—such, for instance, as those afforded by "suggestion" and "analysis"—which carry with them the same defects: that they reduce the reliability of the self-regulating equilibrium of the human understanding, bringing it down from a stable to an unstable condition, from a state of immobility to one of mobility. The only pathway through which a lasting impression can be made on the psychological mechanism of the child is that of intuition, of intellectual association. This view, indeed, forms the groundwork of the Bergsonian philosophy; as it does, independently of this latter, and on therapeutic grounds, the guiding clue of Alfred Adler's science of character—of the investigation of the psychology of the individual. If the pedagogue has once entered on this pathway of progress, and placed himself in internal sympathy with the aims of the future life of the child, he can then, for the first time, so prepare the educator that, although he may be deceived in his estimate of the child's constitution and the influence of his own function thereupon, he may still succeed in his educational efforts, not so much with the coming period of youth as with that of adult life, thus securing by his intervention in effecting a remodelling of the child's life schemes, and converting a child naturally predisposed to dipsomania to a constitutional frame of mind, in which the use of alcohol may be safely adopted, upon occasion, in its function of an artificial aid instead of as a symptom of a neurosis.

Sympathetic Sensations.

Dr. Birker (of Vienna) discussed the subject of sympathetic sensations. These are an expression of the collective functional unity of the whole cerebral cortex, in regard to the effect of the reaction which is elicited by a sensation-stimulus. Such a stimulus may disengage simultaneously many sensations, of individually varied specific qualities, each one of which appears to be a function of the others. Among those sympathetic sensations the most conspicuous *rôle* is manifested in the photisms elicited by sound impressions (coloured audition, tinted hearing); these are of so special physiological and pathological interest as to present a worthy claim to a more widespread attention than what they have hitherto received.

HUNGARY.

Budapest, Jan. 24th, 1914.

AT the recent meeting of the Budapest Royal Medical Society, Dr. Wiesner read a paper on

Acute Dilatation of the Stomach.

He remarked that the frequency of acute dilatation of the stomach as a post-operative complication has brought it into the limelight in the last decade, but cases due to overfilling of the stomach were described centuries ago. He tabulated twelve post-operative cases from recent Hungarian and Austrian literature, and mentioned three from Germany and two from Norway. Dr. Wiesner encountered one case himself, and gives the details of this and of twelve other cases at different hospitals. The patients were five women and eight men, æt. from 15 to 37; four were healthy when the acute dilatation occurred, and in two other cases the dilatation occurred alter an operation on the knee and shoulder respectively. All the patients died in from one to five days. The correct diagnosis was made only in four cases; in one the trouble was supposed to be poisoning from the antiseptic that had been used. In the others, colic, ileus or peritonitis was assumed. It seems to be the general rule that the first case, at least, of acute dilatation of the stomach that occurs in a hospital is never recognised as such. He lays great stress on careful preparation for operations and careful diet during convalescence from acute diseases, especially typhoid, as important in prophylaxis. If the dilatation has occurred, rinsing out the stomach, resting it completely afterward, and stimulants, especially saline infusion, are the main points in treatment. Several professors advocate lavage of the stomach three times a day as the general rule. It may be necessary to raise the pelvis to facilitate the outflow of the fluid. Placing the patient in the ventral posture has proved effectual in the experience of some clinicians, but in Rosenthal's case harm resulted, and Borchards has reported aggravation of symptoms from the "cow position" (*Lavage a la vache*) recommended by Albrecht. Landani, Wiesner quoted, compares this position treatment with taxis in hernia. Kelling recommends raising the pelvis, the patient lying on the left side. Engström suggests that possibly good might result from introducing a speculum into the vagina, suddenly spreading it, and thus pushing the intestines out of the small pelvis. Dr. Hanssen, of Denmark, has reported success in some mild cases with faradisation and Erdmann with cold packs. Atropin has been recommended, but the reader protests that this has a weakening influence on peristalsis. In an operative case reported by Lennander and one by Sommarin, the acute dilatation of the stomach was found accompanied by volvulus of part of the small intestine. In an additional case reported by Wiesner, in which the acute dilatation came on a few days after a fibrosarcoma operation, the symptoms subsided under lavage of the stomach and saline infusion, but there was an acute exacerbation some days later and necropsy disclosed volvulus of the jejunum. Kehr and Tschudy, among others, have been successful with gastro-enterostomy, but most writers warn against operative interference. An early diagnosis and prompt measures for relief will generally forestall the necessity for an operation.

The Treatment of Foreign Bodies.

Dr. Bleyer has been studying the cases reported in the literature of the spontaneous expulsion of foreign bodies either by mechanical or bacterial means, and supplements the lessons thus learned by conclusions drawn from personal experimental research on the ultimate expulsion of foreign bodies incorporated in rabbits. When a foreign body is implanted in the tissues, the means to prevent its expulsion are strict asepsis, a compact rather than porous composition, or, if the foreign article is porous, it should be impregnated with an antiseptic. This induces a transient chemical suppuration which aids in walling off the foreign body; coating with vaseline or paraffin like-

wise answers this purpose. The bowel functioning must be regulated before and after the operation to prevent the intestinal bacteria from starting a process leading to expulsion of the foreign body. Another important point is that the foreign body should never be implanted during fever; even tonsillitis should contra-indicate it. The foreign body must not slip around in its place; to insure proper conditions in this respect long immobilisation is strictly necessary. If this is impossible, the serous effusion bathing the foreign body should not be drained away but left to protect it. The incision should, therefore, be as far away from the foreign body as possible to prevent eventual fistula. The foreign body should be as smooth, light and small as possible, and it should be encapsulated before active motion with it is allowed, as in case of an artificial tendon.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PROPOSED LISTER MEMORIAL INSTITUTE FOR EDINBURGH.

THE preliminary arrangements for the erection of a worthy memorial to Lord Lister, which has been the subject of a great deal of private discussion between the University, the Royal Colleges, and the Carnegie Trustees, have now been made public. The Institute will incorporate, and to that extent supersede the Research Laboratory of the Royal College of Physicians, and will continue on a larger scale the work done by that Institution. The general idea is to create a large institute for the teaching of pathology and bacteriology, and for research, and to place the whole institute under the immediate direction of the Professors of Pathology and Bacteriology, the general management being in the hands of a Board consisting of representatives of the two Royal Colleges, the University and probably also of the Carnegie Trustees The University will make itself responsible for the teaching side of the Institute, while research will be under the whole Board. The scheme is so far under way that we are justified in supposing that it will eventually come into existence, and of the £100,000 required one quarter has been guaranteed by the University and the Colleges. The Carnegie Trustees are expected to come forward with substantial assistance, and with this lead subscription from the public may be confidently looked to to provide the rest of the money. So far, no decision as to the site of the Institute has been made public; indeed, it is not certain that a site has yet been agreed upon. When the Institute is completed it will form an adequate memorial to the work of Lord Lister, and one worthy of the city and medical school in which so much of his work was done.

EDINBURGH ROYAL INFIRMARY—WORKING-CLASS REPRESENTATION.

For some time past there has been a desire on the part of the more democratic bodies in Edinburgh that the representation of the working classes on the Board of the Infirmary should be increased. Some years ago, if we mistake not, representatives of the Trades Council were admitted to a seat on the Board, and now it is proposed to give places to representatives of Friendly Societies and Insurance Committees, etc. The question was under discussion at the recent meeting of the Court of Contributors, which consists of persons who contribute £1 or more annually, and which has the power of electing representatives on the Board, and which, by means of a committee, reports annually on the general report of the managers on the working of the Institution. The proceedings of the Court of Contributors are, as a rule, purely formal; it is only now and again, as in the present instance, that anything of special interest crops up. In the Committee's report concurrence is expressed with the managers' view that the Infirmary has strong claim on the Friendly Societies and Insurance Committes for a grant under Section 21 of the Insurance Act, and to this paragraph Sir W. S. Haldane, one of the Committee, took exception. In a letter to the Chairman of the Managers, he gives as his reason, broadly, that in return for the support of the Friendly Societies, the Infirmary should give them representation. The present Court of Contributors, he states, represents solely the provileged classes, and the new rules suggested by the managers, while they confer votes on large employers of labour, exclude small contributors and bodies of employees. At the meeting a motion was carried recommitting these new rules to the managers for consideration, keeping in view the suggestion that the number of managers should be increased. It was explained that, under the Infirmary's Statute, the Board of Management had only the duty of managing the Infirmary, and that any alterations in the constitution could be made only by the Court of Contributors. There is no doubt that the Infirmary board, as at present constituted, although it commands the fullest confidence of the public, leans to the side of conservatism (not necessarily in the political sense); on the other hand, what we have seen of the attitude of Friendly Societies and Insurance Committees does not lead us to wish that they should acquire too strong a controlling voice in the conduct of a large teaching hospital.

WORKING OF THE INSURANCE ACT.

A number of reports on the working of the Insurance Act in various parts of Scotland have now been issued, but as these deal mainly with purely local administrative details they are not of sufficient general interest to quote *in extenso*. Some figures concerning the administration in Edinburgh have been furnished. Since July, 1912, there have been 418 applications for sanatorium benefit, of which 40 have been given domiciliary treatment, 63 dispensary treatment, and the rest institutional treatment. The Victoria Hospital has been paid £4,521, and medical practitioners have received £81 for examination of patients and filling up Form Med. 2. There is a balance on the estimate of £1,332, of which about £135 falls to be paid to the Corporation. The estimated income on the medical benefit fund was £47,000; paid to panel doctors £32,074, and chemists £6,414. The Argyllshire Committee report that the estimate of administration expenses exceeds the estimated income. There is a surplus of £200 on the sanatorium fund. In North Argyll it is proposed to suggest to the Highlands and Islands Medical Service Board the erection of a central isolation hospital, the provision of a nurse for the Hillrandon district, subsidies of £500 to each local nursing association, provision for dental and medical treatment of scholars, cycle allowances for nurses, superannuation of aged parochial doctors, additional doctors, a motor ambulance, improved telephonic and telegraphic facilities, and the widening of a bridge at Connel Ferry—altogether a comprehensive list of wants. The Caithness county scheme is on similar lines. It suggests the utilisation of the hospitals at Wick and Thurso, the establishment of additional cottage hospitals, the settlement of trained nurses in outlying villages, arrangements for consultations by specialists, and the installation of telephones or telegraphs in all sub-post offices. There is also a plea for school clinics in Wick and Thurso. The Western Friendly Society, Glasgow, report that, thanks to the medical examination at entrance, and the selection of occupation of entrants, their sickness experience was less than half of the actuarial expectation.

BAILIE W. B. SMITH, the Chairman of Glasgow Corporation Committee on Air Purification, has been delivering a lecture on "The Need for Purer Air" at Caxton Hall, Westminster. The occasion was a meeting held under the auspices of the Institute of Sanitary Engineers. Bailie Smith pointed out the injury to health and even loss of life caused by bad air, especially during the winter fogs. He quoted the late Dr. Russell, Medical Officer of Health for Glasgow, who many years ago said that any city during winter was always in danger of a catastrophe if certain weather conditions prevailed, such as keen frost, still air, and fogs for days together. Most cities, the lecturer said, had at some time experienced such a cata-

strophe, and he instanced the large number of fatalities from bronchial diseases which occurred in Glasgow in the winter of 1909, and compared the death-rate of this city with those of seven of the next largest towns in Scotland, where the cold was equally intense, but where there was no fog at the same time. In conclusion he described the method used, in the scheme which was now being inaugurated all over Great Britain, for a systematic analysis of the air.

Dr. Chalmers, Medical Officer of Health for Glasgow, in a report to the Health Committee of the Corporation, states that the death-rate for the year 1913 was 17.2 per 1,000, as compared with 17.6 in the former area of the city in 1912. In 1913 the mean temperature was 2.2° higher, and the rainfall 4.63 inches less, and, associated with this, the death-rate from all causes during the quarter rose from 13.9 to 15.5 per 1,000, and the diarrhœal rate for the year from 405 to 605 per 1,000,000. The death-rate from the principal infectious diseases rose from 1.780 per 1,000 in 1912 to 2,253 in 1913. The chief sources of increase were whooping-cough and diarrhœa, which showed increases in their rates respectively equal to 435 and 200 per 1,000,000. 1,459 deaths were attributed to pulmonary tuberculosis, giving a rate of 1.413 per 1,000 of the population, as compared with 1.304 in 1912, this being 109 per 1,000,000 higher.

Some discussion has been taking place in the lay press here as to the insurance surplus: one paper mentioning it as an example of extravagant expenditure that some insurance committee were even allocating to the doctors the capitation fees of those insured persons who had not hitherto chosen a medical adviser. The fallacy of this criticism has, however, been pointed out, and that there is in fact no essential difference in position between the fees of the unallocated persons and of those who, having chosen a doctor, have not required his services.

BELFAST.

BELFAST HOSPITAL FOR SICK CHILDREN.

ON January 2nd the forty-first annual meeting of the members, friends and supporters of the Belfast Hospital for Sick Children, Queen Street, was held in the Institution. The report of the medical staff, presented by Dr. John M'Caw, stated that during the past year 585 patients were treated in the wards of the hospital; of this number 325 were medical and 260 were surgical. There were 42 deaths, 24 in the medical ward and 18 in the surgical ward. The number of operations performed was 225. In the out-patient department 4,622 new cases were registered, of which number 2,383 were medical, 1,593 surgical, 595 eye, ear, and throat and nose, and 141 dental; 894 operations were performed. The total attendance numbered 14,280. The unusually large number of 45 senior students are attending the classes conducted by the staff in the medical and surgical diseases of infants and children.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

SECRET REMEDIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whenever there appears a letter from me in one of the medical papers bearing upon the above-named subject, I invariably receive a batch of communications from members of the profession and the public. This bears witness to the widening interest which the question is arousing, and seems to me fully to justify the persistence with which the matter is kept to the front in your own journal. Two letters have come to me since the appearance of my last in the MEDICAL PRESS a fortnight ago. The first, from a practitioner, calls my attention to the advertising pages of one of the parish magazines published in his district. These magazines are issued by one of the greatest societies for the publication of church literature, and are used in various parishes with a local supplement. The pages display a fair sprinkling of quack advertisements, including some of the directly injurious sorts containing potent doses of morphia or alcohol; and there is one of an infants' food, which, according to the elaborate exposure made of it in the report of the Australian Royal Commission, contains nothing whatever except ground lentils. An infant fed exclusively on this stuff would die as surely as though its diet were so much bran or sawdust. I have advised my correspondent to call the attention of the publishing religious society to these advertisements, and, if possible, to let me see the reply. This, I might wager, will be to the effect that the advertisements all come through an eminent advertising agency, and as they all appear in most of the leading papers and periodicals it does not seem possible that any valid objection to them can really exist.

The second letter is more remarkable. It comes from one of the proprietors of a widely advertised skin cure—it is good for all, and cures most skin diseases. The share in this property has fallen into my correspondent's hands in the course of legitimate business, and he wants to know what harm can be done by the sale of what seems to him a simple remedy. This remedy also is described in the Australian report. It is a mixture of hard and soft paraffin with some cheap perfume and colouring matter—inert, worthless trash. Proof of tragic results which follow reliance on "simple remedies" of this kind will be found in the forthcoming report of the Select Committee. Whilst waiting my turn as a witness in the Committee room, I heard the evidence of Sir Malcolm Morris and Dr. Whitfield on quack cures in skin diseases. They explained, for example, that lupus, taken in an early stage, is curable; that after a certain period it passed beyond the reach of medical art, and they stated that cases were constantly met with in which, whilst relying upon useless remedies, patients had allowed their malady to pass into a mortal phase—a phase ending in death, but only after prolonged indescribable suffering and misery. Sir Malcolm Morris and Dr. Whitfield might have told a precisely similar tale about syphilis and cancer. To the patient syphilis is largely a skin disease; but unless the nature of the malady be recognised in time and scientific treatment be applied and persisted in, the case may go from bad to worse and end in death, perhaps from extensive disease of the bones, perhaps of the central nervous system—locomotor ataxia or general paralysis of the insane. Cancer often appears as a skin disease. It is often treated with quack remedies until beyond the help of the surgeon's knife. In every hospital, in medical and surgical wards, and in every special department, are to be found the victims of this trade in "harmless, simple remedies." The nature of the trade is known to leading newspapers, the majority of which share in the plunder derived from it, and by a joint conspiracy prevent the facts from being made widely known. It is a shameful scandal; it cannot be kept for ever from full exposure to the public view.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery,
Earlswood Common.
January 22nd, 1914.

OBITUARY.

MR. J. JEKEN, OF ELTHAM.

ONE of the oldest and most respected of the residents of Eltham passed away the other day in the person of Mr. James Jeken, of Barn House, at the age of 87. The deceased, who qualified as M.R.C.S. and L.S.A. in 1850, was educated at the University College, London, and commenced to practise at Eltham in 1858, rapidly finding his way into the genuine affections of all around him. After five years' residence in the parish he married Miss H. M. Lewin,

the daughter an old and well-known Eltham family. Mrs. Jeken enjoys remarkably good health, and, in spite of her grief, is still strong. Barn House has been the home of Dr. Jeken and his wife for the past thirty years, although they previously had several residences in Eltham. Their silver wedding was celebrated at the same house, and on a pleasant day in August last Dr. and Mrs. Jeken entertained on the lawn there a few friends who came to congratulate them on attaining their golden wedding.

Although a member of the old Eltham Vestry, and then for a time of the Woolwich Borough Council when it was first constituted, and a manager of the National Schools, Dr. Jeken avoided public work a great deal, and he never liked to engage in controversy. The immense amount of good that he accomplished in Eltham, in spite of the fact that he tried to do it by stealth, could not escape notice, and many will recollect the memorable occasion on which a public presentation was made to the doctor at the Public Hall. When he entered the carriage which was to take him home, the horse was taken out, and an enthusiastic band of his admirers drew him to his residence. His work in connection with the local hospital, too, will not be forgotten, and there are very few poor families in Eltham who have not some reason to respect his memory, for in the days of his professional activities his skill and labour were often expended without thought of other remuneration than the gratitude of those whom he assisted.

HENRY ALBERT REEVES, M.R.C.S., F.R.C.S.Ed.

THE death of Mr. Henry Albert Reeves, at the age of 73, has removed one of the earlier orthopædic surgeons. He was born in Calcutta, and went to school at St. Albans. He was educated professionally at the Middlesex Hospital, and became M.R.C.S.Eng. in 1865, and F.R.C.S. of Edinburgh in 1871. He became Demonstrator of Anatomy at the Middlesex and London Hospitals successively. In 1869 he was appointed Assistant Surgeon to the London Hospital, and later Surgeon to out-patients. As he did not take the Fellowship of the English College of Surgeons he was not promoted to the full surgeoncy of that Institution. He was attached to the East London Hospital for Children, Shadwell, but did his best work at the Royal Orthopædic Hospital. He also held the posts of Surgeon to the Women's Hospital, to the Central London Ophthalmic Hospital; and that of Lecturer on Anatomy to the School of Medicine for Women. Reeves was a kindly, genial, man, a chess player and a sound surgeon and a fine anatomist. His contributions to medical publications were numerous, and he wrote a book on "Bodily Deformities," "Human Morphology" and a "Treatise on Practical and Applied Anatomy." His wife was the well-known novelist, Helen Mathews.

REVIEWS OF BOOKS.

NORMAL HISTOLOGY.(*a*)

THE two parts of this work are bound separately. The author's intention is to make the first part available for non-medical microscopists. It gives a good account of all the more useful histological methods. The author apparently favours the freezing microtome and prefers to use solid CO_2 cartridges. The parts of the microscope down to the mechanism of the iris diaphragm are fully described.

Part II. contains 98 coloured plates showing 204 figures in illustration of histological sections.

The letterpress is mainly devoted to a description of the figures and in spite of its size the book does not serve as a text-book of histology. We failed to find any account of the bone-marrow or parathyroids and the blood is poorly dealt with. Some very beautiful illustrations of the central nervous system are shown, but there is no connected account of their relationships. Taken simply as an atlas and guide to the interpretation of microscopic structure the book has certain merits. It has suffered to some extent at the hands of the translator. He is seldom happy in his choice of prepositions, and the finical stylist will get a jar on nearly every page. On page 80, part I., we read, "Most every beginner is possessed with a dislike for drawing."

In part II. we meet with much unfamiliar terminology "Shelves" of true skin, "Clods of Nissl," and the central "piston" (core) of Pacinian corpuscles may serve as examples. Both volumes are furnished with a full index.

(*a*) "Normal Histology." By Rudolph Krause. Translated from the German by Philipp J. R. Schmahl, M.D. New York: Part I., Methods. Pp. 86. Price 5s. Part II., Plates and description. Pp. 406. Price 25s. London: Rebman, Ltd. 1913.

MASSAGE. (*a*)

THIS is a small work on massage translated from the German by Miss Elizabeth Gould. A short introduction is given on the general technic and procedure of massage. This is followed by a brief description of these principles. The chief value of the work, however, is to be found in the illustrations which number nearly 100 in all, and which have been carefully reproduced. As a guide to the medical man in the application of massage and in the selection of suitable methods, this volume will prove useful. The anatomy of the parts is briefly and practically stated so that the reader obtains first an intelligent appreciation of the why and the wherefore of his treatment. As there are only 88 pages, the greater part of which are claimed by the illustrations, there is little trouble in fully mastering the contents of the book in a very short space of time. We can strongly recommend this volume to our readers as a reliable treatise on this practical aid to treatment.

PATHOLOGISCH-ANATOMISCHER PRAKTIKUM. (*b*)

THIS is an excellent little text-book of the very important science which its author has undertaken to place before his readers in moderate space and in lucid terms. The headings are arranged in a way which presents a fair claim to the nearest approach to perfection; the language is always well chosen, and the proportion of space given to each subject is approximately proportional to the importance of the latter. The volume deserves every success as a handy manual and memoriser of morbid anatomy and pathology. The printing, paper and binding have all been chosen in such a way as to make a perfect pocket volume—the *vade-mecum* of former generations—and reflect corresponding credit on the eminent firm of publishers, to whom, we take it, the credit must be given in this department.

GOUT, ITS ÆTIOLOGY, PATHOLOGY AND TREATMENT. (*c*)

DR. JAMES LINDSAY'S little work on "Gout, Its Ætiology, Pathology and Treatment," is a useful compendium of current views on a disease the pathology of which is still under discussion. We call it a "compendium" advisedly, because the author, with a modesty unusual in the writers of monographs, obtrudes his own views very little, preferring to quote without criticising the opinion of others. The "it is said," "it has been held," "it is believed," therefore recur rather too frequently. He says, by the way, that tradition "stigmatises cider as a gout producer," but in France, at any rate, this particular beverage rejoices in an anti-gouty reputation, possibly because, as the author observes, it "produces no effect what-

(*a*) "Massage: Its Principles and Technic." By Max Böhm, M.D., Berlin. Edited, with an Introduction, by Charles F. Painter, M.D., Boston. Illustrated. Philadelphia: W. B. Saunders Company. 1913.

(*b*) "Pathologisch-Anatomischer Praktikum: für Studierende und Arzte." Von Prof. Dr. med. Richard Oestreich, Privatdozenten an der Universitat und Prosektor des Konijin Augusta Hospitals an Berlin. Urban & Schwarzenberg; Berlin & Wien. 1913.

(*c*) "Gout: Its Ætiology, Pathology and Treatment." By James Lindsay, M.D.Edin. London: Henry Frowde and Hodder and Stoughton. 1913.

ever in the production or maintenance of gout," which is equivalent to a verdict of not guilty. His literary style leaves something to be desired. There is a superfluity of such expressions as "the blood contains a saturated solution of urates" (whatever that may mean), a joint "involved with acute inflammation," "toxæmia *from* which it is difficult to accept the theory," "a precipitate of bi-urate which tends to be more copious in the joints *where there may be a shower of them*." Then, too, what does the author mean by saying that "the first attack of gout comes on quite *unawares*"? Or again, "the deposits in gout would not appear to be always composed of sodium bi-urate, but . . . . deposits of other nature cannot be properly regarded as gouty," which is contradiction in terms. It is unusual, too, to say that a patient "is able for her full diet."

Useful as a summary of current views on gout, we cannot say that it adds to our knowledge of the subject, but the volume contains a number of excellent illustrations of the appearances presented by the victims of the gouty diathesis.

MEDICAL NEWS IN BRIEF.

Medical Sickness and Accident Society.

AT the monthly meeting of the Executive Committee held on the 16th inst., the accounts presented showed a decrease in the number and amount of sickness claims during the month of December. The new proposals received were above those for the same month in the preceding year, and on the whole year the numbers are about the same. The annual statement of accounts was presented and discussed and showed a satisfactory improvement in the sickness branch of the Society.

At this meeting special attention is paid to those claimants who are certified as being permanently incapacitated. This list is a long one, and the amount paid away in 1913 to these cases was over £5,000.

If ever illustration was required of the necessity for such a Society as this, and the comfort and boon it is to those who are unfortunately for ever laid aside from active duties, then these cases serve as a striking example. Many of them frankly admit that there is nothing between them, their families and the workhouse except the sickness pay they are receiving from the Society. The absence of worrying restrictions to all claimants is much appreciated, and this factor, combined with the regular weekly cheque, has much to do with the growing popularity of the Society amongst the medical and dental professions.

Society of Tropical Medicine and Hygiene.

THE Society of Tropical Medicine and Hygiene has now taken a room from the Medical Society of London, at 11 Chandos Street, Cavendish Square, London, W., for its permanent quarters. Fellows will now therefore be able to use this room, from 10 a.m. to 5 p.m. daily, both for reading and for the examination of microscopical specimens. A certain number of exchange publications lie upon the table, and the late Dr. Carnegie Brown's bequest of books forms the nucleus of a small library. These works can also be consulted.

It is hoped that Fellows upon arriving home from abroad will make use of the room and also record their home addresses there. By so doing, men from different Colonies will be able to come into touch with each other and so exchange ideas. Up to the present time the lack of such accommodation has been felt by many, and the Society hopes, now it has been able to get permanent quarters, that this want will be suitably met.

Society for Relief of Widows and Orphans of Medical Men.

AT the quarterly Court of Directors of this Society held a few days since, it was mentioned that since the last Court two of the Vice-presidents of the Society had died—Dr. Clement Godson and Mr. H. W. Kiallmark. One of the widows in receipt of grants had also died. She came on the funds in 1875 and received in grants the sum of £2,300. Her husband paid in subscriptions £37 16s. The sum of £1,260 was voted for the payment of the usual half-yearly grants to the widows and orphans, and £392 10s. was voted for special grants to be paid out of the Brickwell Fund. The invested funds of the Society now amount to £139,500.

Membership of the Society is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The annual subscription is two guineas. Special terms for life membership. Further particulars and application forms for membership may be obtained by applying to the Secretary at the offices of the Society, 11 Chandos Street, Cavendish Square, W.

University of Oxford.

AT a Congregation held on January 22nd, the following degrees were conferred—

B.M.—C. W. Wheeler-Bennett, Christ Church; R. S. A. Heathcote and W. W. Waller, New College.

University of Cambridge.

AT a Congregation held on January 23rd, the following degrees were conferred:—

M.D.—A. J. Clark, King's; A. C. D. Firth, Trinity.

M.B. and B.C.—F. S. Tinker (by proxy), Pembroke; D. S. Bryan-Brown, Downing.

B.C.—J. Deighton, Trinity; A. G. G. Thompson, Pembroke; W. Boys-Stones, Caius; J. Brewer, Emmanuel.

The following candidates have satisfied the examiners for the diploma in tropical medicine and hygiene:—

Chintaman Ramchandra Bakhlé (Major I.M.S.), Howard Crossle (captain I.M.S.), Robert Drummond, David Livingstone Graham (captain I.M.S.), and Ernest Harrison Griffin.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.

THE following candidates passed the quarterly examinations of the above Board on the 24th inst.:—

First Examination.—Robert G. Battersby, Robert Smith, Jean McM. Crawford, Lawson L. Steele, Thos. F. Kelly, Karumuri B. Swami, Arukatto P. F. Abeysuriya, Patrick A. O'Brien, George M. S. Lindsay, Janie I. McBirnie, and Norman J. Patterson. One passed in Physics, four in Biology, and 2 in Chemistry.

Second Examination.—Edward D. Kinsey, Zachariah A. Green (with distinction), William H. A. D. Sutton, John A. Tolmie, Ernest A. Hamilton, Ronald MacKinnon, Iwan Davies, Arthur Holmes, and John H. Cooper. Three passed in Anatomy and three in Physiology.

Third Examination.—George B. Charnock, John Walker, Thomas C. MacGowan, James W. Gordon, Jacobus J. de Waal, Charles C. Irvine, Elfrida H. B. Coghill, and William Walker. Five passed in Materia Medica.

Final Examination.—The following were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:—Lilian S. Wilkes, Isaac J. McDonough, Walter F. H. Pereira, Cyril Popham, Wilhelm S. Rorich, Wm. W. K. Duncan, Michael McCloskey, Wiliam C. Davis, Evan I. Parry, James Gordon-Bell, and Asutosh Sinha. Seven passed in Medicine, two in Surgery, eight in midwifery, and fourteen in Medical Jurisprudence; and George D. Cairns, M.B., Ch.B.Edin., after examinations duly passed, obtained the Diploma in Public Health granted by the above Board.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—

E. M. D. N. Baker, T. H. W. Idris, S. de Moor, J. A. Prendergast, and D. Schonken.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Pregnancy in the Rudimentary Cornu of Uterus Unicornis with Full-term Fœtus.—Quain (*Surg., Gyn. and Obs.*, xvii., 4) reports a case in a primigravida which went to full term. There were no abnormal symptoms during the pregnancy, and quickening occurred during the fifth month and continued till term, when severe pain occurred and some tissue and blood were expelled from the vagina. After this no fœtal movements were felt, and six days later there was a return of intermittent pains and the expulsion of clots. From this time there was abdominal tenderness and the size of the abdomen gradually decreased. A hard tumour developed near the umbilicus, and the breasts, which had distended with milk, decreased in size. Eight weeks after term the patient was first seen and operated upon. A tumour composed of the right rudimentary cornu was removed containing a macerated fœtus. The left tube and ovary were normal, and also the uterus. There was some connection between the tumour and the uterus a little below the fundus. The round ligament entered the tumour laterally about its middle. The fœtus would appear to have reached term, judging by the ossification of the bones, as shown by X-rays. The question is asked whether impregnation occurred by transperitoneal migration of the sperm, and this view is considered to be supported by the finding of the corpus luteum in the right ovary, but the existence of a communication between the rudimentary tube and the uterus is not excluded in the description of the case. The patient had a normal confinement fourteen months after operation. F.

Arterial Ligation, with Lymphatic Block, in the Treatment of Advanced Pelvic Cancer.—Bainbridge (*Amer. Jnl. Obs.*, lxviii., 4) says that the operation is to be advocated in all cases of advanced cancer which are no longer amenable to surgical methods. It is indicated when hæmorrhage is severe and to be feared, as by controlling the progress of the disease, the pain, fetor, and discharge may be lessened, when other methods have failed to give relief. The purpose of the operation is to diminish the blood supply to the area of cancerous involvement by the ligation of the following vessels—(*a*) internal iliacs, (*b*) ovarians, (*c*) sacra media; and to shut off the avenues of absorption by removing the lymphatic glands and vessels from the receptaculum chyli to the obturator foramen on both sides. The dissemination of the cancer may thus be checked and cachexia delayed or greatly diminished. Other complications may be corrected which tend to increase the symptoms of the disease. After the operation other adjuvant and palliative measures may be more advantageously applied. The *technique* of the operation is described fully. If cancerous adhesions are very extensive, so that it is necessary to break them up in order to reach and ligate the vessels, the operation is contra-indicated. Inflammatory adhesions may be safely dealt with. Cicatricial contractions may be cleared and the ureter freed from adhesions when it is not otherwise involved in the disease. The success of the operation depends on the occlusion of the vessels, and this is assured by ligature in two place and clamping between the ligatures. Absolute hæmostasis is important. Injury to the iliac vein is the greatest danger of the operation. F.

The Use of a Foreign Body to Prevent Adhesions.—Prime (*Surg., Gyn. and Obs.*, xvii., 5) describes the results found in a series of animals upon which experiments were made. The membrane used and recommended is a thin sheet of celloidin made by painting an etherous solution of German celloidin on glass moulds covered with a thin layer of beeswax. The celloidin must be allowed to become absolutely dry slowly, which may require several weeks at about average room temperature. It may then be pulled off and cleaned of wax in chloroform. The advantages claimed for the celloidin membrane are that it is easy to manipulate with moist hands, can be moved about after being placed, and is quite impervious to granulation tissue. It has the disadvantage that it cannot be stitched. It can be used in joints and the cranial cavity to prevent the formation of new adhesions or hinder the reformation of old ones. F.

The Treatment of Puerperal Streptococcæmia with Intravenous Injections of Magnesium Sulphate.—Harrar (*Amer. Jnl. of Obs.*, lxviii., 5) reports fourteen cases treated, and shows a mortality improved from 93 per cent. to 20 per cent. in cases in which the organism was found in the blood culture. The method employed was a slow injection into a vein of up to 400 c.c. of a 2 per cent. solution of magnesium sulphate and a similar quantity administered by hypodermoclysis, and repeated every second or third day, according to the course of the infection. There were no toxic effects, but sometimes the patient complained of a feeling of heat towards the end of the injection and of feeling faint although the pulse usually gained in quality. A little hot whisky or spirits of ammonia relieved this. The respiration may become sighing in quality, but there is no decrease in the rate or depth. The vein should not be cut down upon so that it may be used repeatedly. The following conclusions are drawn:—That the injections are perfectly harmless; they are of more value early in the course of the disease than after secondary localisation has occurred; they do not appear to be of benefit in chronic cases of secondary thrombophlebitis or pyæmia, but chiefly when the organisms are circulating in the blood. The treatment shortens the course of bacterial toxæmias in which the bacteria cannot be demonstrated in the blood by culture, and it has reduced the mortality of puerperal bacteriæmia. F.

Central Dislocation of the Head of the Femur.—Hauclex (*Med. Review*, November, 1913) reports the case of a man, æt. 60, who fell on his left side, without much force, when alighting on a platform from a train in motion. He felt no pain, but after walking a few paces lost power in his left leg. No fracture was discovered at the time. He was walking again in three weeks, and after six months climbed mountains for several hours at a time. When first seen by the writer 18 months later the left leg was much atrophied and half an inch shorter than its fellow. The pelvis followed the limb in movements of abduction, adduction and rotation, and the limb could be flexed to an angle of 70°. A hard, spherical body was palpable above Poupart's ligament within the left side of the pelvis. A skiagram now showed two-thirds of the head of the femur within the true pelvis, where a secondary capsule had formed. The great trochanter was almost in contact with the anterior inferior spine of the ilium. The rest of the pelvis was apparently intact, and the patient was fortunate in not being more crippled. Verevaux, in experiments on the cadaver, has only once succeeded in driving the head of the femur through the acetabulum into the pelvis by blows on the great trochanter. In three cases he fractured the acetabulum, and in thirteen he failed to do so. Latterly this dislocation has been successfully reduced under general anæsthesia in early cases by flexing the limb and forcibly adducting it against a wooden prop held against the inner side of the thigh to act as a pivot. Extension is then applied for six weeks and rest in bed for six more. S.

An Improvised Coin Catcher for the Œsophagus.—Gilbert (*Med. Review*, November, 1913) reports that he was called to remove a nickel coin from the œsophagus of a two-year-old child. Having no access to a suitable instrument, he devised one. He bored two small holes opposite each other about an inch from the end of a silk urethral bougie, and threaded some No. 30 brass spring wire into the hole, bringing the ends out at the open end of the bougie, and leaving a half-inch loup extending from the holes. He bent the loop into the form of a hook, and with this instrument, softened by boiling, and passed like a stomach tube, with the patient under an anæsthetic, he succeeded with comparative ease in getting out the coin. S.

Acromial Breathing as a Sign of Early Phthisis.—Magida (*New York Med. Jrn.*, December 27th, 1913) draws attention to the importance of this sign as described some time ago by Dr. Robert Abrahams. Abrahams found that in cases of early apical phthisis all the auscultatory signs are amplified, if listened to over the acromion process, while in later stages of the disease this sign disappears. An investigation of the value of this sign has lately been made at the Post-Graduate Hospital. The sign was specially looked for in 52 patients, 28 of whom were in the first stage, 14 in the second, and 10 in the third stage of pulmonary tuberculosis. The acromial breathing was found in all the patients in the first stage, in eight of those in the second, and in two of those in the third. Magida concludes that the sign is of great value in first stage cases, and since that stage is the most important from a diagnostic point of view, and as the sign is so easily elicited, it should be universally employed. It should also help towards ascertaining the advanced stages of tuberculosis, as the further advanced a case is the less probability there is of getting evidence from auscultation over the acromion process. K.

The Production of Gastric Ulcer.—Rosenow (*Jrn. of the Amer. Med. Assoc.*, November 29th, 1913) records the results of an investigation as to the production of gastric ulcer by the intravenous injection of streptococci into rabbits, dogs, and a monkey. He found that when an intravenous injection of streptococci of the proper grade of virulence was made it was often followed by an ulcer of the stomach or duodenum. The ulceration was due to a localised infection and a secondary digestion. The ulcers were usually single and deep, with a marked tendency to hæmorrhage and perforation, and resemble the human gastric ulcer in many respects. When we take into consideration this close resemblance, that injection of streptococci which have grown in tonsils produce the lesions, and that the virulence of the germs, when the affinity for the stomach is greatest, is of such a character that general infection does not occur, it appears altogether reasonable to suppose that in man gastric ulcer may be caused by streptococci. The supposed relation between infected tonsils or gums and gastric ulcer may be due, not to the swallowing of bacteria, as is usually supposed, but to the entrance into the blood of streptococci of the proper kind of virulence to produce a local infection of the wall of the stomach. Many other observations might be cited, such as associated infections of the gall-bladder and appendix, which suggest that gastric ulcer may be due to streptococci. K.

The Keeping Properties of Condensed Milks in the Tropics.—Beveridge (*R.A.M.C. Jrn.*, January, 1914), from a careful investigation of this important matter, comes to the following conclusions:—The change in colour in certain kinds of condensed milks is presumably due to brown colour being developed by reducing sugars in solution at certain temperatures, and is likely to be more marked with an increase of acidity due to bacterial fermentation; the presence of iron in the ferric state also plays a part in the production. In sterile condensed milks, chiefly found among those brands that contain no added sugar, changes are not noticeable. Sterile uncondensed tinned milk shows no change after incubation at 37° C. for many months. The increase in acidity is brought about by bacterial activity resulting from the increased temperature, and hydrolysis of the sugar follows. The bacteria concerned in the change are spore-bearing bacilli which produce an acid fermentation of the proteins. In milks containing only Gram-positive staphylococci a brown colour is not produced. It would seem that the depth of the brown colour is dependent on the amount of reducing sugar produced or of iron present, and is likely to be more intense in sweetened milks, owing to the reduction of the added cane-sugar. The increase in consistency noticed in connection with the brown coloration in sweetened milks is due also to bacillary fermentation, and some of the protein is consequently rendered insoluble. For service use in tropical climates there is no doubt that to obtain better value, and to obviate the risk of such a change occurring, especially when milks have to be stored for considerable periods, only those brands of unsweetened milk which have been proved to be sterile should be selected. K.

The Medical Profession and the Bar.

THE following members of the medical profession have been called to the Bar:—W. H. L. McCarthy, M.A., D.D.Dub., D.P.H.Oxon. (Inner Temple), R. Scott, M.B., Ch.B.Glasg., and H. C. Waldo, M.R.C.S., L.R.C.P.Lond. (Middle Temple).

The Hospital Saturday Fund.

SIR SAVILLE B. CROSSLEY presided last week at a special meeting of the Board of Delegates of the Hospital Saturday Fund Association, held at 34 Red Lion Square, when it was unanimously resolved, on the recommendation of the Distribution Committee, to award the sum of £28,400 12s. 7d. among 224 participating institutions—namely, 36 general hospitals, £8,027; 22 cottage hospitals, £520; 77 special hospitals, £10,387; 36 dispensaries, £668; 19 convalescent homes, £1,854; 23 nursing institutions, £401; and 11 miscellaneous (including ambulance, distribution, and surgical appliance committees), £6,543 12s. 7d. The grants were £4,081 less than 1912 and three fewer institutions participated. The total receipts from all sources amounted to £40,309, as compared with £45,118 in 1912.

The first meeting of the reconstituted board of delegates for 1914 will be held on February 21st, and the annual dinner will take place at the Holborn Restaurant on February 14th, when Sir T. Vezey Strong will preside.

DR. HORACE DIMOCK, M.A., M.B., B.C., of Wisbech, who died on October 27th while under remand on a charge of libel arising out of differences with local practitioners on the Insurance Act, left estate of the gross value of £3,519, of which the net personalty has been sworn at £1,831.

SIR ST. CLAIR THOMSON and Mr. Arthur Cheatle have been elected honorary members of the Società Italiana di Laringologia e Otologia.

MR. CHAS. W. M. HOPE, F.R.C.S., has been appointed Assistant Surgeon to the Throat Department of King's College Hospital.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada

TERRITORIAL CLEARING HOSPITALS.

THE titles of 14 Territorial clearing hospitals are published for the first time in the Army List of the present month, one for each division of the Force. Their headquarters are:—London (two), Aberdeen, Glasgow, Kendal, Manchester, Cardiff, Newcastle-on-Tyne, Leeds, Derby, Birmingham, Exeter, Ipswich, and Surbiton.

F.R.C.S.EDIN. (Reading).—Accidents following the production of spinal anaesthesia are very rare, but a case was reported not long ago from Germany in which acute meningitis and hæmorrhagic encephalitis followed seven hours after an operation for old prolapsus uteri, performed under spinal anæsthesia.

THE INSURANCE ACT ANNIVERSARY FESTIVAL.

Assemble, all ye panel doctors, too,
Lay down those forms and papers manifold,
Ye panel patients, leave your waiting queue,
Forget awhile your long-neglected cold,
And all ye chemists who
Sell cheaper drugs upon a special list
And your best pills withhold,
And ye insurance agents who insist
That you get nothing out of it but worry;
And all ye Foresters and Hearts of Oak
Who swear that ye are certain to be broke,
Come to the festival, make haste and hurry!
—From a "Birthday Ode to the Insurance Act" in the *Morning Post*.

M.B.GLASG. (London, N.).—We are advised that a fee of two guineas would be a suitable one to charge for the examination and report in the case to which you refer.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 28TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE (1 Wimpole Street, W.).—5 p.m.: Papers by Dr. Henry Barnes, Sir Ernest Clarke, and Dr. Chalmers and Captain Archibald R.A.M.C. (Khartoum). Mr. C. J. F. Thompson will show Specimens from the Wellcome Historical Museum.

THURSDAY, JANUARY 29TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m. Paper by Dr. S. D. Clippingdale: London as a Health Resort.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Dr. F. E. Batten: Progressive Cerebral Degeneration in an Infant, with Pathological Examinations. Dr. S. A. Kinnier Wilson: The Pathology of Pellagra.

BRITISH OTO-LARYNGOLOGICAL SOCIETY (Rooms of the Medical Society of London, Chandos Street, Cavendish Square).—4 p.m.: Exhibition of Cases and Specimens.

HARVEIAN SOCIETY OF LONDON (St. Mary's Hospital, Paddington, W.).—8.15 p.m.: Clinical meeting. A large number of clinical cases will be shown by Members of the Honorary Staff and others. Demonstration will also be given on Actinomycosis, Carcinoma of the Œsophagus and Radium Treatment, and Artificial Pneumothorax in the Treatment of Phthisis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Dockrell.

TUESDAY, FEBRUARY 3RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY: SUB-SECTION OF ORTHOPÆDICS) (1 Wimpole Street, W.).—4.30 p.m.: Mr. A. H. Tubby: Case of Operative Reduction of Dislocation of the Elbow. Mr. Paul P. Roth: Case of Injury to Upper Epiphysis of Left Femur, with Scoliosis.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE) (1 Wimpole Street, W.).—5 p.m.: Adjourned Discussion on Vaccines from the Standpoint of the Physician, opened by Dr. H. D. Rolleston.

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Laboratory meeting: Pathological Department, University College Hospital Medical School.

RÖNTGEN SOCIETY.—8.15 p.m.: Meeting at the London Hospital. Dr. Gilbert Scott will conduct visitors over the X-Ray and Electro-Therapeutic Departments of the Hospital and give a demonstration of the Wilson Portable Coil Apparatus, and will show a number of interesting plates.

THURSDAY, FEBRUARY 5TH

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's General Hospital, Tottenham).—4.15 p.m.: Clinical meeting.

Appointments.

HODGSON, JOHN FREDERICK, M.D., Ch.B. Vict., D.P.H., Honorary Medical Officer to the Royal Halifax Infirmary.

MENCE, WILLIAM CHARLES, L.R.C.P.Lond., M.R.C.S., Medical Officer of Health of Chard, Somerset.

PICKLES, C. C., M.R.C.S.Eng., L.R.C.P.Lond., D.P.H.Leeds, Medical Officer to the Gateforth Sanatorium, Leeds Tuberculosis Association.

STARK, J., L.R.C.P. & S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Kirkliston District of the County of Linlithgow.

TAYLOR, A. L., M.B., B.Sc.Edin., M.R.C.P.Edin., Senior Assistant Medical Officer at the Govan District Asylum.

THOMPSON, CHARLES J., B.Se.Birm., L.M.S.S.A.Lond., Clinical Assistant to the Royal Orthopædic and Spinal Hospital, Birmingham.

Vacancies.

Newcastle-upon-Tyne City Asylum, Gosforth, Newcastle-upon-Tyne.—Junior Assistant Medical Officer: Salary £200 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent.

Southwark Union, London.—Third Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to Sidney Wood, Clerk, Union Offices, Ufford Street, Blackfriars, S.E.

Royal Albert Edward Infirmary and Dispensary, Wigan.—Senior House Surgeon. Salary £120 per annum, with board, apartments, and washing. Applications to Will Taberner, General Superintendent and Secretary.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Leasowe Sanatorium (Hospital for Surgical Tuberculosis in Children).—Resident Medical Officer. Salary £250 a year, with board and residence. Applications to the Chairman of the Leasowe Sanatorium Committee, 62 Seel Street, Liverpool.

Dorset County Hospital, Dorchester.—House Surgeon. Salary £100 per annum, with residence, board, and laundry. Applications to W. E. Groves, Valetta, Icenway, Dorchester.

Lancashire County Asylum.—Assistant Medical Officer. Salary commencing at £250, second year £300, with board, residence, and washing. Candidates must be unmarried and under 30 years. Applications to the Medical Superintendent, Whittingham, Preston. (See advert.)

National Maternity Hospital, Dublin.—Assistant Master. Salary at the rate of £50 per annum. Applications to the Secretary. (See advert.)

Births.

DICK.—On January 24th, at Roxeth, The Glebe, Blackheath, the wife of F. A. Dick, M.B., Bac.Surg., of a daughter.

GAUVAIN.—On January 24th, at 57 Beaumont Street, W., the wife of H. J. Gauvin, M.A., B.C.Cantab., of 130 Harley Street, W., and Alton, Hants, of a daughter.

HIGGS.—On January 21st, at 40 Palace Mansions, Kensington, the wife of Frederick W. Higgs, M.D., of a daughter.

KING.—On Friday, January 23rd, at Peckham House, Peckham, S.E., the wife of Frank R. King, B.A.Cantab., M.R.C.S., L.R.C.P., of a daughter.

MAIDLOW.—On January 18th, at the Ridge, Ilminster, the wife of William H. Maidlow, M.D.—a daughter.

MANBY.—On January 25th, at 121 Victoria Street, Westminster, to Dr. and Mrs. E. P. Manby,—a son.

Marriages.

LEES—BOMFORD.—On January 22nd, at the Baptist Chapel, Atch Lench, Allan Henry Lees, M.A., of Long Ashton, Bristol, youngest son of Dr. David B. Lees, M.D., F.R.C.P., and Mrs. Lees, 22 Weymouth Street, Portland Place, W., to Mary Hughes, sixth daughter of Mr. and Mrs. G. F. Bomford, Manor House, Atch Lench, Evesham.

WOOD—KEIR.—On January 20th, at St. Marylebone Presbyterian Church, W., Stanley Wood, M.R.C.S., L.R.C.P., of 22 Accrington Road, Burnley, to Mary Robb Keir, of Lauriestón, Falkirk.

Deaths.

EVANS.—On January 18th, at Elmfield, Crediton, Evan Evans, Esq., M.R.C.S., L.S.A., aged 74 years.

JOHNSTONE.—On January 24th, suddenly, at 10 Southwick Street, Hyde Park, Dr. James Pierce Johnstone, of Annandale, Langport, Somerset, aged 55 years, son of the late John Maxwell Johnstone, M.D., Medical Officer of Health, Georgetown, Demerara.

SHEPHERD.—On January 16th, at 9 Ogle Terrace, South Shields, Harry Fergusson Shepherd, L.R.C.P. and S.Edin, L.F.P.S. Glasg., aged 38.

TURNER.—On January 17th, at Park Lodge, Buxton, Frederick Turner, M.R.C.S., L.R.C.P., formerly Medical Officer of Health for Buxton, aged 70.

WHITCOMBE.—On January 24th, at Gravesend, Philip Whitcombe, M.R.C.S., last surviving son of the late Edmund Whitcombe, of Cleobury Mortimer, in is 98th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, FEBRUARY 4, 1914. No. 5.

NOTES AND COMMENTS.

Unqualified Persons and Insurance Medical Benefits.

THE regulations for medical benefit under the National Health Insurance Act, dated January 10th, 1914, contain a new clause (Regulation 44, 2) the effect of which will be certain to arouse the feelings of the medical profession all over the country. The clause reads as follows:—"Where the insured person contracts with a person other than a duly qualified medical practitioner to obtain treatment (whether including drugs and appliances or not) from him for a fixed sum for the year or any part thereof, the Committee may make such contribution towards the sum contracted to be paid not exceeding in amount the maximum contribution payable in the case of a person who contracts with a duly qualified medical practitioner as they think fit, but upon any representation being made by a society that the treatment is not such as will adequately protect the funds of the society, the Committee may either withhold the contribution or make such a deduction therefrom as they may in any case determine." If we interpret it aright it can only mean that unqualified persons of any sort, including bonesetters, magnetic healers, herbalists, Christian Scientists, faith-healers, "Peculiar People," and every possible variety of amateur practitioner, may be placed on exactly the same footing as those duly qualified and registered under the Medical Acts.

Strange Bedfellows.

IF asked to administer the Act along with herbalists and other unqualified persons, it is more than probable the majority of panel doctors would instantly resign. We doubt if any Government would have the temerity to run dead against the whole scheme of qualified medical practice embodied in the Medical Acts! Either legal medical qualification is a sham and herbalism a true science or the other way about. If herbalists and other unqualified persons are at liberty to practise medicine under the National Insurance Act, they must logically have the same licence under any other Act. It is inconceivable that the framers of the new clause had any intention of nullifying the whole spirit of the Medical Acts, yet it is difficult to place any other construction upon it. The attention of the General Medical Council, and all the councils of our leading Medical Societies, great and small, may well be directed to a consideration of the matter, with a view to bringing pressure to bear upon the Government for the speedy withdrawal of the clause. In our news column it will be seen that the council of one of the newest medical organisations, the National Medical Union, has already lifted up its voice in protest against the latest anomaly of medical legislation.

St. George's Hospital.

THE resignation of the Princess Christian from the Presidency of St. George's Hospital has naturally opened the door to surmise. Following as it did the refusal to allow Her Royal Highness to conduct a private investigation into the facts connected with recent official appointments, it is reasonable to suppose that the withdrawal of the Royal patronage arose out of the non-compliance of the executive with the request. At the same time it seems clear enough that the hospital executive is really within its legal and moral rights in retaining the management of its own affairs in its own hands. Mr. A. William West, the gentleman who resigned the honorary treasurership of the hospital in order to hold a combined post as paid treasurer and secretary, is the son of the Right Hon. Sir Algernon West. It is impossible to believe that social influences could have been brought to bear so profoundly on the internal life of a great London Hospital as to demolish and create important posts for the benefit of any single individual, let alone a member of the executive. The governors of St. George's, anyway, would have nothing to do with the proposed changes. Mr. West appears to be still a member of the executive, for we understand he was chairman of the subcommittee that asked Princess Christian to reconsider her decision in the interests of the hospital. It is deplorable that a Royal President should have become involved in what appears to have been a somewhat complicated domestic tangle.

Anæsthetic Burns.

EVERYONE who has administered an anæsthetic knows how frequently the vapour will produce a little temporary erythema upon the face. In the case of chloroform or ether given by the open method, a few drops of the anæsthetic are apt to trickle down the mask or holder and produce a similar rubefacient effect which, if at all intense, goes by the name of an "anæsthetic burn." Fortunately such lesions are rarely serious, though the circum-oral erythema may be somewhat alarming. A case was heard last week before Mr. Justice Lush, in which an infant scholar in one of the London County Council's elementary schools made a claim for damages for personal injury from the alleged negligent administration of an anæsthetic. The familiar A.C.E. mixture was used in the case, and the operation was one for the removal of adenoids and tonsils. Afterwards the child was brought back to the medical treatment centre with its lips blistered and burns upon the cheek. Evidence was given to the effect that the child had struggled a good deal during the administration, and that a certain degree of redness

subsequent to the operation was no evidence of negligence. A verdict was returned for the defendants with costs, which is only what might have been expected, seeing that such slight accidents are unavoidable in a certain percentage of cases.

X-Rays in Diagnosis.

THERE can be little doubt that in all cases of obscure injury to bones or joints it is much safer to take a skiagraph of the lesion, or more than one, if necessary, in order to supplement the evidences of the special senses of sight and touch. Failure to do this may land the practitioner in an awkward predicament and lay him open to a possible charge of malpraxis. A case of the kind was tried last week before Mr. Justice Scrutton, in which a woman claimed damages from a medical man for the alleged negligent treatment of an injury to her knee. Every surgeon knows the difficulty of distinguishing between a ruptured ligament in the neighbourhood of the patella and a partial fracture of the bone itself, and an X-ray photograph would be necessary for the complete elucidation of the case. The evidence was that the medical man had suggested the advisability of a radiograph being taken, but that the patient demurred on the ground of expense. The injury was treated as a torn ligament with bandaging and rest, but a skiagraph was ultimately taken, which revealed a partial fracture of the patella. Expert evidence was given in support of the defendant's treatment, which was stated to be the correct one, even if the X-ray photograph had been taken earlier. A verdict was returned in favour of the medical man with costs, saying that there was no negligence but an error of judgment. Now that we possess the power of actually seeing the position of bones and other opaque objects upon a sensitised screen, or of studying their relationships in a finished print, any practitioner who dispenses with the assistance thus afforded does so at his own risk.

Paregoric and Laudanum for a Baby.

THE deadliness of narcotic drugs to infants is well known to medical men. In the case of various soothing syrups and cordials, and the like patent medicines sold for babies, laudanum and its derivatives often form the chief active constituent, and there can be little reasonable doubt that a heavy death-toll results from their use. In all the grim tragedy of the quack medicine traffic there is none more reckless and criminal than that which gives Government sanction to the sale of deadly poisons under the guise of infant remedies. What has the Select Committee on proprietary medicines to say on the point? Or has that august body wearied of its researches into the wilderness of chicanery already revealed to its gaze? A certain inquest held at Hackney early in December last may be commended to its notice. A medical man living in Homerton, Dr. William Duncan, declined to grant a medical certificate of death in the case of a child, seven years of age. His refusal was based mainly on the ground that he was not called in until the day before the death, but he also found that the medicine he ordered was not properly administered. The coroner remarked that it amounted to this, "that the doctor refused the certificate as a protest against the failure of the parents to call in a doctor earlier." That view was endorsed by the verdict and rider of the jury. Another serious feature of the case was the home-made medicine with which the mother, an Italian, had dosed the unfortunate child. It was stated in evidence that the mixture thus administered was made up of Irish moss, black treacle, peppermint, laudanum, and paregoric. It would be difficult to conceive a more deadly potion for a child of seven years suffering from bronchitis.

Where is the Children Act?

HERE is a case of neglect on the part of parents to provide proper medical attention for a child that falls under the Children Act. If the Hackney Coroner is cognisant of the provisions of that salutary Act, it was surely his duty to draw the attention of the jury to the point. It would be nothing short of a national calamity were so important a measure of social reform to become a dead letter. On previous occasions we have referred to the fact that coroners as a class have it in their power materially to advance the administration of the Children Act. In the Hackney case it seems not unlikely that the parents might be prosecuted under the Act. As a matter of fact, the only protest against the circumstances of the child's death came from the medical attendant, who discharged an unpleasant duty where apparently the whole forces of administrative and legislative law failed to intervene. It is to be hoped that the progress of social evolution will one day furnish the community with an efficient executive as well as sound laws. The Children Act is admirable in principles, in intention, and in its provisions, but for all that it is to a great extent a dead letter. So far as patent medicines are concerned we have pointed out that the Act in question furnishes coroners with a potent weapon against quackery in cases where it can be shown that parents or guardians have administered such preparations to children in place of obtaining qualified medical advice.

LEADING ARTICLES.

THE IRISH MEDICAL ASSOCIATION AND THE "MEDICAL PRESS AND CIRCULAR."

WE are able this week to make an announcement which will, we think, prove of great interest to our Irish readers, and to the Irish medical profession generally. At its last meeting the Council of the Irish Medical Association, having considered terms offered by us, directed the Committee of Council to make arrangements with the MEDICAL PRESS AND CIRCULAR by which its IRISH SUPPLEMENT will become the official organ of the Irish Medical Association. It may be well to recall the special circumstances which render this arrangement specially important at the present juncture. The recent increase of the subscription of the British Medical Association has given rise to certain important questions for the profession in Ireland. It is felt that in the past the Association, whose might lies on the eastern side of the Channel, has done little, if anything, for Irish professional interests. Its *Journal* has, on more occasions than one, exhibited what—in Ireland, at any rate—is regarded as an anti-Irish bias. The necessity which has called for the increase of subscription—if, indeed, it be a necessity—is entirely British. Insurance Act problems in Ireland are different from those in the other parts of the kingdom, and it is for a struggle which does not involve Irish medical interests that the Association demands funds. It was obvious that, under these circumstances, a large number of members resident in Ireland were likely to withdraw from the British Medical Association, and, as a matter of

fact, many resignations have been sent in. The opportunity has, therefore, occurred for the Irish Medical Association to consider whether it could take any steps to attract any of the unattached members of the profession to its ranks. The British Medical Association had, as we understand, some nine hundred or a thousand members resident in Ireland, while the Irish Medical Association has some six hundred. This is but a small proportion of the total number of medical men in the country —some two thousand seven hundred. Now that the Irish Medical Association is in a position to offer not merely the advantages of belonging to the representative medical organisation of Ireland, which is a Medical Defence Union to boot, but the regular receipt of a leading weekly medical journal, we see no reason why it should not speedily double or treble its membership. The exact terms we have been enabled to offer to the Association may be seen by members of the Association in the current number of their *Journal* (p. 21). It is not necessary here to enter into these business matters in detail. It is sufficient to say that the terms are such as permitted the Council to accept them without any increase of the present subscription to the Association. The Irish Supplement will appear fortnightly, as hitherto, and will henceforth be the official organ of the Association. If special occasion demands, it will be increased in size. In addition to the Supplement fortnightly, each member will receive the Medical Press and Circular weekly without additional charge. There will be no further liability on the Association than the payment of the *per caput* rate agreed on. We find it necessary to state this definitely, as the *Journal of the Irish Medical Association*, in its leading editorial, makes the extraordinary statement that the Association have to "pay for the editing of the Supplement." With the rest of this astonishing editorial we prefer not to deal, beyond remarking on the anomaly of the leading article being directed to an attack on the policy of the Council, whose servant the editor is. The advantages to the Association and the profession in Ireland from the arrangement which has been come to must be obvious to all. The Association will have as its organ a journal which, as a result of its long and honourable life, carries in Ireland a might no other journal can equal. The Medical Press was founded in the interests of the Irish medical profession, it was for many years the organ of the Irish Medical Association, and though in recent years its sphere of influence has spread beyond the four seas of Erin, it has always regarded the maintenance of the interests of the Irish profession as one of the chief reasons of its existence. By its help, as we sincerely believe, the Irish Medical Association can become so strong as the representative professional organisation that no one can venture to question its authority.

THE VOLUNTARY HOSPITAL SYSTEM.

As a progressive profession medicine plays an important part in advancing the general welfare of mankind. Within the last few generations its conquests have been innumerable, and have been gained in the realm of practical administration as well as in that of scientific advice. Rapid progress of this kind, however, demands frequent revision of our methods as a profession and of our relation to the outside community. Recently politicians have reminded us sharply that in their modern conception of the proper functions of a State the services of a highly-skilled and liberal profession may be more or less commandeered in the interests of the community. Medical men protested stoutly against this trespass on what they had hitherto regarded as their private and personal rights, but for all that they were compelled to surrender. The panel system thus established—whatever its defects—has undoubtedly constituted a solid advance in the co-ordination of the public medical work of the nation. Already the responsibility of the State in that direction has been recognised in the poor law, in medical quarantine, in the school medical service, and, last of all, in the National Insurance Act. Who can wonder that these measures have suggested a further extension in the shape of a national medical service? So rapid has been the development of politico-medical movements in recent years that the medical profession will do well to ponder this matter now while there still remains time and opportunity to do so. One of the chief features of the situation is the position of the voluntary medical charites. Can it be said that under present conditions the hospitals discharge adequately, and to the best advantage, the responsible duties they have assumed in relation to the public? The answer to that question raises the whole subject of hospital reform, which has been clamoured for by the general body of the medical profession for several generations. Can it be said that any single grievance has been removed or any defect or abuse remedied? First of all, it must be conceded that the voluntary hospital system of the United Kingdom is hopelessly inadequate to meet the requirements of what may be conveniently termed the "hospital class." That deficiency is to a great extent due to the waste of the out-patient departments, which spend huge sums in dealing with trivial ailments, to the loss and detriment of outside medical practitioners. Has any effectual step been taken to curtail this unjustifiable waste and competition? It has been pointed out that the expenditure of different hospitals varies within wide limits as to the prices paid for commodities—has any real step been taken towards the businesslike common system of purchase in the most favourable markets? Then, as to the staff medical appointments, has anything been done to check pluralities or to standardise the amount of work that can be reasonably expected from any one man? At the present moment the holder of a staff appointment has to deal with a number of patients so great as to render it hopeless to give them proper care and attention. If the hospital service of the United Kingdom is to do justice to its patients, there can be little doubt that there must be a considerable increase of staff appointments. The present position is tragic. After years of special training and service in junior posts, a medical man who has secured a post on the staff of an important hospital is compelled to face the drudgery of the out-patient room—it may be for ten or even twenty years—before he secures promotion to a higher post which confers on him the privilege of obtaining beds in the hospital wards. If there are, say, one hundred patients in the out-patient department, why should they not be divided amongst three or four members of the staff? This inadequacy of staff is a crying evil in modern hospital life, and there appears to be little prospect of its being dealt with short of the compulsion of State pressure. Then, again, there is the unjust rule that demands the higher medical qualification of certain privileged medical corporations as a condition of staff appointments. Under that antiquated provision the holders of Scotch and Irish medical qualifications, and of not a few English Universities, are excluded from the chief London and many provincial hospital appointments. Under a State system that invidious privilege would certainly disappear. It would be

easy to enlarge upon the defects of the voluntary hospital system in the United Kingdom, but enough has been said for the present purpose, which is to suggest that it would be well to consider, and, so far as might be feasible, to anticipate the inevitable changes that must sooner or later supervene by a wise and timely setting of the house in order. It will be of little use to attempt to stay the hands of the State at the eleventh hour, and to protest against reforms that should long since have come from within the walls of our great charitable institutions.

CURRENT TOPICS.

A Birthmark for Tinned Foods.

A PURE food supply is clearly a cornerstone of the foundation of public health, and around the problem of its safeguarding have raged many battles royal between the man of commerce and the sanitarian. Numberless have been the alarms, skirmishes and pitched fights over what the Americans call "canned goods." The food supply of the United Kingdom being largely drawn from distant parts of the globe, the packing of perishable food in hermetically-sealed tins has been a source of wealth to its commerce and of convenience and value to its inhabitants. Unhappily, experience has shown that tinned food is not without its peculiar dangers, not the least of which develop as the result of age. Not long ago the Public Health Committee of Stepney Borough, having deeply pondered over the problem of this class of foods, suggested that the year in which the goods were canned should be marked on the tin. Why not? In the case of eggs, several private firms have adopted the plan of stamping the date of birth—so to speak—on the egg. It is of infinitely more public importance that tinned tomatoes, salmon, corned beef, and so on, should be protected in that way. The Stepney Committee have handed in their eminently sane and practical recommendation to the Local Government Board. It is to be hoped that Mr. John Burns will rescue this little public health safeguard from burial in the dusty pigeonholes of Whitehall.

The Keeping Properties of Condensed Milk.

THE brownish tint observed upon opening certain brands of condensed milk, after being kept for some time in a hot climate, has frequently been commented upon, but because there is no obvious alteration in the taste, the change has not been regarded as detrimental to health. An investigation into the subject has recently been undertaken by Lieut.-Colonel W. W. O. Beveridge, D.S.O., R.A.M.C. (*a*), who has found that an increase in the acidity of the milk before heating, or the presence of iron in the ferric state, or of added sugar, or both, are capable of producing the change to a brown colour when exposed to a temperature of 100° C. for one hour. In sterile condensed milks which contain no added sugar colour changes are not observed. The increase in acidity, which is an important factor, results from bacterial activity, which becomes operative at the high temperatures of tropical climates. The bacteria concerned in the change are spore-bearing bacilli which produce an acid fermentation of the proteins. The depth of the colour seems to be dependent upon the amount of reducing sugar or iron present, and is likely to be more intense in tion there is also noticed an increased consistency, sweetened brands. Along with the brown coloradue likewise to bacillary fermentation, and some of the protein is rendered thereby insoluble. As a result of these researches it is suggested that for Service use in tropical climates only those brands of unsweetened milk known to be sterile should be selected.

Life in an "Igloo."

ELSEWHERE in our columns will be found an account of the interesting lecture delivered by Surgeon Murray Levick last week, at the Royal Society of Medicine, on "The Experience of Captain Scott's Northern Party from a Medical Point of View." The effect upon the system of intense cold in modifying the processes of metabolism is shown by the fact that the party were able to subsist for seven months in an "igloo," or ice cave, built out of a hard snowdrift, upon a carnivorous diet without contracting scurvy. Frequently the seal meat was frozen so hard that portions of it had to be broken off with a chisel and hammer. One troublesome result of continued subsistence upon flesh food was the occurrence of uricacidæmia, with its attendant painful urinary phenomena. The experiences of the party in breathing vitiated air for a long period are noteworthy as showing how tolerant the respiratory centre can become to life in an ill-ventilated space provided the temperature be low. After five months, however, of these conditions, the party wisely determined to leave the "igloo," and fortunately, after three weeks' marching, they had a lucky find in the shape of a hut containing an abundant supply of lard, biscuits, and chocolates, which they devoured ravenously. Strange to say none of them suffered from dyspepsia. In spite of all the dangers and hardships encountered by the Northern Party, it is a matter for congratulation that the health of the members suffered comparatively little under such trying conditions.

Recent Light on Pellagra.

FEW diseases have excited so much interest among the profession during recent years from the ætiological standpoint as pellagra. When it was announced that several cases of the disease had actually occurred in the British Isles, several of them being inmates of asylums, neurologists and dermatologists were at once on the alert lest they should overlook cases under their care. In our clinical lecture this week, by Dr. Charles R. Box, a comprehensive account of pellagra is given from the clinical aspect as it has been observed in Great Britain. As far as the cases in this country are concerned, it is pointed out that the cutaneous manifestations are quite characteristic, and that they constitute the first reliable clue as to the nature of the malady itself. The mental symptoms, on the other hand, appear to have no diagnostic qualities, and they are very variable as to their time and mode of onset. According to the summary of the First Progress Report of the Thompson-McFadden Pellagra Commission for the Investigation of Pellagra in the United States, recently published in the *Journal of the American Medical Association*, the conception that pellagra is an infectious disease transmissible from person to person in some unknown manner is strongly supported by many of the field observations. The present report further states that no evidence has been discovered by the Commission incriminating flies of the genus *Simulium* (buffalo gnats) in the causation of the disease except their universal distribution through-

out the area studied. It is suggested that the *Stomoxys calcitrans* (stable fly) is a likely carrier of the infection. The theory that pellagra is closely connected with poor state of nutrition lends some support to its classification among the so-called deficiency diseases. Much more research is needed, however, before any definite pronouncement can be made as to the ætiology of this perplexing malady.

Excelsior.

Little things are often significant. Petty details of the daily round seem connected in some queer fashion into principles. Man has been said to be born to trouble as the sparks fly upward. The simile is not a good one. Sparks certainly fly upward, but they do not conjure up a picture of an hourly-harassed humanity. Rather the reverse. Things that go up are pleasant. Many of the influences that comfort us are optical. The changing flames of a fire, only tied to earth by their teeming origin, have an effect that no radiator made by man could ever suggest. A blind man does not smoke, and a seeing one gets little pleasure from his pipe in darkness. We are fascinated by a balloon. Ascension affects us. A steady, rhythmic rise has an almost hypnotic value. It may be because it is unusual. The attraction of the centre of the earth exhibits itself so often that we always expect it. Matter is falling about us as thick as thieves in Vallombrosa. We do not notice it. But the scarcity of levitation draws our attention, mesmerically strokes our retina, and induces an unrivalled sense of well-being. We are of the earth, and wings will be always wonderful. The difficult thing is the good thing—any fool can get down to Avernus. We place our gods above our heads, and no good thing can come out of the earth whose surface is our own. The reiteration that has damned the form of "Excelsior" shows the universality of its sentiment. We know that we are groundlings and happy prisoners of hope. But there are worse things than a divine discontent.

London as a Health Resort.

In spite of all its fog and grime, Londoners have the proud assurance of knowing that their city is the healthiest in the world. Even in ancient times it had this reputation, and one cannot take up a book upon old London without finding a reference to some such favoured spot as Clerkenwell, Kingsland or Canonbury, among the inner ring of suburbs, as being a health resort suitable for the restoration of shattered nerves, or what not. In an interesting paper read, last week, before the Section of Balneology and Climatology of the Royal Society of Medicine, by Dr. S. D. Clippingdale, it was pointed out that the Metropolis owes its healthiness largely to its situation and its soil. Receiving air straight from the North Pole, and lying on an inverted basin of clay, the natural advantages of London are greatly enhanced by its large number of open spaces. The County Council alone control 103 such spaces, having an acreage of 5,000, which compares favourably with the 540 acres of Paris and the 1,222 acres of Berlin for a corresponding area, and this does not include the Royal Parks and private squares. The Metropolis has had its share of epidemics, but its mortality rate in the Black Plague was rather below the average. Its endemic disease, "London ague," a malarial affection, has practically disappeared. As regards its climate, there is nothing to boast of or defend. Its average rainfall is 22 in., as compared with 34 in. for the whole country, but the high daily variations of temperature render it unsuitable for those suffering from lung affections. Bronchitis, asthma and whooping-cough, however, are said to be relieved by the London streets, as also is hay fever. For cases that require the very opposite of a rest cure London is unrivalled.

PERSONAL.

Dr. H. E. P. Castellain, M.A.Oxon., B.C.Cantab., has been appointed Medical Registrar to St. Mary's Hospital.

Dr. Ernest Littleton Sandiland, M.B., B.S. Lond., D.P.H., has been appointed Tuberculosis Officer for the County of Herefordshire.

Dr. J. Dundas Grant, Consulting Surgeon to the Central London Throat and Ear Hospital, has been made an Honorary Member of the Laryngological Society of Berlin.

It is announced that the complimentary dinner to Dr. Christopher Addison, M.P., has been unavoidably postponed until Friday, February 6th, at the Hotel Metropole, at 7.30 p.m.

Dr. F. Douglas Turner, M.B.Lond., has been appointed Medical Superintendent of the Royal Eastern Counties Institution for Imbeciles and the Feeble-Minded, Colchester.

Dr. John Shepley-Part, M.D.Brux., M.R.C.S., L.R.C.P.Lond., L.S.A., has been appointed Radiographer to the Mount Vernon Hospital for Consumption and Diseases of the Chest.

Dr. Frederick Taylor, M.D., F.R.C.P., has been elected chairman of the Committee of the Medical Members of the Senate of the University of London for the remainder of the year 1913-14.

Brevet-Col. H. F. Cleveland, I.M.S., Assistant Director of Medical Services to the Aden Brigade, has been appointed Honorary Surgeon to the Viceroy and Governor-General of the East Indies.

Dr. Josiah Oldfield will give a course of eight lectures on dietetics at the Royal Institute of Public Health, Russell Square, W.C., on Wednesdays, at 4.30 p.m., commencing February 4th (to-day).

Dr. Ivor Jones Davies, M.D., M.R.C.P.Lond., and Dr. Herbert Thomas Evans, M.A., M.B., B.Ch.Oxon., M.B., B.S.Lond., have been appointed Assistant Physicians to the King Edward VII.'s Hospital, Cardiff.

A sum of money, sufficient to bring in about £300 a year, has been left to the medical school of Guy's Hospital, under the will of the late Mr. J. H. Targett, Obstetric Surgeon to the hospital, for the benefit of the new pathological department.

Dr. Edward Walford, Medical Officer of Health for the City and Port of Cardiff, was the recipient the other day of a handsome silver centrepiece from the officials of the Corporation and others as a token of their high esteem and personal regard upon the completion by him of 25 years' service under the Corporation as Medical Officer.

At a recent meeting of the general council of the Institute of Hygiene the following were among those elected as Honorary Fellows of the institute:—Sir Ronald Ross, Sir James Mackenzie Davidson, Dr. Arthur Newsholme, C.B., Sir Malcolm Morris, Sir E. A. Schafer, Sir Oliver Lodge, Sir William Leishman, Sir Arthur Whitelegge, and Professor Matthew Hay.

CLINICAL LECTURE

ON

PELLAGRA AS IT HAS APPEARED IN GREAT BRITAIN. (a)

By CHARLES R. BOX, M.D.Lond., F.R.C.P., F.R.C.S.,

Physician with Charge of Out-patients at St. Thomas's Hospital, Physician to the London Fever Hospital.

PELLAGRA is a disease the duration of which, in acute cases, may sometimes be reckoned only by months, but which more commonly runs a protracted course which is measured by years.

Clinically it is often described in stages, but the demarcation of these, as might be expected, is not clear cut, and the tendency among recent observers is to regard them as very artificial. It is alleged, with reason, that the disease progresses by general exacerbations rather than by stadia, so it is preferable to adopt a classification of the symptoms which is based on the systems affected than to divide the disease into periods of neurasthenia, dermatitis and gastro-intestinal disturbance, nervous manifestations, and terminal cachexia.

The manifestations of pellagra are trimorphic in that they affect the alimentary, the cutaneous and the nervous systems. It appears that the pathological changes pick out the ectodermal and entodermal in preference to the mesodermal structures. Sometimes the stress falls more particularly on one and sometimes on another of the systems mentioned.

ALIMENTARY SYMPTOMS.

The common alimentary symptoms are vague abdominal discomfort, heartburn, nausea, diarrhœa, rarely constipation. Vomiting is present in some cases, anorexia and refusal of food in others. The most constant symptom of all is the looseness of the bowels. The motions are numerous and offensive; they at times may contain mucus and blood. The hæmorrhage has been known to be profuse. Incontinence of fæces may occur and rectal prolapse has been noted.

These symptoms are not in themselves distinctive; a more suggestive event is their association with a severe and painful stomatitis which is accompanied by rawness and ulceration of the buccal mucous membrane, salivation, and sometimes a parotitis on one or both sides.

The tongue, which may be coated at first, soon peels, and may appear raw and red; the rawness may be limited to its edges. The fauces may be swollen, and burning sensations accompany the act of swallowing. Reflex spasm may render deglutition impossible. A salty taste is sometimes experienced.

The intestinal disturbance may be accompanied by abdominal tenderness, either general, or localised in the lower part of the abdomen. This localised tenderness, accompanied by the signs of toxæmia, has already led to operation on the appendix.

In the presence of severe alimentary symptoms the loss of flesh and strength is very rapid. With their subsidence the weight may be regained with equal rapidity.

The urine has contained albumen in some instances, and indoxyl also may be found, its presence being attributed to intestinal toxæmia. In severe and fatal cases a definite nephritis may occur.

THE PELLAGROUS DERMATITIS.

The cutaneous manifestations of pellagra are in themselves distinctive. The British cases in their skin symptoms correspond with those described on the Continent and in America. Judging from what has occurred in this country, the opinion expressed by Merk that the cutaneous symptoms of pellagra possess the same diagnostic value as do the rashes of scarlet fever, measles, variola, and varicella is not far from the truth. The dermatitis, indeed, in nearly every case, has afforded the first reliable clue to the nature of the vague digestive, nervous and psychical symptoms which occur in the disease.

The most striking points about the eruption are its seasonal incidence, its appearance on uncovered parts, its symmetry, its sharp delimitation, and the frequency with which it has been described as sunburn. It is not invariably present—or, at all events, noticed—with the earliest manifestations of the disease.

The rash appears in the spring or early summer and disappears as autumn advances. It tends to recur at about the same period in succeeding seasons, but its reappearance in consecutive years is not invariable.

It is practically limited to those parts which are exposed to the action of sunlight, and exacerbations may be induced by fresh exposure. The typical distribution is on the backs of the hands and forearms, the face, the nape of the neck, and the chest, if uncovered.

On the hands the skin of the ungual phalanges may escape. In the region of the wrist the front, as well as the back, may be invaded, the front usually in a V-shaped form from the radial side. The palms of the hands almost invariably escape, but slight desquamation has been observed along the creases. On the forearms the dermatitis is, as a rule, limited to the lower part of the extensor surfaces, terminating by a horizontal line a few fingers' breadth above the wrists. In some cases it has reached higher than this, and it is also apt to show itself about the bony points of the elbows, perhaps being induced by pressure or friction in this situation.

The rash on the face in its most typical form assumes the shape of a butterfly patch, crossing the bridge of the nose and implicating the malar regions. The rule that the eyelids escape is not without exceptions. The dermatitis may also occur about the muco-cutaneous junctions of the nostrils and lips and implicate the chin.

Invasions of the nape of the neck, the rash extending upwards behind the ears, and an imperfect attempt at the pellagrous necklet, have also been seen. The ankles do not appear to have been involved in the British cases, these parts not being exposed as a rule; but in one case the dorsa of the feet were attacked. An erythema sometimes appears around the anus, in the perinæum, and on the scrotum. Quite a severe dermatitis may appear about the vulva and involve the vagina.

I have only one account of what appeared to be a *generalised* pellagrous dermatitis, and this case proved fatal in the desquamation period, with grave nervous symptoms and glycosuria.

(a) Read before the North-East London Clinical Society, January 8th, 1914.

In its earliest stage the eruption may appear in the form of rosy macules, which by their fusion cause the sites of election to appear red and puffy as though sunburnt. Slight sensations of burning and soreness are at times complained of. In some cases bullæ appear on the inflamed parts. In a week or two the inflammation becomes less intense and the colour less bright. A branny desquamation ensues; but, even whilst this is in evidence at the central parts, a well-defined marginal redness may be seen. The affected skin may show slight fissures or become the site of secondary pyogenic infections. The dermatitis matures much more rapidly than it subsides; it may be awakened to fresh activity by injudicious exposure to the direct rays of the sun. It generally remains in evidence until the summer ends.

During regression the rosy colour fades, and the surface may show a brownish or yellowish tint. I have seen that form of pigmentation which has been compared to the colour of sepia or staining with walnut juice. Hyperkeratosis may be a marked feature, and in some cases the skin has been likened to hide or parchment.

The bullous form of dermatitis, known as wet pellagra, is usually accompanied by very severe alimentary and nervous symptoms. In this form blisters have been described which resembled those of a severe scald. When the cuticle separates, a raw surface is left. A raw surface may also be produced by the shedding of undermined or thickened skin.

The completeness with which the dermatitis may disappear at the end of the pellagra season is very characteristic. On examining the hands after subsidence of the rash the clean, pale, smooth appearance of the skin is often very striking; but, even when the hands are free from dermatitis, the regions of the wrists may still show a rough and chafed appearance.

The finger nails usually escape, but a dry, lustreless appearance of the hair has been noted.

I have not seen nor have I found in the accounts of indigenous case any note of the subcutaneous hæmorrhages in the inflamed areas which have been described abroad, and which possibly led some authors to the suspicion that there was a scorbutic element in the disease.

The areas of dermatitis are distinguished by their symmetry and their abrupt margins. Of course, wherever situate, the pellagrous dermatitis must occur in the territory supplied by a cutaneous nerve, but the outlines of the skin eruption, with the clear-cut, horizontal upper margins on the arms, do not conform to the outlines of segmental areas as described by Head and others.

As mentioned above, the influence of sunlight in determining the distribution of the dermatitis is undoubted, but pressure also appears to play a part—as witness the frequent occurrence of the dermatitis on the pressure points about the elbows, where the rash may sometimes be recognised when it has practically disappeared from other regions.

The Nervous Symptoms.

Increasing neurasthenia may be an early—sometimes the earliest—symptom of pellagra. With each exacerbation of the disease the condition may become more pronounced, and finally merge into actual insanity. The details of some of the British cases appear to corroborate this march of events, but in some instances a mental breakdown has preceded the appearance of the dermatitis, whilst in others acute insanity has declared itself within a few weeks or months of the appearance of the rash. Rapid and pronounced mental degradation has characterised a few cases from the very beginning of the disease.

The neurasthenic symptoms which have been recorded include obstinate insomnia, recurrent headaches, vertiginous sensations, lassitude, deadly and increasing weakness. These may be accompanied by paræsthesiæ, chiefly of a burning type. The neurasthenic symptoms often declare themselves before the appearance of the dermatitis, and, like it, may be more or less in abeyance during the winter season.

As regards affection of the cranial nerves, difficulty and indistinctness of articulation have often been noticed; the pupils, although retaining their reactions, are sometimes unequal, and nystagmus may occur, but it does not appear to be common.

A tremor, which, as a rule, is not very coarse, may be noticed in the hands and arms. Sometimes it involves the head, and also the tongue. Abrupt jerky contractions of the muscles are, I believe, very characteristic, especially when they occur in conjunction with tremor. These contractions are probably of the same nature as the subsultus tendinum seen in very acute cases, and may have given rise to the expression "choreiform movements" used in some descriptions of the disease. Muscular cramps may be present.

Sooner or later symptoms indicating degenerations of the posterior and lateral columns of the cord may make their appearance. This is the "central neuritis" of the American authors. The legs are stiff and the gait becomes spastic, or shows a combination of spasm and ataxy. The patient, if able to get about, shuffles along and shows a tendency to stagger. The knee-jerks are increased, sometimes ankle clonus is obtained, and an extensor plantar reflex is not unknown. Pes cavus and other contractures may develop. In some cases, however, the knee-jerks have been found unequal and difficult to elicit. The arms may participate in the muscular rigidity and reflex increase.

The occurrence of burning sensations in the limbs and abdomen and tingling of the feet has been noticed. Gross defects in sensation have not been described, but slight analgesia may occur. Occasionally some tenderness of the peripheral nerve trunks may be elicited, and tenderness alongside the vertebral spines is common. Incontinence of both urine and fæces may occur in grave cases.

Definite cerebral seizures in the form of syncopic attacks and attacks of tonic rigidity have been recorded. The latter may be of cerebellar origin. No changes have been detected in the cerebro-spinal fluid obtained by lumbar puncture.

The mental symptoms of pellagra are a distressing feature of the disease, but it is impossible to recognise a typical pellagrous insanity. The disease is especially common, for some obscure reason, among the chronically insane. This has led to a great deal of speculation as to the relation between pellagra and the psychoses. Some go so far as to say that pellagra by itself can only produce delirium such as is seen in infective and toxic states, but admit that, like other intoxications, it may act as the exciting cause of acute mental outbreaks in patients who are for other reasons susceptible. Be this as it may, the fact remains that acute mental disease may precede the pellagrous eruption for a few weeks or some months, or may make its appearance subsequent to the dermatitis. Recurrence of the mental symptoms does not necessarily occur with the recurrence of the rash. The mental disorder is in some described as mania, in some as melancholia either stuporous or agitated; sometimes it is of the manic-depressive type, and sometimes it is designated confusional insanity

or exhaustion psychosis. Hallucinations of sight and hearing may occur; delusions have been noted. Refusal of food often necessitates tube-feeding, and a suicidal tendency should be borne in mind.

COURSE AND DIAGNOSIS.

Asylum cases of pellagra include the most hopeless types of the disease, and so may give a very erroneous idea of the general prognosis. It is probable that many attacks of pellagra are so mild and the constitutional symptoms so vague that medical advice is not sought. Some of the cases recently reported have been comparatively slight. On the other hand, several of the fatal cases seem to come into the category of "typhoid pellagra." This is characterised by rapid evolution, by fever, which is insignificant in ordinary cases, extreme prostration, pronounced nervous symptoms, diarrhœa, incontinence of urine and fæces, acute nephritis and muttering delirium or mania. "Typhoid," or "malignant," pellagra may be the termination of more or less chronic cases, which have lasted for years, or declare itself early in the evolution of the disease.

When the diagnosis of pellagra is once made in an asylum or institution other cases are soon recalled as having shown similar symptoms. This, the experience in 1909 in Illinois, has recently repeated itself at Napsbury Asylum.

Early diagnosis is important. In pronounced cases with the pellagrous triad, recognition is not difficult; but in the absence of dermatitis the correct explanation of the digestive and nervous symptoms is easily overlooked. Blood examinations have proved of no assistance, a slight secondary anæmia and an increase in the lymphocytes being the only changes found.

THEORIES AS TO THE CAUSE OF PELLAGRA.

There are few diseases which have been the subject of more speculation, and latterly of more experiment, than has pellagra. A very brief account of the older ideas held as to its causation and of some recent speculations must suffice.

Three chief schools of belief have crystallised—these may be designated the Zeistic, the Zeitoxic, and the Anti-zeistic or Parasitic.

The Zeistic suspicion that maize (*Zea Mays*) in some way causes pellagra is said to be almost as old as the disease itself. The fact that certain rodents when fed on sound maize develop ill-health and gastro-intestinal disturbance is held to indicate the presence of a toxic constituent in the grain. But there is no evidence that the disturbance thus produced is genuine pellagra.

Neither has pellagra been proved to be the result of mere under-nutrition induced by a maize diet. Chemical analyses yield no support to the idea that maize is poor in ordinary nutritive substances, seeing that it is nearly four times as rich in fat as wheat itself and that its protein content is greater by one-fourth than that of the latter cereal. Certainly one important fact is forthcoming, and that is that a peculiar maize protein "zein" contains no tryptophane; but zein is not the sole protein of maize. Lately pellagra has been suspected of being a deficiency disease—like scurvy or beri-beri—but, so far as the scurvy vitamine is concerned, there appears to be no lack in the grain. Casimir Funk has pointed out that maize is more thoroughly decorticated in America, where the disease is very severe, than in Italy, where the disease exists now in a more chronic form.

One group of Zeists has suggested that pellagra is a photo-dynamic disease, due to the development of a toxin which is generated in maize feeders by the action of actinic rays on a circulating maize lipoid.

The Zeitoxic school is a later development of the zeistic creed. This is the school of Lombroso, and its tenets may be summarised as follows: In pellagra we are dealing with an intoxication produced by poisons which are generated in spoiled maize by the action of certain moulds which in themselves are harmless to man. The idea is that not in sound but in spoiled maize must the cause of pellagra be sought, and that by preventing the consumption of such maize pellagra is to be eradicated.

Adherents of the Parasitic theory may roughly be divided into two groups—those who believe that maize is at least a vehicle of infection, and those who urge that maize has nothing whatever to do with the disease. Those parasitists who regard maize as a vehicle look upon certain moulds as pathogenetic—viz., Aspergillus fumigatus, Aspergillus flavescens, or Penicillium glaucum, and assert that maize free from these organisms does not produce pellagra. The group which discards maize altogether seek for the cause of pellagra in micro-organisms, amœbæ, filariæ, or protozoa. According to Sambon, pellagra is related to the running stream much as malaria is related to the marsh, and he surmises that a biting, two-winged fly, Simulium, which passes its early developmental stages in running water, stands in the same relation to pellagra that the mosquito does to malaria.

On the other hand, it is worthy of note that a close connection was found by Jennings and King in America between the incidence of pellagra and the amount of time spent in and about the house. Of the cases investigated 75 per cent. were females. These observers suspect the stable-fly as a carrier.

It may be stated that in none of the British cases was maize a staple article of diet. Most patients have denied ever having taken it at all. Some have eaten "pop-corn."

Of late years many attempts have been made to infect monkeys by the tissues and fluids of pellagrins. The members of the Illinois Pellagra Commission thought they were successful in the case of certain Rhesus monkeys, but found later that they had been deceived by the erythema and œdema which normally appear in the perineal and genital regions of these animals during the period of sexual activity.

Using monkeys of the same kind, workers in the laboratories of the Tulane University, New Orleans, now claim to have produced the cutaneous lesions and other signs of the disease.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Dr. Savariaud, Surgeon to the Trousseau Hospital, Paris. Subject "The Osseous Articular Manifestations of Inherited Syphilis in the Child."*

ORIGINAL PAPERS.

CHRONIC INTESTINAL STASIS. (a)

BY SIR W. ARBUTHNOT LANE, BART., M.S., F.R.C.S.ENG.,

Senior Surgeon to Guy's Hospital, and Emeritus Surgeon to the Hospital for Sick Children, Great Ormond Street, London.

BY chronic intestinal stasis is meant such a delay in a portion or portions of the gastro-intestinal tract as results in the absorption into the circulation

(a) Abstract of lecture delivered before the Glasgow Medico-Chirurgical Society, January 16th, 1914. Specially reported for this journal.

of more toxic matter than the organs whose functions are to convert, convey and eliminate it, can deal with. In order to understand the changes that take place in our drainage scheme because of the peculiar mechanical relationship of our bodies to their surroundings in the condition we speak of as civilisation as opposed to that in which we were originally evolved, the general mechanical principles which influence the growth of the skeleton and soft parts must be considered. Three general laws determine evolution, and are readily illustrated from the anatomy of labourers who have borne a special mechanical relationship to their surroundings. These are (1) that pressure produces changes in the form and structure of the bones and soft parts. Thus in the case of a brewer's drayman, whose function it is to carry barrels on his right shoulder, the spine and ribs come to form a shelf on which the load rests. The economy in expenditure of energy arising from this evolutionary process is enormous. The vertebræ are ankylosed together, the heads of many of the ribs are locked to the spine, the costal cartilages are rigid or ossified, and respiration is carried on solely by the abdominal muscles. This condition illustrates, as do all the labour and other evolutionary changes, that the beginnings of these changes are advantageous to the individual, but that later their result is disastrous. The life of the heavy labourer is shorter than that of the man who does not lead a laborious existence, because the changes which enable him to perform his special functions as economically as possible render him unfit to battle with disease. Let such a labourer get pneumonia or bronchitis and he succumbs much more readily than the individual whose thoracic respiration is normal. The "spondylolisthesis," which develops in the skeleton of a coal-heaver, illustrates the same law. (2) Strain produces change. This law is illustrated by the change in form which ensues in a flat bone like the scapula under the influence of special strain, as in the case of a sweated shoemaker. (3) Apart from pressure and apart from strain an entirely new mechanism may be developed or an old one modified, in either case with the object of economising the expenditure of energy. This is illustrated by the changes which develop in the occipital bone, atlas and axis of a shoemaker, and in the elbow-joint of a coal trimmer.

The mechanism of chronic intestinal stasis is as follows: The condition is primarily a stasis in the large intestine or cesspool of the gastro-intestinal tract. This is most marked in the cæcum, ascending colon and sigmoid. The sigmoid, with its solid contents, tends to fall into the pelvis, where it interferes with the functions of the viscera which normally occupy that space. At an early date resistances to this prolapse are crystallised in the form of bands which are attached to the outer surface of the meso-sigmoid, fixing the mesentery and later the iliac colon as a straight rigid tube to the floor of the fossa. These bands are specially marked at the junction of the iliac with the pelvic colon where the bowel is more fixed than elsewhere. This particular thickening performs the function of preventing the regurgitation of fæcal matter from the pelvic into the iliac colon. It is the "first and last kink," as it is the first to develop and is the lowest kink in the gastro-intestinal tract.

This kink frequently attaches itself to and secures the fimbriæ of the Fallopian tube and the ovary, interfering materially with their functions, and the ovary, when buried in the adhesions, often develops cystic changes. The fixation of the iliac colon in the iliac fossa as a straight conduit, while at first of advantage, causes sooner or later wasting of the muscle wall of the bowel and obstructive changes, with the consequent production of hernial diverticula or inflammatory change. Later a carcinomatous infection may result.

As regards the cæcum, it tends to be displaced by hydraulic pressure in the erect posture of the trunk into the true pelvis, and this tendency is specially marked in women, who are longer in the abdomen and bigger in the pelvis than are men. Nature attempts to oppose the descent of the cæcum by the crystallisation of lines of resistances in the form of acquired or evolutionary bands or membranes in whose development inflammation plays no part. "Jackson's membrane" consists of bands which run upwards and outwards and sling the cæcum to the adjacent peritoneum of the abdomen. Involvement of the appendix in one of these bands may produce "appendicitis." Another band or membrane is developed in and along the posterior wall of the mesentery which holds up the termination of the ileum, by which not only is the lumen of the ileum kinked at one point, but is also twisted in itself so that it is still further occluded. In this band also the appendix may be involved. Obstruction to the passage of the contents of the ileum into the cæcum has the following results: Material accumulates in the small intestine and exerts a drag upon the vertically placed termination of the duodenum. The duodenum in consequence dilates and changes take place in its mucous membrane, which are exaggerated by the infection of the intestinal contents resulting from their delay. Engorgement of the mucous membrane is followed by inflammation, abrasion and ulceration. The hepatic and pancreatic ducts are also infected, and changes of an inflammatory and later of a cancerous nature develop in the pancreas. Gallstones are formed in the gall-bladder, which may produce cancer, and the infection of the hepatic ducts changes the secreting power of an organ on which excessive demands are made habitually. Spasm of the pylorus is developed to prevent the passage of the compressed duodenal contents back into the stomach, while the contents of the stomach are dammed back and changes consequent on gastric distension ensue—degenerative and inflammatory changes in the mucous membrane, with, later, ulceration and cancer.

Stasis results in the absorption into the circulation of a greater quantity of toxic material than can be treated effectually by the organs whose function it is to convert them into products as innocuous as possible to the tissues of the body. An excess of such products in the circulation produces degenerative changes in every tissue and organ. If operations on the drainage scheme had done nothing more than demonstrate the damage done by these poisons, the remarkable power of repair which the tissues exhibit on being freed from their malign influence, and the extraordinary improvement in the functioning of the organs of the body after operation, they would have been fully justified. Thus pigmentation of the skin is a very marked feature in advanced cases of stasis, especially in patients with dark hair; but on eliminating the supply of poison the brown or coppery tint rapidly disappears and is replaced by the warm red colour indicative of health. Again, following on the exclusion of the large bowel, the cold, blue, clammy hand is replaced by a nice warm, pinkish, dry one. In the case of the kidney affected by so-called Bright's disease, which is merely a product of chronic intestinal stasis, the exclusion of the large bowel is followed by an improvement in functioning, which is as extraordinary as it is rapid.

In chronic intestinal stasis, in the female, the breast is indurated and knobbly; eliminate the

supply of toxins and a soft, healthy organ results. A breast in a healthy subject showing no evidence of stasis does not become cancerous. The influence of these toxins on the nervous system is illustrated by the case of a woman who had been confined to bed for many months, and whose mental condition was such that she was regarded by many as an imbecile: within a few weeks of the removal of the large bowel she became a happy, active, intelligent woman, and has since lived a useful life, earning her living. A woman who had suffered for nine years from epileptiform neuralgia of the right fifth nerve, was sent from South Africa to have the Gasserian ganglion removed. She was definitely static, and her symptoms varied with her toxicity. She was short circuited, with the result that all symptoms disappeared and her general health and weight improved rapidly. In another patient, a man, intense headaches associated with vomiting, suggestive of cerebral tumour, disappeared abruptly after an ileo-colostomy. Removal of the large bowel in another case was followed by very rapid subsidence of a large adenoma of the thyroid, and typical symptoms of exophthalmic goitre of long standing associated with intestinal stasis have rapidly and permanently disappeared in other cases. The extraordinary improvement that results from short-circuiting and the disconnection or removal of the large bowel does not mean that the colon is the chief source from which toxins are absorbed in excess. Indeed in a considerable proportion of cases the bulk of the absorption takes place from the small intestine. The improvement is largely due to the fact that the evacuation of the small intestine is facilitated by its introduction into the pelvic colon, so that the infection of its contents by organisms which grow in the stagnating material in the large intestine ceases abruptly, and the production and absorption of toxins, therefore, no longer take place.

THE MEDICAL ASPECT OF ANTARCTIC TRAVEL.

By GEO. MURRAY LEVICK, R.N., M.R.C.S., L.R.C.P.,
Surgeon to the National Antarctic Expedition, 1910.

(SPECIALLY REPORTED FOR THIS JOURNAL.)

ON Monday, January 26th, Surgeon Murray Levick delivered, to the accompaniment of a beautiful collection of slides, a lecture before the Royal Society of Medicine, entitled "The Experiences of Captain Scott's Northern Party from a Medical Point of View." The chair was occupied by the President of the Society, Sir Francis Champneys, and the large hall of the society was quite filled.

Surgeon Levick said it had been suggested to him that as the Northern Party lived for some time under unusual conditions, it might be of interest to members of the profession to hear about them. The party consisted of six members, Commander Campbell (in command), Surgeon Levick, Mr. Priestley, and three petty officers of the Royal Navy. They left New Zealand at the end of November, and a month later they encountered pack ice, which detained them five weeks. Then they came to Ross Sea, and landed at Cape Evans. Captain Scott made his winter quarters near the foot of Mount Erebus. Ponies and dogs were taken for haulage purposes, but the latter were so far superior that it was probable only dogs would be taken in future. They were of the Siberian domestic variety. The face of the barrier was too precipitous to admit of stores being landed, and a large pack prevented progress further East. In the Bay of Whales they found *The Fram* alongside a narrow neck of sea ice. A note was left for Captain Scott, and the party made for Robertson Bay, where Sir George Newnes' expedition spent the winter. On landing they built their hut, the planks for which had already been cut up and numbered for the purpose. The winds were terrific, often 100 miles per hour, and occasional gusts much more than that. It was impossible to walk in the wind, and it was necessary to progress on all fours. The hut had to be secured by means of wire hausers anchored to stakes driven deeply into the ice. The seas were very heavy, and huge boulders were flung up by them; and these subsequently became frozen together in large masses. In a couple of days ice formed to a thickness of 18 inches, enough to allow a sledging party over. There were four months of darkness, during which it was impossible to get away from the beach. The clothing for the spring—the time of severest winds and most intense cold—consisted of woollen trousers and vest, over those a woollen jersey, and a cotton wind-proof garment over all. On the feet were two or three pairs of socks, covered by boots made of reindeer hide. They also wore a wind-proof helmet. A woollen nose-piece had also to be worn, because of the liability of that organ to be frost-bitten. One had to be very careful about putting the snow shoes into a good position on taking them off for the night, otherwise they were frozen hard and took a long time to thaw into shape. It was found to be impossible to get up any of the glaciers, which were of enormous height. The Antarctic climate was very treacherous. A day would open beautifully fine, and the decision would be formed to have a day's sledging, but within twenty minutes a great blizzard would come on, with practically no warning, so that it was impossible to see a yard ahead. On one occasion the party were imprisoned four days in this way. It was not safe to go any distance without sleeping bags. It had been arranged that they should go for a six months' sledge journey and come back to meet the ship on her return South. After making several expeditions, they returned to their rendezvous to await the ship, towards the end of February. But the ship was stopped by an enormous hang of pack ice 30 miles away; and after trying very hard to reach the party, had to give up the attempt. As it was getting late in the year, it seemed likely that the little party would be frozen in. After waiting a further month, they had nearly given up hope. The country they were in was very unsuitable for living in, because, owing to the constant winds, the country was swept almost bare of snow; there was occasional bare rock and clear blue ice. Later the winds became incessant, and were of hurricane force; and the temperature was very low indeed. When it was quite obvious that the ship could not get to them, they had only three weeks' full provisions left, and they were 220 miles from the main base at Cape Evans. With regard to a habitation, there were no materials available for building a hut, and they decided to burrow underground. Their only hope of food was to lay in seals. There occurred a blizzard which lasted 13 days, during which time they were scarcely ever out of their sleeping bags. They

decided to keep three weeks' provisions for the journey back, making up their food while in quarters entirely from seals. They also killed 70 or 80 old moulting penguins, which were all that remained of a very numerous rookery. They then laboriously burrowed through a snowdrift into clear blue ice, and cleared a space 12 ft. by 5ft. 6in. by 4ft. It was a very frequent occurrence to have the toes frost-bitten, chiefly the big toe. Their food consisted of seal meat and one biscuit a day. It took some time to get accustomed to the blubber, as it had a very strong flavour. It was found impossible to satisfy the appetite solely on lean meat, however much of it they ate. There was just room in the "igloo" to take the party lying down and a corner for cooking. A rope was teased out to be used as a wick for a lamp, in which was burned blubber. It gave a yellow odorous flame, and had to be snuffed every five minutes to keep it going. As a stove they used the bottom of an oil tin, and the heat was provided by dropping blubber on to bones. When the temperature was minus 10 or 15 degrees they had to break off the seal meat by means of a geological chisel-hammer. At first they ate as much seal meat as possible, and as a result they had some unpleasant symptoms. They missed carbohydrates very much. During seven months the party had very little exercise. A serious event was the practical exhaustion of their supply of salt. They substituted ice-salt, but that started an epidemic of diarrhœa. As there was some question about it being the cause, the small remaining stock of salt was used, and the diarrhœa disappeared, only to return when ice salt was again consumed. With regard to scurvy, they had all the conditions conducive to that disease except in the matter of food—very uncomfortable surroundings, depressing conditions, very little exercise, and bad air—yet they did not suffer from scurvy. He concluded it was impossible to get scurvy so long as one was living on fresh meat. When living on large quantities of seal meat they had large quantities of uric acid in the urine, and the passage of the crystals caused much pain. Also several members suffered from enuresis while in their sleeping bags, and it took a long time to thaw the soaked garments. The desire to micturate became very acute, even when there was small reason for it, and urination was so precipitate that they often had not time to get on their wind-proof clothing and go outside. The symptoms subsided on subsequent enforced low diet. Later still they had severe constipation, and difficult motions at intervals of three days or more. Several members consequently developed fissures and had hæmorrhages. A member would be absent from the igloo forty minutes, and come back in considerable pain, and remain so for hours. They were then able to kill three more seals, and were again in plenty. The result of eating heavy meals was a return of the uric acid and other symptoms. They then tried boiling all the meat for half-an-hour before cooking, and the symptoms disappeared. Probably a great deal of protein material had been passing through the intestines without being assimilated. The roof of the igloo, during the earlier period of the occupation, consisted of driven snow, and probably oxygen was diffused through that from above, as the two doors for ingress and egress were securely fastened. But a severe blizzard, coupled with some glazing due to a partial thaw by the warmth and re-freezing, shut off this supply of oxygen, so that the stove, the lamp, and even the match refused to burn. Yet the party had suffered no ill effects, and had not even a headache. They now cut through the snow above the sleeping space and formed a chimney. The lecturer felt quite convinced that their health under these circumstances was due to the stimulant effect of the intense cold—warmth with so much vitiated air would have been quite intolerable. Five months were spent under those conditions in comparative well-being, but afterwards they felt themselves going downhill, and so determined to leave on September 30th. Three weeks before that they commenced Swedish exercises, and by the starting date they were more fit than they expected to be. The first three days they did very good marching, but later on they felt very stale. They were living on seal meat with two biscuits a day. After three weeks' marching they found a depot with various luxuries which had been left by Mr. Griffith Taylor's geological party: the butter, lard, and chocolate they ate like apples, and each made a prodigious meal, yet awoke in the night as hungry as ever, and ate again. One result was that a member of the party who had been ailing was well in 24 hours after partaking of the good things, and remained well to the end. All the remedies available had failed to effect the good produced by this food. Several days hereafter they marched 16 hours a day, with only brief halts. They felt tired, but very fit. They arrived at the base on November 2nd, the journey having occupied five weeks.

The President cordially thanked the lecturer in the name of the meeting, and commended the party for their pluck, endurance and cheerfulness.

THE PRESENT STATE OF THE STUDY OF BERIBERI IN JAPAN. (a)

By Dr. S. SHIBAYAMA,
Tokyo.

The Commission for the study of the cause and prevention of beriberi, formed in 1908 in consequence of the fierce epidemic which broke out in the Japanese army during the late war, deemed it necessary to determine what relation exists between the two allied diseases kakké and beriberi. Two other members of the Commission and myself were sent to the Dutch Indies and the Straits Settlements with this object, and have come to the conclusion that they are identical. Moreover, we introduced an experimental study of the beriberi-like disease in birds and its prevention by feeding them on either 'red' or cured rice, as is carried on in the Dutch Indies. Five years have elapsed since the commission was first formed, and various reports have been published, which, for the sake of convenience, may be classed as follows: 1, Experimental study of the beriberi-like disease in birds; 2, prevention of beriberi with cured rice or a mixed diet consisting of rice and barley; 3, epidemiological observations. In the present paper it is intended to cite briefly the results hitherto obtained.

I. Experimental Study of the Beriberi-like Disease in Birds.

1. Fowls, especially hens, pigeons, etc., die of

(a) Original communication read before the Section of Tropical Medicine and Hygiene at the International Medical Congress, London, July, 1913.

a beriberi-like disease when they are fed with "white" rice (*i.e.*, rice the bran of which is separated by pounding it in a kind of mortar, so that it presents a semi-transparent colour), but the administration by the mouth or subcutaneous injection of rice-bran or its derivatives, *e.g.*, alcoholic extracts, will cure them. All experimenters agree in this.

2. As to the cause of the beriberi-like disease in birds that is contracted by feeding on white rice, the Japanese workers disagree wtih Schaumann and Fraser, who advocate the phosphorus starvation theory. Though the insufficient phosphoric contents of white rice may cause kindred symptoms in animals, the true cause is held to be other than phosphorus itself. Dr. Suzuki, chemist, attributes the disease to the lack of a material called "aberic acid," which he removed from rice-bran by a complicated method; for even a small dose of this acid—*i.e.*, 0.005 mgr. daily, will protect a 300 gr. pigeon fed with white rice from contracting the disease.

3. Others hold the zymotic hypothesis. They attribute the disease to a toxin produced by the fermentation of white rice, and not to the deficiency of a certain kind of nutriment. This hypothesis is based upon the results of an experiment in which fowls contracted a beriberi-like disease, similar to that caused by feeding on white rice, from an injection of a fermentative product of white rice; they were led to this by the fact that the heart of a frog will stop in diastole if it is immersed in a fermentative product of rice produced by a certain kind of enzyme, just as it will in the milk of a beriberic woman.

4. Our Japanese erperimenters may be divided into two schools. One considers the beriberi-like disease in birds caused by feeding on white rice to be identical with human beriberi, and tries to explain the causes and features of human beriberi by the conclusions arrived at from experimental studies in birds, while the other thinks these two diseases are quite independent

The one points to the fact that clinically in the beriberi-like disease in birds there are seen paralysis in the ascending motor nerves, œdema, tachycardia, and dyspnœa, and, anatomically, degenerative changes in the peripheral and central nervous system, dilatation of the heart, and stasis in the veins, just as in human cases. The other (the majority) disagree with the first on the ground that although bird-beriberi may present similar symptoms and anatomical findings to a certain degree, it does not always do so, and, moreover, beriberic birds develop not only numbness but also rigidity in the neck, which is never met with in human cases. The curative effect of rice-bran and its derivatives upon bird-beriberi seems to afford the most interesting analogy to human beriberi, for it would serve to a large extent to establish the identity of the two diseases. Many experimenters agree that these substances do not cure human beriberi, or at most, they do not think that they have brought about such a marked improvement in the human as in the birds' disease.

If we admit the conclusion reached by the latter school, we see that the study of the beriberi-like disease in birds has but little to do with the discovery of the causative agency of human beriberi.

II. EXPERIMENTAL STUDY OF THE PREVENTIVE EFFICACY OF CURED RICE AND A MIXED DIET, CONSISTING OF RICE AND BARLEY, UPON HUMAN BERIBERI.

The members of the Japanese Beriberi Commission observed an outbreak of beriberi among the tin-miners at Brinjoe tin-mines in Banka Island, East Indies, who were served with newly husked rice, in spite of the hypothetical preventive property of cured rice. They therefore resolved to test it upon people who had been liable to infection. The experiments were carried out in coal mines where the miners had been yearly affected most severely, first in Hokkaido in the northern, and in Kiushiu in the western island, and then in a fishing village on the west coast in Central Japan, where the inhabitants had also suffered severely. In these three places the inhabitants were divided into groups consisting of a certain number of persons (usually 100); during the beriberi season (seven months from the beginning of April to the end of October) one group was provided with cured rice, another with the mixed diet consisting of rice and barley, while a third was given white rice as control, the object being to determine which group provided the largest number of patients. It was possible to make the main diet uniform, but unfortunately not the side dishes. The experiment was carried out twice in each of the three places, and produced the following results. The figures shown in the table are the averages of the numbers obtained:—

Main diet.	No. of the inhabitants who had been experimented on.	No. of patients	(in per cent)
Cured rice	657	8	(1·22)
Rice (6 parts) Barley (4 parts)	534	19	(3·56)
White rice (control)	710	64	(9·01)

It will be seen from the above table that neither the cured rice nor the mixed diet of rice and barley is able absolutely to prevent the disease, though they seem to play some part. Another instance in which they were unable to hinder the onset of the disease is seen in the following table:—

Main diet.	No. of the inhabitants who had been experimented on	No. of patients.
Cured rice	100	5
Rice and Barley	100	4
White rice	100	7

III. EPIDEMIOLOGICAL OBSERVATIONS IN BERIBERI.

In Japan every year there is a long list of cases and deaths from beriberi in the cities, but the disease never becomes epidemic. It appears only sporadically like typhoid fever. However, in particular villages or ships a severe outbreak often takes place. Coal-miners, fishermen, railway labourers, and prisoners are the classes among which the epidemic rages. A few years ago, over 10 per cent. of coal-miners in Hokkaido and Kiushiu suffered from the disease. Fishermen in certain regions—*e.g.*, the eastern coast of Idzu peninsula and Hejima island in Noto province have been severely affected. On Hejima island particularly no case of beriberi had been known until one appeared quite recently. A year later the islanders suffered severely from the outbreak, which has since shown a gradual decrease. Among the fishermen on the eastern coast of Idzu peninsula it appears only sporadically for a few years with recurring fierce epidemics. The crews of "out"-fishing vessels sometimes suffer greatly. In 1912, among 193 comprising the crews of nine such vessels bound for the northern seas, 93 cases besides 29 deaths occurred. Again, 62 immigrants for Peru were rejected and sent back to Yokohama, and thus were made to spend 139 days on the same vessel. On their homeward voyage they were all stricken with beriberi and 6 died. In this case the so-called "ship-beriberi,"

or scurvy, was suspected, for they were living under surroundings favourable to the onset of this disease, but the absence of hæmorrhages in the gums or other symptoms was unmistakable evidence of its having been genuine beriberi.

Epidemics among the railway labourers occur only when they live together in a small hut and engage in work far away from intercourse with others.

Prisoners, nowadays, are rarely infected with beriberi. Only one instance occurred two years ago in a prison in Korea, where a number of prisoners contracted the disease simultaneously.

The causative relation which is supposed to exist between rice and beriberi has been studied most carefully in all the above-mentioned epidemics. Most of these prevailed among people who ate rice, but some raged among those who took a mixed diet consisting of four parts of rice and six parts of barley. From the facts that have been given in the previous paragraphs, some arrive at the conclusion that rice is perhaps the cause of beriberi, but they cannot deny the fact that all the labourers who eat rice and live in the same surroundings do not contract the disease. The seasonal prevalence of the disease is established; it begins to appear in May or June, and reaches the maximum during the three months July, August, and September, and finally disappears of itself when the cool autumn sets in. It will break out in great numbers in one year, while no case occurs in another even though the inhabitants have the same main diet and régime. Again, it will appear in one season and disappear in another under the same conditions. This seasonal prevalence is noticed in almost all epidemiological observations of the disease.

Resume.

Those who are studying beriberi have not yet been able to arrive at any conclusion. Rice as well as a monotonous and one-sided diet may give rise to the onset of the symptoms, but they cannot be assumed to constitute the cause of the disease. The symptoms and anatomical changes seem to develop from intoxication by a poison which is produced by a certain kind of micro-organism in the human body, especially the intestine. This hypothesis may explain the geographical and seasonal prevalence, for if the disease were caused exclusively by deficiency of a certain kind of nutriment, we do not see why it should not occur among other nations as well as the Far Eastern.

THE STUDY OF DISEASE IN THE DOMESTICATED ANIMALS: ITS IMPORTANCE TO THE COMMUNITY.

WITH A PLEA FOR AN ANIMAL HOSPITAL. (a)

By ERNEST GLYNN, M.A., M.D.Cantab., F.R.C.P. Lond.,

Professor of Pathology, Bacteriologist and Pathologist, Liverpool Royal Infirmary.

Readers of Kipling's story, "The Cat that Walked," know just how the domestication of wild animals first began long ago, when "the Dog was wild, and the Horse was wild, and the Cow was wild," and "they walked in the Wild Wet Woods all by their wild lones"; and how the Man was wild, too, dreadfully wild, till he met the Woman; and how she also tamed Wild Dog, so that he became the "First Friend for always and always and always," and how Wild Cow became the Giver of Good Food, and how Wild Horse submitted to the plaited-hide halter; "but the Cat he walked by himself."

(a) An inangural lecture delivered before the University of Liverpool on Friday, February 21st, 1913.

The first friend and the horse were domesticated thousands of years ago, for their bones are found in the Neolithic age of Europe, mingled with those of the cave-men, with whom they shared pleasures, pains, and sometimes diseases. The domestication of the cat took place much later, and was probably first accomplished by the Egyptians; his feline amenities and nocturnal habits have always been regarded with awe and suspicion by savage, and even by civilised races.

We often, I think, fail to realise what a debt our civilisation owes to the ungrudging assistance of the domestic animals. They feed us, clothe us, transport us to the ends of the earth, and carry us to battle; they are our pets, companions, protectors; they amuse us, hunt with us, and race with us; they live with us and die with us, and their bones enrich our soil and, as some believe, their spirits accompany us to a better land.

Consider the vital importance of the domestic animals to the largest British industry, agriculture, which still employs nearly a million and a half workers. Though this is not a political meeting, I am obliged to quote statistics, all taken from the Board of Agriculture's Reports, published 1912:—

The number of horses used in Great Britain during 1911 for agricultural purposes was very nearly a million and a half, a diminution of only 7,000 in the last five years in spite of the advent of motor traction. There were 26½ millions of sheep, 7 million cattle, nearly 3 millions of pigs, and 2 million dogs. The total number of these five animal species, including those horses used for traction, is nearly equal to the human population of the British Isles.

Take dairy farming. The quantity of milk produced in Great Britain during 1907-8, after allowing for that used in calf-rearing, was 1,200 million gallons. The total amount of milk actually sold by the farmers was valued at 25 million pounds sterling, the butter at 3 million pounds, and the cheese at 1½ million.

On June 4th, 1908, there were 32,356,000 fowls, 2,963,000 ducks, 712,000 geese, 697,000 turkeys in the farms of Great Britain alone. These obliging birds were estimated to have produced 1,139,293,000 fresh eggs in a single year, a number which, adopting the methods used by astronomers to illustrate the immensity of the heavens, if placed end to end would reach about twice round the earth!

With figures like these it does not require much imagination to realise how intimately our country's welfare is bound up with the health, strength and happiness of the domestic animals, and how the death of a cow from anthrax, the laming of a horse from spavin or shivering, or the quarantine of a seaport owing to foot-and-mouth disease, is a loss to the national wealth.

PART I.

Infective Diseases of Animals Communicable to Man.

I shall now touch upon some of the diseases which afflict the domestic animals, alluding specially to the present state of our knowledge, or often ignorance, concerning them; secondly, their cause, their prevention, their cure, if any; and thirdly, indicate their economic importance.

The first group are the infectious diseases which may be communicated to man either directly by contact, or indirectly by milk, meat, flies, fleas, etc.

Tuberculosis.

Tuberculosis, the great white plague, kills both man and brute. The human death-rate in England and Wales was 51,317 in 1910, viz., over 200 per 100,000, though it has diminished by one-half in the last thirty years.

Tuberculosis destroyed enormous numbers of cattle and pigs. Sheep and goats, dogs and cats, the horse and the ass are no more immune.

Delépine estimates that the number of tuberculous cattle in Great Britain is 1,600,000; Brittlebank, that

the annual loss to dairy farmers in England is nearly one million pounds; while Melvin estimates that the yearly tribute paid in farm animals in the U.S.A. is £2,800,000.

Systematic bacteriological investigation of the milk in Liverpool, Manchester, Birmingham, and London in 1908 demonstrated the presence of tubercle bacilli in 3.2, 5.1, 7.5, and 10.4 per cent. respectively of samples examined. It is estimated that at least 2 per cent. of the cows in Great Britain have tuberculous udders.

During the latter half of the last century it was generally accepted that tuberculosis is communicated to man by the domestic animals, especially by cows' milk. However, in 1901, Koch, discoverer of the tubercle bacillus, startled the medical world by stating that human and bovine tuberculosis were different diseases, and that the bacillus from the cow so rarely infected man that its presence in milk and other food was of little importance.

An enormous amount of research has been undertaken to test the truth of Koch's assertion. The most comprehensive investigation is that of the Tuberculosis Commission, which has recently published its report, after ten years of patient work—a report which is a monument to British bacteriology. It is pleasing to remember that Sir Rubert Boyce was one of the Commissioners, and Drs. A. S. and F. Griffiths, two of the investigators, were graduates of this University, and worked for several years in our pathological laboratory, before joining the Commission.

The Commissioners demonstrate that Koch's statement was inaccurate, and they are supported by the great majority of investigators all over the world.

They prove that tubercle bacilli found in cattle and man respectively are two different varieties of the *same* bacillus, and the disease they produce is the *same* disease; secondly, that bovine tuberculosis does infect man, and is responsible for a large amount of tuberculosis in children, which is usually contracted by drinking cows' milk. Lastly, the Commission urge the Government to take steps to eliminate tuberculosis from the domestic animals, and so reduce the amount of human tuberculosis.

It must be remembered that not only milk, but also cream and butter may contain living tubercle bacilli, though in most cheeses they are probably dead.

Animal tuberculosis, like human, is more common in bad hygienic conditions—as deficient ventilation, overcrowding, unwholesome food, etc. Its recent increase amongst cattle is partly attributed to railways opening up the country, leading thereby to the rapid transport of infected animals from place to place, and partly to the great increase in dairy farming, which crowds cattle into small areas, where they are often kept for a long period under a constant milk-stimulating regimen.

Thanks to careful inspection and the provision of hygienic shippons, only 1 per cent. of the cows actually kept in Liverpool during 1911 yielded tubercle bacilli in their milk, as against 6 per cent. of the cows which supplied milk from the country.

In Scotland, where there is "practically no veterinary inspection at all," bacteriological investigations show that a larger percentage of the inhabitants are infected with bovine bacilli than in England and Wales (Report, Departmental Committee, vol. ii., 1913).

Not only the dairy farmer, but also the stock-breeder, who exports prize animals abroad, suffers heavy losses from tuberculosis. Some authorities believe that England is partly responsible for the introduction of the disease amongst cattle in the United States and the British Colonies, and we find American experts warning their stockmen to beware against infection introduced from Great Britain.

One hundred and fifty thousand pounds worth of live cattle were exported from the United Kingdom in 1911, and if tuberculosis could be eradicated from our stock, the trade in live animals would be enormously increased.

A large amount of research work has yet to be undertaken upon the spread of tuberculosis amongst the domestic animals, and particularly the methods of prevention and cure, and the Government is about to make an organised effort to stamp out the disease.

Tetanus.

Tetanus, or lock-jaw, though a rare disease, is comparatively common amongst horses. It occurs in one out of every six thousand horses in the Prussian Army.

The tetanus bacillus is a normal inhabitant of the intestine of many herbivora, and is also often found in the soil—particularly in manured soil. Man usually contracts the disease from the contamination of cuts, scratches, etc., with dirt; garden earth is especially dangerous on account of the manure it contains.

Tetanus is commoner in the United States than in England, and large numbers of lives used to be lost every year, particularly after the 4th of July celebrations, owing to accidents from fireworks, etc. Tetanus has been contracted from the use of improperly sterilised catgut ligatures in surgical operations.

Antitetanic serum "has been successfully adopted all over the world" for the prevention of tetanus in "wounds of animals, the result of accident or made in the course of stock-breeding" (S. Stockman). New statistics by Labat and Nocard, respectively, strikingly confirm this statement.

When, however, tetanus is fully developed, treatment is of little use.

Glanders.

This is also a common disease amongst horses, and was noted in Greece in the days of Aristotle. It often breaks out during war, when cavalry and artillery horses are crowded together, and greatly hampers the movements of armies.

Glanders is communicable from the horse to man; coachmen are most frequently infected, and it is usually fatal.

Owing to the regulations of the Board of Agriculture, early diagnosis by the Mallein test, and the destruction of all infected animals, glanders is diminishing in Great Britain. Only 504 horses were attacked last year.

Anthrax.

Anthrax is a most deadly disease amongst cattle and sheep, very prevalent in certain parts of Europe and Asia, where its ravages are unequalled by any other animal plague. In the year 1617 sixty thousand persons died in Naples from eating the flesh of anthrax-infected animals.

The disease is comparatively common amongst the cattle in Great Britain, 908 separate outbreaks occurring during 1911—Cheshire and Lancashire being the two worst counties.

The disease is so infectious that the Board of Agriculture compels farmers either to burn or to destroy in quicklime the infected carcases.

Agriculturists, workers in hides and wool, and others who handle the infected material, contract the disease. Bradford, the centre of the wool trade, has an anthrax investigation board, and employs a bacteriologist, who constantly tests the wool for the germs. Analysis showed that 21 per cent. of the samples of hides, wool, etc., imported into Liverpool, which had apparently infected dock labourers and others, contained the spores of the anthrax bacillus (Glynn and Lewis).

The reasons for the spread of anthrax amongst the animals of Great Britain, and its frequent appearance in farms where there has been no previous case, are not yet properly understood. There is much need of further investigation.

Though an animal once attacked with anthrax invariably dies, yet, thanks to Pasteur and others, the disease can often be prevented by protective vaccination. According to Stockman, over "4½ million animals have been inoculated during the last sixteen years in the anthrax-infected districts of France, with the result that the death-rate in infected places from anthrax has been reduced from 10 per cent. to .91 per cent." It has been estimated that cattle and

sheep to the value of 7 million francs have been saved in twelve years.

Hydrophobia.

Rabies or hydrophobia, one of the most horrible diseases, is still common among men and animals, particularly in dogs in Europe and America. No case, however, has occurred in Great Britain since 1903. This was due to a general muzzling order enforced in spite of the strenuous opposition of those who maintain that a "compulsory collar order" would have been equally successful. Rabies still occurs in Germany where a "collar order" is in force and each dog has its "Hundemarke."

In order to prevent the reappearance of hydrophobia amongst men and animals, not only are all dogs, foxes, etc., imported into this country kept in quarantine for several months, but the brain of any dog suspected to have died with hydrophobia is carefully examined in the laboratory for signs of the disease.

Owing to Pasteur's method of treatment, the mortality in human beings has been very considerably lessened, and institutions have been formed for the treatment in Germany, Hungary, New York, India, and many other places. Högyèrs collected statistics of 54,620 persons treated in 24 institutes; the total mortality was only 0.77 per cent. Leblanc, after careful investigation, gives 16.6 per cent. as the mortality among the uninoculated, "an estimate which is generally accepted as conservative and correct" (Osler and McCrae, "System of Medicine," vol. iii.).

Diphtheria and Scarlet Fever.

Diphtheria can be produced experimentally in cats, certainly by direct inoculation, and possibly by feeding. These animals occasionally harbour diphtheria bacilli with or without symptoms of disease, and may consequently infect man; but the number of properly authenticated cases is much fewer than many people believe. Milk may be accidentally contaminated with diphtheria bacilli, but it is doubtful whether cows contract diphtheria and so infect the milk themselves.

It has been asserted that cows develop scarlet fever—the Hendon disease—and may communicate it to man through the medium of milk (Klein). This assertion has been vigorously challenged by some veterinary experts. No cases of Hendon disease have been noted in the United States. The relation of the domestic animals to scarlet fever and especially to diphtheria demands further investigation.

Mediterranean or Malta Fever.

The recent discovery regarding Mediterranean fever is one of the most brilliant in the annals of medicine. The disease, which is exceedingly difficult to cure and often fatal, occurs in India, Africa, China, and Europe. It was particularly common in our garrison at Malta and Gibraltar.

Bruce in 1886 discovered the *Micrococcus melitensis*, and proved it to be the cause of Mediterranean fever, partly by the experimental infection of monkeys; but the mystery and spread of this disease remained insoluble.

In 1904, the Royal Society sent a Commission to Malta to investigate how the fever was conveyed. They proved by experiments that it was not carried by air nor by drinking water, nor by sewage, nor by contact, nor by biting insects. Then suddenly the mystery was solved. Goats' milk was the infecting agent. The Commission found that half the goats in the island were infected with the micrococcus, and 10 per cent. were actually secreting the germs in their milk. Monkeys fed with the milk of these goats almost invariably contracted the disease.

The remedy was obvious. The officers and men in the garrison were prohibited under severe penalties from drinking goats' milk. The result was marvellous.

The average number of cases of Mediterranean fever among the Army and Navy for five years preceding 1906 was 555. In the second half of 1906 the drinking of goats' milk was prohibited, and there were 270 cases of fever. In 1907, 21; in 1908, 11; in 1909, 11; in 1910, 4; in 1911, 9; in 1912, 6. The disease is still very prevalent among the civil population, who persist in drinking goats' milk, for the average number of cases during the five years preceding 1906 was 632, but they had only diminished to 318 in 1910 (Eyre, *Lancet*, 1912, and private communication).

Think of the true significance of this astonishing discovery. Visitors to Malta will remember how the ubiquitous goats increase the picturesqueness of the streets. Yet these harmless-looking, common, domesticated animals, apparently in perfect health, are veritable breeding grounds of micrococci, or "germ carriers," and have been spreading Mediterranean fever for hundreds of years—and no man knew it.

Human beings who have had an attack of typhoid, diphtheria, or cholera may also act as "germ carriers" for months, even years, after their recovery, and so infect their fellows. Several outbreaks of typhoid, for example, have been traced to apparently healthy cooks, soldiers, laundry maids, etc., acting as typhoid carriers.

The spread of the disease from man to man by "germ carriers" is so widely recognised, that it has even attracted the attention of Mr. Punch. I trust I may be permitted to quote some lines by Owen Seaman upon the "germ carrier," which are founded on fact:

"In U.S.A. (across the brook)
There lives, unless the papers err,
A very curious Irish cook,
In whom the strangest things occur:
Beneath her outside's healthy gloze
Masses of microbes seethe and wallow;
And everywhere that Mary goes
Infernal epidemics follow."

Comparatively little is known at present about germ carriers spreading disease amongst animals.

Plague.

The black death which overran Europe in the Middle Ages, and later slew 70,000 of the inhabitants of London in the reign of Charles II., almost disappeared from the civilised world during the eighteenth and nineteenth centuries, although it slumbered in the Far East.

In 1894 a great outbreak occurred in Hong Kong, which spread to India, and eventually reached Europe, attacking the ports of Marseilles, Hamburg, and Glasgow, while isolated cases occurred in Liverpool. When bravely fighting plague in Manchuria, our own graduate, Dr. Jackson, recently lost his life.

Research has taught that plague is due to the *Bacillus pestis*, and that the bubonic form, the common type in Europe, is entirely dependent on the infection of rats, the disease being spread from rat to rat, and from rat to man, by means of the rat flea. Fortunately the rat fleas do not usually bite man.

There have been four fatal outbreaks of human plague in East Anglia within the last six years, where the disease was first introduced into Suffolk by ship rats from plague-infected countries. A few rabbits also became infected.

Precautions are now taken in Liverpool, London, and elsewhere to prevent the ship rats from plague-infected ports coming ashore, while city and port rats themselves are constantly being examined for plague bacilli.

Sleeping Sickness.

Sleeping sickness is a terrible disease in Equatorial Africa, which, partly owing to the opening up of the country, has been ravaging Uganda, Nyassaland, Northern Rhodesia, and the Congo.

In the latter area 100,000 natives have died in three years. Europeans also are attacked, and the disease is threatening to prevent the civilisation of enormous tracts of territory.

The infecting agents are two parasites called the *Trypanosoma gambiense*, discovered in 1901 by our own graduate, Dr. Dutton, and *Trypanosoma rhodesiense*, discovered in 1910 by Professor Stephens

and Dr. Frantham, also of the Liverpool Tropical School. Other varieties of trypanosomes have practically exterminated the horse and all domestic animals in Central Africa.

The trypanosomes are introduced into man and the domestic animals by two varieties of biting insects—tsetse flies, viz., the *Glossina palpalis* and the *Glossina morsitans*. Now *Glossina palpalis* is limited to watercourses, but *Glossina morsitans* spreads uniformly over vast areas of country. In districts like Uganda, infected by *Glossina palpalis*, sleeping sickness is being very greatly diminished by the removal of the population from the banks of rivers and lakes; but in territories infected by *Glossina morsitans* the disease is still spreading.

A most remarkable discovery has just been made regarding the spread of sleeping sickness by two members of the Liverpool Tropical School, Drs. Yorke and Kinghorn. They found that a large proportion of the wild game in Equatorial Africa is infected with the identical varieties of trypanosomes which infect man and the domestic animals respectively.

The game, though apparently quite healthy, are veritable reservoirs of parasites constantly infecting the tsetse flies who feed upon them; and the tsetses in turn infect man.

The observations of Yorke and Kinghorn have already been confirmed. Two courses are theoretically possible, if these territories are to be rendered habitable to men, particularly white men, and the domestic animals; either the flies or the game must be removed from the region of human habitations.

Mr. Newstead, Professor of Entomology in the Tropical School, who has studied the question on the spot, tells me it is even more impossible to stamp out the tsetse fly in Africa than the house fly in England.

If, therefore, the infected regions are to be rendered habitable to man, and to his flocks and herds, there appears to be no alternative to driving away or destroying the game. This proposal is at present raising an outcry amongst some of the very men whose ancestors, also for the sake of civilisation, swept the wolf and the bear out of Britain.

Foot-and-Mouth Disease.

Foot-and-mouth disease has lately attracted great attention. It is exceedingly infectious, though not usually fatal, and spreads amongst cattle, sheep, and pigs. On rare occasions man is also infected, milk being the usual medium.

In the five years 1880 to 1884 inclusive, 750,000 cases were reported in Great Britain. In 1911, foot-and-mouth disease was apparently introduced into this country on no fewer than five separate occasions, and 3,000 cattle, pigs, and sheep were slaughtered.

The trade of Liverpool has been seriously hampered by foot-and-mouth disease in many ways. It has reduced the number of cattle dealt with in the Stanley market during the last six months of 1912 to 1,900 from 30,000 for the corresponding period, and sheep to 18,000 from 240,000. The Board of Agriculture's new regulations will probably result in the closure of that market and the erection of a new one in Birkenhead.

Owing to the disease, the import of live cattle into Liverpool from Argentine has been prohibited since 1903. According to evidence given at the Departmental Committee on Foot-and-Mouth Disease, the number of live cattle imported into Liverpool from abroad for slaughter has diminished from 565,139 to 219,501 in 1910, a diminution which is mainly due to the fact that most countries, other than the Argentine, are now consuming so many of their own cattle that they have few left for exportation.

On the other hand, the imports of dead meat over a similar period have increased from 5,778,357 cwts. to 7,557,374 cwts., and the bulk of this increase has been due to the imports from the Argentine, whose live cattle we prohibit from landing.

Now it is far better to import live than dead cattle; not only is a larger amount of shipping tonnage employed, but various other trades are supplied with raw material—as the hide trade, the boot and shoe trade, the fancy leather trade, the tallow, bone, glue, and gelatine trade, the hair, felt, and brush trade. In fact, it was stated at the Departmental Inquiry that the diminution in the number of live cattle imported into Liverpool during five years represents a loss in wages, paid in connection with these subsidiary industries, of over a million pounds sterling!

There is still an enormous surplus of live cattle in the Argentine which can be exported; 100,000 head were landed last year on the Continent, and if it were possible to remove the present embargo and import again into Liverpool, subsidiary trades would benefit enormously.

The British farmer would probably not lose money, because the export of dead meat from the Argentine would be correspondingly diminished.

Foot-and-mouth disease also causes serious loss in Ireland, which, according to a statement made in Parliament last month, amounted to between two and three million pounds. The cattle trade of Ireland is worth 20 millions a year.

We are still ignorant of the various factors governing the spread of this disease, which, according to the Chairman of the Inquiry, has produced the most serious situation in the agricultural world since 1868. Some assert that it may be conveyed by the birds of the air, by the wind, by straw, by eggs. We do not know!

The germ has never been seen; it is ultramicroscopic. (*a*) No method has yet been devised of preventive inoculation. The need of further research is great, and the benefits which might thereby result to the community at large are incalculable.

The Swine Fevers or Swine Plagues.

The whole question of the fevers in pigs, which cause enormous mortality, is still obscure. Recent research has demonstrated that what was originally believed to be one disease now comprises probably three, possibly more, viz.—swine erysipelas, produced by a minute bacillus; swine fever or hog cholera caused by an ultramicroscopic organism, though certain characteristic features of the disease are due to a secondary infection with *Bacillus suipestifer*; swine plague is thought by some to be swine fever combined with a secondary infection with a bacillus of the Pasturella group, by others it is classed as a separate disease. Swine fever is the most dangerous of all, and causes an annual loss in the United States of from 10 to 25 million dollars per annum.

A method of protective inoculation for swine erysipelas is stated to have reduced the death-rate in Hungary from 20 per cent. to about 1.6 per cent. as the result of 4,000,000 observations.

The year before last in Great Britain 2,466 outbreaks of swine fever occurred and over 30,000 animals were slaughtered.

One of the swine fevers at least occurs in man, viz. swine erysipelas, though it is rare.

Poliomyelitis.

I wish now to allude to two acute diseases of the brain and spinal cord—cerebro-spinal meningitis, or spotted fever, as it is sometimes called; and infantile palsy, or poliomyelitis, which occur in man and animals, but whether they are transmissible from one to the other is a matter of conjecture.

Poliomyelitis was first recognised about the middle of last century. Isolated cases are comparatively common among young children; it produces paralysis of one or more limbs, which may persist throughout life.

Recently, however, poliomyelitis has developed in epidemic form; 2,000 cases developed during the summer of 1907 in New York, while 154 with 34 deaths occurred the summer before last in the villages

(*a*) Within the last few months Siegel claims to have discovered the causal organism; but his claims have not yet been substantiated (Berlin, *Tierarztl. Wochenschr.* vol. xxviii., 1912).

and small towns of Devon and Cornwall, preceded by a smaller epidemic in Dorsetshire and the Midlands.

Some most interesting discoveries have just been made regarding this mysterious disease, entirely owing to the fact that it can be experimentally produced in monkeys. We now know that the germ or virus of poliomyelitis is small enough to pass through the minute pores of a porcelain filter; but far too small to be visible under the highest powers of the best German microscopes, magnifying four or five thousand times.

A living poison which passes through filters, and yet is invisible under the microscope, is called a filterable or ultramicroscopic virus. According to Flexner there are at least eighteen such diseases which are believed to be due to this class of minute living organisms. Three of them occur in man, viz.—yellow fever, dengue, and poliomyelitis. Dr. Seidelin, however, of the Liverpool Tropical School, has shown that in all probability the yellow fever virus is visible at one stage of its development.

Fourteen of these ultramicroscopic or filterable viruses occur in the domestic animals, and include foot-and-mouth disease, cattle plague, sheep pox, hog cholera, chicken plague, horse sickness, and perhaps canine distemper. Chicken-pox, smallpox, measles, and scarlet fever of man may also be due to filterable viruses. Some day science will be able to see these bodies, but the time is not yet.

Now it is significant that poliomyelitis is not a dirt disease like typhus, limited to crowded towns, but is common in the country and appears in spotlessly clean cottages. Again, diseases similar to poliomyelitis have recently been described in the domestic animals, horses, cows, pigs, chickens, and dogs. It is impossible apparently to infect chickens, dogs, or pigs with the virus of human poliomyelitis, which suggests they probably cannot convey the disease to man. But, so far as I am aware, no observations have been made upon horses or cattle or wild birds.

It has recently been suggested, on very good grounds, by a Swedish investigator, that food, possibly milk is a source of infection. In this connection it is important to remember that just before the discovery of the conveyance of Malta fever by milk was made by bacteriological research, two independent investigators, studying the problem on the spot from an epidemiological standpoint, came to the conclusion "that milk at least was not the cause."

Cerebro-spinal Meningitis.

There have been many epidemics of human cerebro-spinal meningitis or spotted fever recently. Nearly a thousand cases occurred in Glasgow six years ago, half of them died; however, it more often affects the country districts than cities (Osler). The disease is produced by a microbe called the meningococcus, and is only moderately infectious.

Now cerebro-spinal meningitis is described in the domestic animals, such as the cow, the dog, and the horse. Little is known about the cause of the disease in the horse, and still less in cattle, sheep, and dogs. The possibility that meningitis may sometimes arise from the meningococcus, as in man, is not even hinted at in the latest American text-book.

When we realise the discovery is quite new, that plague is spread by the rat, Mediterranean fever by the goat, sleeping sickness by the antelope, it is quite possible that poliomyelitis or cerebro-spinal fever may sometimes be conveyed by animals to man, especially as we are so profoundly ignorant of the organisms infecting birds and the smaller animals, as mice, guinea-pigs, rats, cats, etc. The need for further research is obvious.

Other Infective Diseases Communicable to Man.

I have said nothing of many other infectious diseases communicated by animals to man: as the hydatid and the acarus by dogs in Great Britain; of the various flukes and worms, like *Trichina* and *Tænia solium*, communicated by infected meat; of skin diseases, like favus and ringworm, communicated by the cat.

I have said nothing of certain types of acute food and milk poisoning, due to *Bacillus suipestifer*, *Bacillus enteritidis* of Gaertner, and probably *paratyphoid*, the first of which, according to the most recent information, is especially common in the intestines of healthy pigs, while the second occurs in rats and occasionally in cattle. In all probability the house fly sometimes carries these bacteria from animals to the food of man; this insect may shed from 2,000 to 350,000 microbes of all sorts while drowning in a fluid such as water or milk (Cox, Lewis, and Glynn).

I have said nothing of milk sickness, of Rocky Mountain fever, communicable to man by cattle; of Leishmania infantum, a disease of Tunisian children said to be indirectly communicated from dogs; or of rat-bite fever, due to an unknown virus which has recently been described for the first time in England. I have said nothing about psittacosis, a disease of birds—especially parrots—and occasionally communicated to man with fatal results. The point I wish to emphasise is this: the number of diseases recognised as communicable from animals to man is steadily increasing.

To be forewarned, however, is to be forearmed, and thanks largely to preventive medicine, the number of occasions upon which any given disease is communicated to man is, on the whole, steadily diminishing.

(*To be concluded.*)

OPERATING THEATRES.

HAMPSTEAD GENERAL HOSPITAL.

Intra-peritoneal Biliary Abscess Following Typhoid Fever.—Mr. Jackson Clarke operated on a woman, æt. 35, who had been sent to him by Sir John Broadbent on account of a painful swelling in the right umbilical and iliac regions. The patient had been sent to the Hampstead Hospital at the end of a mild attack of typhoid fever with a diagnosis of appendicitis. When the patient was under an anæsthetic a tense oval swelling was found in these regions. A median incision was made; on opening the peritoneum a thin, green fluid was evacuated containing a small quantity of thick pus in the last portion that came away. Further exploration was carried out to find the source of the abscess, but the liver, the gall-bladder and the stomach were hidden by masses of adhesions. The cæcum and the appendix were found to be quite normal. A large drainage tube was inserted and the wound closed except where the drainage tube came out.

Mr. Clarke said he thought that the abscess was probably due to a typhoid ulceration of the gall-bladder, the opening in the gall-bladder having subsequently healed. The patient made a good recovery, and at the end of three months is perfectly fit and well.

Operation for Abdominal Pain.—The same surgeon operated on a middle-aged woman, who had also been referred to him by Sir John Broadbent. The patient had complained for four months of almost continual pain in the lower part of the belly. The pain was constant with slight exacerbations. She had suffered from constipation during this time. The patient had lost her appetite and was losing flesh. Her appearance was suggestive of malignant disease of the large intestine. The abdomen was explored through a median incision, and everything was found normal except the appendix, which contained four small firm concretions and showed very slight congestion, and a ridge-like thickening of the peritoneum. The appendix was removed. Mr. Clarke remarked how much discomfort could arise from so slight a cause.

The patient made an uninterrupted recovery and has had no return of the pain.

MERCER'S HOSPITAL, DUBLIN.

Congenital Dislocation of the Hip.—Transplantation of a Rib.—Mr. W. I. de C. Wheeler, suc-

ceeding in forming a new rim to the acetabulum with a portion of transplanted rib in a child, æt. 4½, suffering from congenital dislocation of the left hip. Sutures of phospho-bronze wire were passed through the old rim of the badly-developed acetabulum before reduction of the head of the bone. After reduction a portion of rib about three inches long was rapidly removed from the left side and was placed in position in contact with bare cartilage along the upper and outer edge of the acetabulum. The phospho-bronze wire sutures were then secured over the transplant to hold it in position. The bloodless method had been tried without success. Crile's method of anæsthesia was employed.

TRANSACTIONS OF SOCIETIES.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, JANUARY 22ND, 1914.

The President, DR. E. W. HOPE, in the Chair.

DR. ADAM H. SIMPSON related a case of faulty metabolism which had resulted from panhysterectomy. There were marked changes in almost every joint, examination showed a deficiency in calcium in the blood, and the blood-pressure was low. The patient was treated with extract of pituitary gland and calcium lactate with marked success.

DR. BLAIR BELL and Sir JAMES BARR discussed the case.

Mr. R. W. MURRAY in a paper on the

GEOGRAPHICAL DISTRIBUTION OF APPENDICITIS

sought for an explanation of the change in type and the increase in virulence and frequency of this disease. He had been in correspondence with medical men all over the world, and the universal opinion was that natives were practically immune, so long as they continued to live on their ordinary simple diet. The more complex the diet, the more prone is an individual to appendicitis, and any excess in the saturated fats is an important predisposing factor. The increased frequency of appendicitis is the punishment of luxury. Our gastro-intestinal arrangements are unequal to the requirements of the 20th century.

Dr. HOPE pointed out that so far as this disease was concerned, the area of civilisation was coterminous with that of the surgeon.

Mr. PAUL referred to the bodies found in diverticula of the intestine composed of calcium soaps.

Dr. YOUNG, Mr. NEWBOLT, Dr. LOGAN, Mr. DUN, and Dr. STOOKES also joined in discussing the paper.

Dr. CLAUDE RUNDLE gave a short paper on

INDUCED PNEUMO-THORAX IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

He referred to the fact that Dr. James Carson, of Liverpool, was the pioneer and originator of this form of treatment, and had prophesied a great future for it. Dr. Rundle's communication was based on the results of the treatment in 21 cases with 250 injections without serious complications. He strongly advocated this form of treatment in cases of moderate severity where the involvement of the lung is partial and mainly unilateral. He considered the improvement is greater than that following on the administration of tuberculin. The difficulties met with are adhesions; subdiaphragmatic emphysema and ballooning of the scrotum; pyo-pneumo-thorax due to faulty *technique*; sudden death may occur; dyspnœa and distress. In his experience pain on inserting the needle is the greatest difficulty.

Dr. ADAMS reminded the meeting that Mr. Bickersteth was the surgeon who assisted Dr. James Carson in his first two cases. Dr. Adams had six patients under this treatment. He employed quinine and urea as a local anæsthetic.

Sir JAMES BARR saw no reason why air should not be used instead of nitrogen. He questioned the value of induced pneumo-thorax.

Dr. MCLELLAN, Dr. HICK, and Dr. JOHN HAY spoke.

ULSTER MEDICAL SOCIETY.

MEETING HELD JANUARY 22ND, 1914.

The President, MR. A. B. MITCHELL, in the Chair.

A DISCUSSION ON

SYPHILIS AND ITS TREATMENT BY SALVARSAN

was opened by Sir THOMAS MYLES, of Dublin. He went very fully into the various methods of treating this disease, and contended that although the introduction of "606" was a distinct advance in the treatment, it was not the certain cure so confidently expected by the profession and the lay public. Nevertheless, in some cases, especially in those destructive lesions of the throat and mouth in which the ordinary remedies often failed to effect any improvement, salvarsan acted like a charm. He had not found the drug of much benefit in those diseases of the nervous system that were usually attributed to syphilis, but it was very beneficial in the early stages of the disease. He discussed in detail the risks and contraindications to the use of salvarsan. With regard to the diagnosis, he thought that the finding of the spirillum in the primary sore marked a great advance, and enabled treatment to be confidently begun on vigorous lines. He had not the same confidence in the Wassermann test. It could not be obtained in the very earliest stages, and it was unnecessary when the disease was fully developed.

Dr. THOS. HOUSTON followed, and defended the Wassermann reaction as the most constant symptom of syphilis, and brought proof from a large number of cases from his own experience as to its value in the diagnosis of obscure cases. With regard to the *technique*, Dr. Houston preferred to cut down on the vein selected for injection of salvarsan. He did not use the drug for intramuscular injection, always using the intravenous method. He believed that three-fourths of the early cases were cured by salvarsan combined with mercurial treatment.

Sir JOHN BYERS thought the Wassermann reaction was of great value in the diagnosis of latent syphilis in women. He referred to the great havoc caused by syphilis in women and welcomed any method for its diagnosis in obscure affections in the female sex.

Professor SINCLAIR mentioned some complications attending the use of salvarsan in his own practice, and drew attention to the advisability of carefully selecting the cases for this method of treatment.

Dr. CALWELL preferred neo-salvarsan to the original preparation, and had had no untoward results following its use. He avoided the drug in cases of alcoholism. He had seen double optic neuritis, headache and aphasia disappear in one case after the injection of the drug.

Dr. RANKIN had seen wonderful results in destructive lesions. He used a fresh needle for each injection and sterilised it immediately before use. In this way the vein was easily entered. He had used salvarsan in some eye cases with no bad results.

Mr. S. T. IRWIN gave an account of the results in his own cases and mentioned the complications he had seen.

Dr. LOWRY, referring to the *technique*, considered that sharpness of the needle was most important. He considered that relapses were frequent after one dose. He drew attention to the rapidity with which the colour of the patient improved under this treatment.

Mr. O'DOHERTY advocated the use of the drug by the intra-muscular method, and had had very good results in this way.

Dr. ELIZABETH BELL said that syphilis was the chief cause of infantile mortality, and maintained the importance of sex education.

The PRESIDENT tendered the thanks of the Society to Sir Thomas Myles for his kindness in coming a long way in the busiest season of the year to take part in

the discussion, and called upon him to reply to the various criticisms.

Sir THOMAS MYLES replied shortly to the questions put by the various speakers, and the meeting, which was one of the best ever held in the history of the Society, terminated.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the eleventh meeting of the Royal Commission, held on January 19th, evidence was given by Lieut.-Col. Gibbard, R.A.M.C., head of the Rochester Row Royal Military Hospital. He said that the most important causes of the decrease of venereal diseases in the Army were the improved treatment and the instruction of the men by lectures and individual talks; other causes contributing to the reduction were greater temperance, the increased attractions of barracks and the greater encouragement given to sports and outdoor games. The problem of the prevention of the spread of venereal diseases in the civil population could best be attacked by providing early diagnosis and treatment, by enlightening the public regarding the disease by lectures and otherwise, and by promoting temperance. As syphilis was chiefly spread during the early stages of the disease, early diagnosis and treatment were of the greatest importance, especially now that the methods of diagnosis were so good and that by the use of salvarsan a patient was rendered non-infective in from 24 to 48 hours. For the provision of early diagnosis it was necessary that arrangements should be made whereby microscopic examinations and blood tests could be carried out free of charge to private practitioners or patients.

With regard to treatment, Col. Gibbard was of opinion that special hospitals for venereal diseases were not to be recommended; every general hospital should provide a certain number of beds for the treatment of the diseases, and these beds should be in general wards. An out-patients' department should also be organised, so as to give patients every facility for early diagnosis and treatment; and the department (which should not be called "Venereal") should be kept open at hours suitable to the working classes. Col. Gibbard thought that compulsory notification was most undesirable, as it would lead to concealment of the diseases.

On the subject of education respecting venereal diseases, he thought that there would be advantage in lectures being given at all large factories by selected medical men (or women where the employees were women), and that these lectures might perhaps be illustrated by kinemacolor photographs. At the lectures great stress should be laid on the importance of seeking medical advice on the first suspicion of the disease, and of not consulting chemists or quacks. The experience at Rochester Row had shown that much good might be done in this direction. The number of secondary cases among the men reporting sick at that hospital had been reduced until it was now only equal to the number of primary cases, whereas for the Army generally it had been found that for every soldier commencing treatment in the primary stage five began in the secondary stage. The importance of this reduction was illustrated in the results of the treatment of 62 consecutive cases of primary syphilis during the last 18 months, which have been under observation from periods varying from six to nine months from the completion of treatment. None of these cases have developed secondary symptoms, only one case relapsed, and that was probably a re-infection.

Col. Gibbard gave an account of the methods of treatment employed at Rochester Row and of the results obtained. The use of a combined treatment of mercury and salvarsan had effected a reduction in the average number of days in hospital on first admission from 42 to 23.2, while the percentage of relapses had fallen from 33 with mercury alone to 3.9 per cent with the combined treatment.

Questioned respecting some remarks which had been recently published regarding the dangers attending the use of salvarsan, Col. Gibbard said that all his experience had gone to show that, provided the medical man using it had acquired and knew thoroughly the *technique* and contra-indications, salvarsan could be safely used, and in conjunction with mercury was the most effective cure known. At Rochester Row they had had no deaths or ill-effects following its use, and they had given more than 3,000 intravenous salvarsan injections.

FRANCE.

Paris, Jan. 31st, 1914.

HÆMOPTYSIS.

THE modern treatment of hæmoptysis of consumptives consists in emetine, extract of the posterior lobe of the pituitary gland and hemato-serotherapy. Emetine, says Dr. Noel Fiessinger, was first employed by Flandin in the treatment of hæmoptysis. He remarked that the hæmorrhage ceased almost immediately, but it was necessary to repeat the injection (1 grain) for three or four days. Lesné and Renon treated by the same method several other cases with success, but they found that emetine was particularly indicated in congestive hæmoptysis without fever.

Pituitary extract was recommended by Rist. He made his experiments with pituitrine of Parke and Davis, representing two grains of the fresh gland per ten drops of liquid; he injected this dose into a vein at the bend of the elbow. Of twelve patients thus treated, complete arrest of the hæmorrhage was immediately obtained in ten cases, the injection had to be renewed in the two remainder. Léon Bernard confirmed the good effects of pituitrine, but noticed in one case certain symptoms that seemed very grave although transitory; pallor of the face, tendency to syncope and a painful sensation of anguish. Morichau-Beauchant observed similar accidents, and advised dilution of the drug in a little physiological serum.

Hæmato-serotherapy. Fresh serum possesses very strong coagulating properties. It is thus that the serum of the horse, the serum of Roux (diphtheria), the serum of Calmette (tetanos), have been employed in hæmoptysis, but, says Dr. Fiessinger, these serums expose the patient to seric and anaphylactic accidents of certain gravity in the adult and aged persons. In any case these serums should be proscribed in tuberculous patients. On the other hand if human blood is substituted for the blood of animals, provided that the blood is taken from a perfectly healthy person and as much as possible from a near relative of the patient, there is every guarantee of success.

Transfusion of blood is certainly very active, but too complicated for general practice. Recourse may be had to subcutaneous or intra-muscular injections of defibrinated blood. The blood taken from a vein of a healthy person is received into a bottle containing a certain quantity of glass beads where it is immediately defibrinated by agitation and injected subcutaneously at the dose of one ounce and a half. This method has been employed in some grave cases of hæmoptysis.

A more simple method is, perhaps, to receive the blood directly from the vein into a Roux syringe of the capacity of 20 cubic centimetres, and inject it into the muscles or under the skin. The injection can be repeated as often as necessary, but precaution should be taken to act quickly so as to avoid coagulation in the body of the syringe; the syringe should be warm and slightly coated with vaseline inside.

A third method consists in receiving into an aseptic recipient the blood which is left to coagulate; the serum thus exudated is injected beneath the skin or

into a vein. By this method any quantities of serum can be injected.

All these methods are simple and efficacious and are destined, according to Morichau-Beauchant, to a great future.

ERYSIPELAS.

Erysipelas belongs to that class of affections which recognise no specific treatment, and even many would say that any treatment succeeds (?) in erysipelas, while others go farther and affirm that this malady knows no treatment, that it follows its course (cycle) no matter what is done for it; these latter are, perhaps, not far wrong.

Be that as it may, something must be done and each practitioner has his own cut and dry treatment. The latest, to add to the already long list, is that recommended by Dr. Satre, of Grenoble, which is simplicity itself: Pyramidon. Given internally it abates the fever, arrests the extension of the inflammation (?) and improves generally the condition of the patient. As local application :—

Phenic acid crist., 15 grs.
Camphor, 15 grs.
Lanoline, 4 drs.
Vaseline, 4 drs.

GERMANY.

Berlin, Jan. 31st, 1914.

AT the Gynæcologische Gesellschaft, Hr. Stickel spoke on the

INFLUENCE OF THE OVARIES ON THE ACTIVITY OF THE UTERUS.

In testing the influence of the glands with internal secretion it was best to commence with the ovaries. Animals had now been examined that had been castrated and had then been given ovarian extract. Animals that had not been previously castrated were also given ovarian extract, and lastly animals that had been treated with Röntgen rays had been given the ovarian extract. In making the investigation, animals had had laparotomy performed under narcotics, this having no influence on the experiment in any way. One uterine cornu was then ligatured and its curves were marked out. It was then shown that the uterus, even without irritation, showed curves caused by its own anatomical contractions. When now ovarian extract was injected, the curves underwent a change accordingly as extract that strengthened contractions or weakened them was made use of. The injection could be given either into the muscle or subcutaneously. Only animals that had borne young were the subjects of experiment. All castrated animals had a flattened curve, as in the virginal animals, or none at all; all non-castrated ones had a characteristic curve, and for them extract of the corpus luteum and of the follicles was characteristic. The extract from animals that had been previously treated with Röntgen rays reacted differently. Castrated animals showed no oscillation whatever; on the contrary, even the excised uterus continued in movement. It must be, therefore, that by castration a contraction-checking hormone was liberated. In the same way there must be separate hormones for the other functions. It was noted that the corpus luteum was more resistent to the action of the X-rays than the follicles were. It was also to be observed that these results were very much in accord with those noted by Frank in regard to the human uterus.

Hr. Aschner said the normal secretion could be set up by the injections. The important question was: was the internal secretion called forth by the corpus luteum, the follicles, or the interstitial parenchyma? These glands were first made known ten years ago through the investigations of Limoud. These glands later, as far as concerned the human subject, were forced into the background by the corpora lutea. The higher the class of the animal, the more was this the case. In the new-born the interstitial substance was but scanty; it increased somewhat in the first few months of life, along with the follicular atresia, to finally become slight again at the period of puberty. It was of interest that the development advanced parallel with the number of young at a birth: in carnivorous animals that had numerous young at one birth the development of the interstitial substance was very strong. It was further determined that the interstitial substance was pushed aside by the corpora lutea. These, however, had no function; the dominating force was still the ovule.

Hr. Meyer suggested that the corpora lutea were devoid of function, as they were almost atrophied towards the termination of pregnancy.

At the Verein f. Innere Medizin und Kinderheilkund, Hr. Baerthlein discussed

THE ÆTIOLOGY OF INFANTILE DIARRHŒA.

The speaker had studied the flora associated with infantile diarrhœa at the bacteriological department of the Reichsgesundheitsamt. The greater part of the material came from the Baginsky Children's Hospital. In 70 cases of primary diarrhœa pathogenic germs were met with 38 times and 19 times bacteria of the dysenteric group, in 7 cases paratyphus B. bacilli, and in 12 pyocyaneus bacilli. In infants with dysenteric bacilli there was often blood in the evacuations and the mortality was high. Out of 13 cases studied with the special object, specific agglutinations were met with in 11. There was one death among the paratyphus cases. Amongst them the disease ran its course with symptoms of acute intoxication, but in a proportion of the cases the course was a more protracted and mild one. The cases with pyocyaneus bacilli appeared a moderately severe intestinal catarrh with diarrhœa and slight fever, with disturbance of the general health. A part showed severe intoxications.

Hr. Baginsky considered the observations to be well worth consideration. They showed that in the ætiology of infantile enteritis heat and alimentary influences were not the only ones that played a part, but that in many cases pathological germs were to be reckoned with.

AUSTRIA.

Vienna, Jan. 31st, 1914.

THE GENESIS OF SEX.

AT the eighty-fifth Congress of Deutscher Naturforscher und Aerzte, recently held in Vienna, the questions of the genesis and transformation of sex formed the subject of a very elaborate communication by Dr. E. Steinach, who started from the fundamental fact, which he regarded as thoroughly established, that in the germinal glands two kinds of glandular tissue are united, which have totally different functions. Some years ago he had himself succeeded by following out the process of transplantation in bringing to maturity the completely isolated internal secretory sexual glands in growing domestic animals—that is to say, completely free from the presence of all generative elements. The next task which he had undertaken was to determine whether the masculine and feminine glands were identical at the age of puberty, and whether then the growth and development of sexual character, according to the presence of one or the other glandular substance which distinguishes the period of puberty, thenceforward proceeded in the ripening organism. Previous researches on the lower animals had left the question of such possibilities still open. His extended series of researches on mammals had given a negative reply. The glandular structures which characterise the period of puberty exercise a strongly specific influence; they have the effect of calling forth the homologous, but not the heterologous, sexual characteristics. His researches had, however, yielded a further new result. The glands of the age of puberty have also the power of interpenetration of an individual of the opposite sex with their own specific powers, and thereby completely transforming the original sexual directive bias. This result is effected by two processes—by repression of the growth of certain heterologous secondary sexual characters, and by transformation of indifferent features into pronounced homologous secondary characteristics.

He examined first the process of feminisation—that

is to say, the transformation of males into individuals of completely feminine sexual character. The research was carried out on young rats and guinea-pigs. In order to provide a perfectly clear presentation of the result, the experiments were carried out on large litters, which grew up under the same conditions and environment; and, when the operations were over, the family relatives were again united: a normal male; a normal female; a male which had been castrated in earliest infancy; and, finally, one or more males on which the procedure of implantation of ovaries had been carried out after castration—also in earliest infancy. With such a series sufficient measurements could be made and comparisons instituted to which no objection could be raised. In the first place, then, it was definitely established by weighings, measurings, and Röntgen ray examinations, that by the influence of ovarian implantation, the growth of the skeleton—and with it that of the whole body—was directly limited. While the curve representing the growth of the castrated male almost coincided with that of his normal brother, the growth of those with implanted ovaries lagged far in the rear; so much so, indeed, that these gradually assumed the dimensions and individual characteristics of females. For example, the form of the skull, and the distinctive figure and delicacy of outline, the net result being that after the completion of their growth they are found to resemble their normal sisters to a much more striking degree than of their divergence from their normal brothers. The growth of the hair in the feminised male also displays a very marked modification in the direction of femininity: it presents a delicate and clinging hirsute cover. But the most impressive manifestation of the resulting feminisation is presented by the gradual transformation of the originally indifferent rudimentary form of the mammary glands and nipples into that of well-shaped, fully-formed feminine organs. The general impress of the feminised male is wholly that of the natural female type. Then not only the bodily sexual features, but even the psycho-sexual characteristics have also become feminine in type. Animals thus feminised have no masculine mettle or proneness to fight; they are rather cowardly and timorous, and present wholly typical feminine actions and movements and—what is most remarkable of all—they develop the characteristic feminine attractiveness for members of the opposite sex. Born males, they come to present the features of a purely feminine puberty. Especially do we find the mammary glands of such modified males not merely displaying the general appearance of those of the female, but proceeding to complete functional maturity. The hyperplastic glands actually secrete copiously a milk which is rich in fat and normal in its other qualities, and which can be readily pressed out, thus helping to make the functional deportment of those feminised males quite startling in character.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Late Dr. Jex-Blake's Estate.

An action has been raised in the Court of Session by the trustees of the late Dr. Jex-Blake in reference to the destiny of certain portions of her estate. In 1896 Lady Waldie Griffith gave Dr. Jex-Blake £500 for establishing a scholarship for students in the Edinburgh School of Medicine for Women. When the School was closed in 1900 Lady Griffith asked Dr. Jex-Blake to hold the fund in trust and use the income either for the benefit of medical women or for the Edinburgh Hospital for Women and Children, and in the event of the Medical School re-opening, to return the fund and income to their original purpose. If the School did not re-open during Dr. Jex Blake's life, the £500 was to be transferred to the trustees of the hospital. The School of Medicine has never been re-opened, but another was established in 1890 which had no connection with that of Dr. Jex-Blake, and which was disapproved by her. The Court is now petitioned to sanction a scheme whereby pecuniary assistance will be rendered to young women doctors pursuing their studies at the hospital. The Dean and Managers of the Edinburgh School of Medicine for Women founded in 1908 have lodged answers to the petition. (It should be explained that this is really the third women's medical school which has existed in Edinburgh. The first was Dr. Jex-Blake's, which closed shortly after a rival school was started. This second, rival, school died about 1907, when its premises were sold over its head, and when the University refused to allow the students to attend University classes. The third, present, school was started by the lecturers in the previous one, who undertook the management and provided new accommodation.) The authorities of the new school submit that the fund would be disposed of in the manner most closely resembling its primary purpose if it were employed in establishing a scholarship at the present school. The University Court would be willing to control the fund. Dr. Jex-Blake's trustees are also petitioning that the Court should sanction the administration of a fund of somewhere about £1,650 by the University of Glasgow for Queen Margaret's College. The money was left to Dr. Jex-Blake to assist in the education of students, especially natives of India. When the School closed in 1908 Dr. Jex-Blake transferred the fund to Glasgow. The Dean of the Edinburgh School urges that the money, also, should be returned to the Edinburgh School, as being in the best position to carry out the original wishes of the testator.

The Insurance Act.

A conference under the Faculty of Insurance was held in Edinburgh on the 29th ult. The Faculty of Insurance is a new body founded to bring together all persons and organisations interested in the Act. Dr. McVail, medical member of the Insurance Commission, said that though there were still difficulties requiring solution, the medical profession were much more satisfied than had seemed likely a year ago. Their anxieties were now alleviated, and they were coming to realise their responsibilities under the Act. A little time was necessary to allow the profession to shake down to its new surroundings, and he had faith in the doctors of Scotland that they would do their best by the Act. In discussing the doctors, they should try to believe they were doing their best.

Mr. Appleton, Secretary of the General Federation of Trade Unions, said their difficulties in England with regard to medical benefit were greater than in Scotland. They suffered because of the imperfect diagnoses and ambiguous language on medical certificates which had to be read by secretaries of friendly societies who had no medical training. The greatest difficulty was that in England medical men did not realise that they had not only to certify a particular form of illness, but also incapacity. Thousands of certificates were given in certifying incapacity, while the patients were really quite capable of work. Doctors stated that they were not there to do the work of the Society, and the latter was responsible for deciding whether the patient was incapable. His reply was that they paid for a certificate of illness and incapacity, and that they ought to get it. They had had to appoint and pay trained inspectors to visit members in order that they should not become victims of the dishonesty of a member and the negligence of a doctor. He also referred to complaints from nearly every quarter concerning the treatment they were receiving from medical men, and from the continuance of the high rate of sickness they had come to the conclusion that there was negligence as to treatment on the part of the profession. He thought that the negligence was very largely due to the fact that some doctors had far too many patients on their lists. His own feeling was very strongly in favour of a State medical service, with rigid inquiries into all cases of excessive sickness.

After some further discussion, a member of the Edinburgh Insurance Committee said that there had been only two meetings of the Complaints Committee, and that, he thought, was enough to dispose of any idea of general complaint, so far as Edinburgh was concerned.

GLASGOW EYE INFIRMARY.

THE annual report, just issued, of Glasgow Eye Infirmary shows, as in the cases of the Victoria and Western Infirmaries, an increase in contributions from workmen (or at least from public works), notwithstanding the Insurance Act. On the other hand, the annual subscriptions show a considerable diminution, whether or not this be due to the incidence of insurance contributions upon employers. The number of in-patients in the Infirmary during 1913 was 1,528; the average daily number being 79.48, as against 97.7 last year. While the daily average may not show that the capacity of the Infirmary was fully taxed, there are periods, the report states, during every year when the number of unoccupied beds falls short of the number of patients seeking admission to the institution, and a waiting list becomes necessary. The financial statement shows that the ordinary income amounted to £4,578, as compared with £4,533 in 1912.

ROYAL HOSPITAL FOR SICK CHILDREN.

The directors of the Royal Hospital for Sick Children state that the new hospital at Yorkhill is rapidly nearing completion, and that it should be ready for occupancy in summer. They state in their report that, although the subscriptions to the building fund received during the year 1913 reached a substantial total, a sum of nearly £16,000 is still required. The number of patients treated in the wards in 1913 was 1,315, as compared with 1,208 in 1912.

STIRLING INSURANCE COMMITTEE.

Stirling Burgh Insurance Committee is experiencing some financial embarrassment in its administration of sanatorium benefit. A sub-committee has reported that in view of the shortage of funds, they had met with the Public Health Committee of Stirling Town Council regarding a suggested temporary arrangement for treating consumptive insured persons and their dependants, until the permanent sanatorium scheme for Stirlingshire and Clackmannanshire comes into operation. The Joint Committee came to the conclusion that the Insurance Committee might deal with the applications of insured persons for sanatorium benefit by recommending only early cases, or cases likely to benefit permanently; that other cases might be dealt with, so far as the funds of the Committee would permit, by recommending treatment other than institutional treatment; and that the Insurance Committee might report to the Town Council from time to time the cases which they were unable to treat through lack of funds, and especially designate those that were of an urgent nature. The Town Council could treat those cases and claim one-half of their expenditure from the Treasury. The Insurance Committee adopted the recommendation.

BELFAST.

FORSTER GREEN HOSPITAL.

THE eighteenth annual meeting in connection with the Forster Green Hospital for Consumption and Chest Diseases was held on the 27th ult. Dr. Thomas Houston submitted the report of the honorary medical staff of the work done in the sanatorium and dispensary for the year 1913. On January 1st, 1913, there were 51 patients in the Sanatorium, and 277 were admitted during 1913, thus making a total of 328 treated in the past year. These figures show a slight increase on the numbers for 1912. During the past six months the hospital has been full, and patients have frequently to wait for a short period before they can be admitted. The following estimate of the progress made by the 277 patients admitted during the year has been prepared by Dr. Williams, the Resident Physician:—On admission 110 cases were classed as incipient, 149 as advanced, and 18 as far advanced. Of these 207 were improved by their treatment in the Sanatorium, and in a number the disease seemed to be arrested. Sixteen patients remained less than one week, and 11 remained over 20 weeks. The average stay in hospital was 10.81 weeks. During the year six cases died in hospital. In the out-patient department 1,012 new cases presented themselves—742 for advice and treatment in the extern, and 270 for examination with a view to admission to the Sanatorium. The attendance of old cases amounted to 3,581, making a total of 4,596 attendances during the year, or since the foundation 90,914. These figures are the highest that have yet been recorded. Since 1908, the year in which the new arrangements for the extern were made, the new cases have increased from 425 to 1,012, and the attendance of old cases from 924 to 3,584.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE VALUE OF HELIOTHERAPY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been directed to a very interesting editorial comment in the MEDICAL PRESS AND CIRCULAR of January 14th (page 28) on this subject. I regret to note that nowadays there appears to be a tendency to belittle British medicine. I practised heliotherapy before M. Rolier was qualified. It is quite a mistake to think that there is too little sun to practise the cure in the British Isles, because there are numerous localities where there is a fair amount of sunshine all the year round. It is our competitors in other lands who write pessimistic accounts on this subject. Of course, I do not wish to deny that at high altitudes and with a clear sky the actinic rays of the sun are more powerful and can be more easily harnessed, but I defy anyone to bring forward better cases of cures than my own.

I may add that heliotherapy, although of great curative value, is insufficient to do away with the treatment by drugs and diet; it is the combined treatment that does so much good in tuberculosis and enlarged joints of a rheumatic or toxic origin. There is really nothing new about the treatment by heliotherapy, for Roman physicians practised it.

I am, Sir, yours truly,

London. THOMAS DUTTON, M.D., M.R.C.P.

January 27th, 1914.

WHAT IS THE SPECIFIC FOR SYPHILIS?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—How do we stand with regard to the new specifics for syphilis, and even the new infallible tests?

Mr. McDonagh, the chief authority, I suppose, in these parts, tells us in your pages:—

"It is doubtful whether our interpretation of the Wassermann reaction is correct. I have been able to make it positive or negative at will."

"A laboratory diagnosis can never be more than mere confirmatory evidence of a clinical diagnosis."

"The lesions of syphilis may vanish without treatment due to the ferment action of the serum."

"Syphilis is cured, not by the treatment we give, but by the resistance of the host, which we assist by treatment."

Finally, in last week's *B.M.J.*, "It has not been proved that any arsenical compound—not even salvarsan—will cure syphilis."

Quid est veritas?

I am, Sir, yours truly,

Dublin. J. C. MCWALTER, M.D.

January 21st, 1914.

MEDICAL NEWS & PASS LISTS.

The National Medical Union and Unqualified Practice.

THE council of the National Medical Union has unanimously passed the following resolution with reference to the Insurance Commissioners' new regulation, recently announced, as to the treatment of insured persons by unqualified practitioners:—

"That this council protests against the regulation 44 (2) of the National Insurance Commissioners, containing provisions which seek to legalise the treatment

of those insured under the Act by persons who are not duly qualified practitioners, and instructs the secretaries to bring the terms of the regulation to the notice of the General Medical Council and to request them to take action."

Professor Ehrlich Honoured in Paris.

A magnificent reception was accorded to Geheim-Rat Professor Paul Ehrlich on Monday last in Paris at the Broca Hospital. Dr. Jeanselme, one of the first medical men in France to whom Professor Ehrlich submitted his new specific, salvarsan, delivered a striking address in praise of the discoverer and his work. In reply, Professor Ehrlich stated that he owed much of his success to the support of the French medical men, and that at present he was directing a research towards the combination of salvarsan with preparations of copper or gold.

The Royal College of Physicians of London.

At a meeting of the *comitia* held last week, it was announced that Sir R. Douglas Powell will deliver the Harveian Oration on St. Luke's Day; Dr. Nestor Tirard the Bradshaw Lecture in November; and that Dr. Edgar Leigh Collis, M.B. Oxford, H.M. Medical Inspector of Factories, had been appointed by the Council to delived the Milroy Lectures in 1915.

Dr. Shufflebotham will give the Milroy Lectures on February 19th, 24th and 26th, and on March 3rd and 5th, the subject being "The Hygienic Aspect of the Coal-mining Industry in the United Kingdom"; Dr. M. A. Cassidy the Gorlstonian Lectures on "Rheumatoid Arthritis," on March 10th, 12th, and 17th; Dr. J. A. Ormerod the Lumleian Lectures on "Some Modern Theories Concerning Hysteria," on the 19th, 24th, and 26th of the same month; and Dr. F. Gowland Hopkins the Oliver-Sharpey Lectures on March 31st and April 2nd.

The following have been admissed Members of the College:—J. M. Fortescue-Brickdale, M.D.Oxford, Guy's, of Bristol; A. C. Ingram, M.D.Camb., L.R.C.P. and M.R.C.S., Capt. I.M.S., Char. Cross; S. G. Luker, M.D.Camb., Lond. and Freiburg; G. H. Monrad-Krohn, M.B.Christiania, L.R.C.P., M.R.C.S.; J. H. Newmarch, L.R.C.P., M.R.C.S., St. George's and Munich; D. W. Patterson, M.B.Durh; of Newcastle-on-Tyne; J. W. Trevan, M.B.Lond., L.R.C.P., M.R.C.S., St. Bartholomew's; G. E. S. Ward, M.D. Lond, Middlesex; R. C. Wingfield, M.B.Oxford, St. Thomas's.

The following candidates having conformed to the by-laws and regulations, and passed the required examinations, had licences to practise physic granted to them at this meeting:—A. D. Anderson, E. B. Argles, H. A. Ash, G. Aspinall-Stivala, C. H. B. Avarne, E. R. Bailey, A. C. Ballance, F. D. Bana, F. M. Barnes, W. C. P. Barrett, M. H. Barton, F. P. Bennett, A. H. F. Bizarro, P. R. Boswell, A. Bouchage, F. C. S. Broome, D. A. Carmichael, H. Chand, S. F. Chellappah, T. L. Chiplonkar, E. L. Christoffelsz, W. H. Cornelius, F. H. L. Cnnningham, J. C. Davies, L. R. G. de Glanville, R. M. de Mowbray, C. K. G. Dick, K. J. Dikshit, R. H. Dix, P. Dvorkovitz, G. D. East, M. L. Bakry, R. Errington, A. P. Ford, A. N. Garrod, N. Gray, F. H. Guppy, H. Gwynne-Jones, W. R. H. Heddy, D. A. Henderson, C. L. Herklots. E. S. W. Hirsch, G. A. Hodgson, T. J. H. Hoskin, N. S. Jatar, D. W. Jones, G. L. Jones, T. A. Jones, W. M. Khan, J. G. L'Etang, G. H. S. Letchworth, R. J. McN. Love, N. P. L. Lumb, R. G. Lyster, K. H. McMillan, D. G. McRae, J. E. Margnat, F. D. Marsh, E. H. Marshall, W. H. Marshall, J. H. Mather, R. K. Merson, G. C. Metcalfe, L. E. Napier, H. G. Oliver, W. J. Paramore, C. F. Pedley, R. A. Preston, J. L. Priston, G. B. Pritchard, W. R. Pryn, H. J. Rawson, S. A. Riddett, G. D. Robertson, P. H. C. C. Schmidt, A. G. Shera, C. Sherris, R. Silcock, F. G. A. Smyth, T. R. Snelling, A. H. Southam, M. T. W. Steedman, C. K. Sylvester, J. B. Thackeray, M. C. Thavara, F. Tooth, H. Topham, T. R. Trounce, D. S. Twigg, J. B. Vaidya, R. E. S. Waddington, G. H. D. Webb, F. E. Weerasooria, J. R. White, S. B. White, L. C. Wilkinson, J. F. W. Wyer.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons to the following:—C. N. Atlee, L.R.C.P., M.R.C.S., W. J. E. Bell, M.B., Ch.B., *R. L. H. Davy, M.B., B.S.Lond., L.S.A., C. L. Dunn, Capt. I.M.S., L.R.C.P. and S.Edin., L.F.P. and S.Glasg., *Irene D. Eaton, M.B., B.S. Lond., *M. T. Féré, L.R.C.P. and S.Edin., L.F.P. and S.Glasg., A. B. Fry, Major I.M.S., M.D.Lond., L.R.C.P., M.R.C.S., C. J. Galbraith, M.B., B.S.Lond., L.R.C.P., M.R.C.S., M.K. Kapur, L.M.S., N. B. Kolsavala, L.M. and S., N. Low, Capt. Roy. Army Med. Corps, L.R.C.P., M.R.C.S., D. McIntyre, M.B., Ch.B.Glasg., *M. E. Middleton, M.B., B.S.Lond., A. H. Moore, M.B., B.C.Camb., C. C. Morrell, L.R.C.S., L.R.C.P.Edin., L.F. and P.Glasg., W. W. Pratt, M.B., B.S.Lond., L.R.C.P., M.R.C.S., K. N. Rau, M.B., C.M.Madras, R. O. Sibley, M.D.Lond., L.R.C.P., M.R.C.S., C. L. Sutherland M.B., Ch.B., J. M. Todesco, L.R.C.P., M.R.C.S., F. E. Wilson, Capt. I.M.S., M.B., C.H.B.Edin., J. H. Wood, M.B., B.S.Durh., L.R.C.P., M.R.C.S., J. H. Writer, L.M.S. Bombay. *Under the Medical Act, 1876.

Commissions in the R.A.M.C.

The War Office issued last week the following list of successful candidates for commissions in the Royal Army Medical Corps at the competition held in London in January, 1914, for which 42 candidates entered:—*T. O. Thompson, B.A., M.B., B.Ch.Oxford, 601.5; S. J. Linzell, M.B., Ch.B.Edin., 584.5; *S. R. Shore, B.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond., 580; *J. G. Gill, M.B., Ch.B.Edin., 565.5; *J. W. C. Stubbs, B.A., M.B., B.Ch., B.A.O.Dub., 557.5; *S. M. Hattersley, B.A., M.B.Cantab., M.R.C.S.Eng., L.R.C.P.Lond., 556; *D. W. Rintoul, M.B., B.S.St. And., 552; A. Watson, M.B., Ch.B., D.P.H., D.T.M.Edin., 547.5; *N. V. Lothian, B.Sc., M.B., B.Ch.Glasg., 545; *T. F. P. Breen, B.A., M.B., B.Ch., B.A.O.Dub., 540.5; J. F. G. Gwynne, M.B., Ch.B.Sheffield, 533; A. J. A. Menzies, M.A., M.B., Ch.B.Edin., 529.

*These gentlemen, being in possession of certificates obtained in the Officers Training Corps, were awarded service marks under Paragraph 71 of the Regulations for the Officers Training Corps.

Indian Medical Service.

The competitive examination for commissions in His Majesty's Indian Medical Service was held from January 26th to 31st at the Royal Army Medical College and the Medical Examination Hall for twelve vacancies. All the candidates reached the number of marks required to qualify. The following are the names of the successful candidates, with marks obtained out of an aggregate of 5,100:—George H. Mahoney, B.Sc., M.B., B.Ch., B.A.O., Nat. Univ., Ireland, University College, Cork, 3,656; William R. Stewart, M.B., Ch.B.Edin., Edinburgh University, 3,400; Gordon Covell, M.B., B.S.Lond., Guy's Hospital, 3,375; John G. O. Moses, M.B., Ch.B.Edin., Edinburgh University, 3,281; Koty V. R. Rao, L.R.C.P., M.R.C.S., London Hospital, 3,241; Hari Chand, L.M.S.Punjab, L.R.C.P., M.R.C.S., Lahore Medical College and Charing Cross Hospital, 3,208; Jacob W. van Reenen, M.B., Ch.B.Edin., Edinburgh University, 3,163; Venkata S. Mahadevan, L.M. and S.Madras, L.R.C.P. and S.Edin, L.F.P. and S.Glasg., Madras and Royal Infirmary, Edinburgh, 3,156; Alured C. L. O'S. Bilderbeck, B.A.Cantab., M.B., B.S.Lond., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital, 3,142; Maurice J. Roche, M.B., B.Ch., B.A.O., National University, Ireland, Queen's College, Cork, 3,119; Basil F. Beatson, L.R.C.P., M.R.C.S., S. Mary's Hospital, 3,112; Nehchal D. Puri, M.B., B.S.Punjab, Lahore Medical College, 3,088; Prabodh Chandra Roy, M.B.Calcutta, 3,044; Monindranath Das, M.B.Calcutta, L.R.C.P., M.R.C.S., 3,009; Jagannath Balkrishna Vaidya, L.M. and S.Bombay, L.R.C.P., M.R.C.S., 2,983; Joseph Martin Reeves Hennessy, L.R.C.P. and S.Edin., L.F.P. and S.Glasg., 2,823; William Mawhood Lupton, B.A.Cantab, L.R.C.P., M.R.C.S., 2,815; Alfred Glen Cowper, L.R.C.P. and S.Edin., L.F.P. and S.Glasg., 2,808; Hubert Horan Brown, B.A., B.C.Cantab, L.R.C.P., M.R.C.S., 2,757; Charles Henry Niel Baker, L.R.C.P. and S.Edin., L.F.P and S.Glasg., 2,716.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

THE MEDICAL REGISTER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On January 29th a circular of inquiry as to the accuracy of his address on the *Medical Register* was sent to every medical practitioner between the letters A and L, both inclusive. Any practitioner who does not receive one of these circulars in course of post should communicate with me immediately, in order that there may be no risk of his name being taken off the *Register* because he cannot be communicated with.

Yours faithfully,
NORMAN C. KING,
Registrar.

DR. F. S. (Herts).—In order to comply with the provisions of the Inebriates Act, it is necessary, except in the case of a voluntary resident, that the request for reception be signed by the patient before a Justice of the Peace, coupled with a statutory declaration signed by two persons who can testify that the applicant is an inebriate within the meaning of the Act of 1879 as amended by the Act of 1898.

M. B. (London, E.).—An insatiable craving for food occurs as a symptom of many physical disorders apart from diabetes. It is most frequently seen in connection with neurotic or hysterical conditions, and also in certain types of cerebral disease.

FAIR PLAY (Wimbledon).—The subject is dealt with in our editorial columns. As matters stand at present, the unqualified practitioner stands a good chance of reaping a rich harvest among all classes.

P. M (Bowes Park).—The symptoms resemble those of mushroom poisoning. One-sixtieth of a grain of atropin hypodermically is quite a safe remedy for an adult thus attacked.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 4TH

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8 p.m.: Cases by Mr. Frank Moxon. 8.30 p.m.: Discussion on the Use of Salvarsan in Ophthalmic Practice (opened by Mr. W. Lang, Lt.-Col. Gibbard, R.A.M.C., and Mr. S. H. Browning). Members desiring to take part in the discussion are asked to notify the Junior Hon. Secretary.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lectures: Prof. H. Gilford: Infantilism.

THURSDAY, FEBRUARY 5TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m.:—Specimens by Dr. Herbert Spencer. Short Communications by Dr. T. G. Stevens, Mr. Gordon Ley and Mr. J. Preston Maxwell (China). Paper: Prof. H. Briggs and Dr. R. A. Hendry (Liverpool): Uncontrollable Uterine Hæmorrhage: a Report on 104 Bleeding Uteri after Hysterectomy.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham).—4.15 p.m.: Clinical Meeting.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Dockrell: Fungous Diseases of the Hair—I., Hyphogenic Sycosis; II., Tinea.

FRIDAY, FEBRUARY 6TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4 p.m.: The President (Dr. D. R. Paterson): Two Cases of Intra-nasal Dacryo-cystotomy for Lachrymal Disease. Cases and Specimens by Mr. E. B. Waggett, Mr. Lawson Whale, Mr. Geo. Wilkinson (Sheffield), Mr. Harold Kisch, Mr. J. F. O'Malley, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Discussion: On Intratracheal Ether (opened by Mr. R. E. Kelly and Mr. H. E. G. Boyle). Dr. F. E. Shipway and Mr. M. S. Pembrey: Observations upon Respiration and Circulation during Intratracheal Anæsthesia.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8.30 p.m.: Pathological Evening.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lecture: Prof. E. W. H. Groves: Experimental Production and Treatment of Fractures in Lower Animals.

MONDAY, FEBRUARY 9TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion: The Value of the Operation of Decompression of the Brain in Cases of Inter-cranial Hæmorrhage, the Outcome either of Accident or Disease, to be introduced by Mr. L. B. Rawling and Dr. Hamill, followed by Mr. C. A. Ballance, Mr. Percy Sargent, Dr. Judson Bury, and others.

TUESDAY, FEBRUARY 10TH

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY).—5.30 p.m.: Papers: Mr. W. G. Spencer: The Thyreoglossal Tract. Mr. H. J. Curtis: The Most Efficient Method of Drainage in Septic Peritonitis.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY).—5.30 p.m.: Members of this Section are invited to attend the Meeting of the Section of Surgery.

Appointments.

COOPER, GEO., B.A., M.D.Belf., House Physician at the National Hospital for the Paralysed and Epileptic, Queen Square.

DOBSON, J. F., M.S.Lond., F.R.C.S.Eng., External Examiner in Surgery in the University of Durham.

FREW, ROBERT S., M.D.Edin., M.R.C.P.Lond., Assistant Physician for Diseases of Children to King's College Hospital.

HOPE, CHARLES W. M., M.D., B.S.Durh., F.R.C.S.Eng., Assistant Surgeon to the Throat Department at King's College Hospital.

TURNER, F. DOUGLAS, M.B.Lond., Medical Superintendent of the Royal Eastern Counties Institution for Imbeciles, Colchester.

WHITE, ARTHUR, M.R.C.S., L.R.C.P.Lond., L.D.S.Eng., Dental Surgeon to the Belgrave Hospital for Children, London.

Vacancies.

County Asylum, Shrewsbury.—Senior Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, laundry, fuel, light, and attendance. Applications to the Medical Superintendent.

County Asylum, Dorchester.—Assistant Medical Officer. Salary £250 per annum, with board, lodging, etc. Applications to the Medical Superintendent.

Borough Hospital, Birkenhead.—Senior House Surgeon. Salary £120 per annum, with board and laundry. Applications to the Secretary.

Borough Hospital, Birkenhead.—Junior House Surgeon. Salary £100 per annum, with board and laundry. Applications to the Secretary.

Warwick County Asylum, Hatton, near Warwick.—Second Assistant Medical Officer. Salary £225, with full board, lodging, and laundry. Applications to Dr. Miller, Medical Superintendent.

Births.

BILLINGHURST.—On Feb. 1st, to Dr. and Mrs. W. B. Billinghurst, of Shanghai, a daughter.

COMYN.—On Jan. 30th, at White House, Hythe, Kent, the wife of A. F. Comyn, M.B., Camb., a son.

EVE.—On Jan. 28th, to Dr. and Mrs. Frank Eve, 14 Albion Street, Hull, a son.

FORD.—On Jan. 31st, at Rushmere, Wimbledon Common, S.W., the wife of Frank C. Ford, M.B., a daughter.

HARVEY.—On Jan. 30th, at 199 Southampton Street, London, S.E., to Dr. and Mrs. Claude Harvey, a son.

HAWKINS.—On Jan. 28th, at 56 Portland Place, to Dr. and Mrs. Hawkins, a daughter.

WOOLLEY.—On Feb. 1st, at 15 Lower Camden, Chislehurst, the wife of Victor James Woolley, M.D. (King's College, Cambridge), a daughter.

Marriages.

ATKINSON—TREGASKES.—On Tuesday, the 27th Jan., at St. Mark's, Farnborough, Charles Henry Fairbank Atkinson, Physician and Surgeon, of St. Tudy, Cornwall, son of the late John Harrison Atkinson, Esq., of 50 St. Charles Square, W., to Maude Marion, daughter of the late Nicholas Henry Tregaskes, Esq., of Bude, Cornwall.

CAMPBELL—WALLACE.—On the 29th inst., at Melton Ross, John J. W. Campbell, L.R.C.P. and S., Castleford, Yorks, to Eva, daughter of the Rev. J. D. C. and Mrs. Wallace, of Melton Ross, Lincolnshire, and granddaughter of the late Major-General Wallace, of the 20th Madras Regiment.

CARTER—BELOE.—On the 26th Jan., at the Cathedral, Calcutta, Humphrey Gilbert Carter, M.B., Economic Botanist to the Botanical Survey of India, to Dorine Nanette, youngest daughter of Mr. and Mrs. Beloe, Canynge Road, Clifton, Bristol.

DOBRASHIAN—HERBERT.—On the 29th Jan., at the Friends' Meeting House, St. Martin's Lane, Rowland Dobrashian, M.B., B.Sc., etc., son of Dr. G. Dobrashian, of Greenhill Road, Harlesden, to Muriel, only daughter of Sir Jesse and Lady Herbert, of Sudbury Hill, Harrow.

Deaths.

DE RENZI.—On Jan. 22nd, at Christchurch, New Zealand, following an operation, Arthur Castriot, M.R.C.S., L.S.A., D.P.H., fourth son of the late Rev. Geo. D. De Renzi, B.A., late Chaplain H.M. Prison, Wandsworth, aged 49.

GUNTHER.—On Feb. 1st, at 2 Lichfield Road, Kew Gardens, Albert Gunther, M.A., M.D., F.R.S., in his 84th year.

HODGE.—On Jan. 27th, at Rothwell Road, Gosforth, Albert Ernest Hodge, M.B., B.S.Durh., aged 36.

RAWLINS.—On Jan. 29th, at 59 Greencroft Gardens, Hampstead, William Peter Rawlins, M.D., late of Gordon House, Highgate Road, and Hayward's Heath, Sussex, in his 74th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, FEBRUARY 11, 1914. No. 6.

NOTES AND COMMENTS.

Lawyers on the Panel.

IN his speech on February 6th, Mr. Lloyd George stated that during the past year an average of £230 per annum had been paid to each panel doctor. That sum, however, is not all fresh income derived from the Insurance Act. In order to form a just estimate, the payments formerly derived from clubs must be deducted. After his announcement of the £230 average, the Chancellor raised a laugh by remarking, "How the solicitors would have been delighted to get it!" The parallel thus playfully suggested merits a little further consideration. Let us assume, for the moment, that the State decided to engage a portion—say, nine-tenths—of the solicitors of the United Kingdom to minister to the legal wants of the labouring classes on terms roughly corresponding with those of medical benefit under the National Insurance Act. First of all the lawyers would have to organise a vast system of voluntary legal charities, where advice and legal service would be given to, say, two-thirds, of the community or whatever number corresponds with the present hospital class.

Tit for Tat.

THESE legal dispensaries and hospitals, so to call them, would be served by qualified solicitors who would give their services free, gratis and for nothing, just as hospital surgeons, physicians and specialists do under present circumstances. Then the panel solicitor, as in duty bound, would be at the beck and call of his one or two thousand or more clients on his panel. In addition to working ten or twelve hours a day for his £230 a year, he would be liable to be called away long distances to give advice and also to do an uncertain amount of night-work. His gross income would be made up by private practice in the intervals of panel work. If this picture pleases Mr. Lloyd George, it may be elaborated with little trouble. A State legal insurance service would be almost as great a boon for the labouring classes as a purely medical one. The Chancellor may be thanked for calling attention to an interesting point in connection with his own profession. Meanwhile the unpaid surgeons, physicians and specialists of our vast hospital service are attending crowds of insured persons, and are thus contributing largely by their unpaid skill and labour to the funds from which Mr. Lloyd George draws his boasted average of £230 per panel doctor. Why should general practitioners be paid and hospital staffs exploited? Why should not the lawyers be amerced in a National Insurance system?

Sex Teaching Banned.

A CURIOUS situation has arisen in the little town of Dronfield in regard to the nature of certain eugenic instruction imparted to the scholars of the Council school by the headmistress. From the newspaper reports it appears that exception has been taken by the school managers to any kind of sex teaching being given, and, in their disapproval, they went so far as to ask the Derbyshire Education Committee to hold an inquiry into the facts and to request the resignation of the headmistress. A public meeting was held last week protesting against the special instruction and supporting the local managers in their action. The Derbyshire Education Committee, however, has not seen fit to comply with the request of the managers—*hinc illæ lachrymæ*. It is reported that one speaker said that "they did not want children at eleven years of age to know as much as midwives." Meanwhile, the children are to be kept away from school until the matter is settled. We do not know the precise nature of the instruction in sex hygiene which this no doubt well-intentioned lady has sought to impart to her young charges, nor why the wrath of the authorities has been so deeply stirred. Instruction in the laws of sex needs to be very carefully given to children, and it is a question whether it need be imparted at all, except to senior scholars. A study of botany and zoology is the best preparation for the reception of wisely selected truths regarding sexual science as applied to human beings.

The Rural Cottage.

THE foundation of all national health lies in the housing of the poor, both in town and in country. Good houses are essential to good health, while bad houses spoil the natural fitness of mind and body that should be the birthright of all mankind. In rural districts the shortage of cottages plays an important part in the depopulation of the countryside that constitutes a standing reproach to modern social life. One great obstacle in the way of reform is the difficulty of building cottages that may be let at a profit. The average agricultural labourer cannot pay more than half-a-crown or three shillings a week rent. Recently an architect has offered to build a roomy convenient cottage of fair size for £120, a cost that would permit of its being let at half-a-crown a week and at the same time secure a small interest on outlay. One point may be submitted to housing reformers—namely, the absurd building restrictions enforced in many districts. The local authorities, as a rule, have builders and others on their executive who are

interested in maintaining certain antiquated and costly conditions by means of by-laws. Cheap materials and cheap construction are in this way more or less prohibited. For instance, in many localities the use of wire and plaster for walls, floors and so on is forbidden, although it is strong, impermeable, cheap, easy to handle and construct, and in every way an invaluable boon to the cheap cottage builder. Then there are absurd rules enforced as to foundations, thickness of walls, nature of materials and the like, all of which render cheap buildings hopeless. Why should not models and specifications be lodged with the Local Government Board, and, if approved, be furnished with a certificate of registration which should be a warrant for building under any rural authority? Or is that plan too simple for the department of which Mr. John Burns is the head?

The Future of the Polyclinic.

ADMIRERS of the unique institution in Chenies Street, W.C., will learn with regret that its financial resources are once more strained to breaking point. Indeed, if current reports are to be believed, serious apprehension is felt by the supporters of the London Polyclinic as to its future. A sum of no less than £3,000 must, we understand, be collected within the next few days if the Medical Graduates' College is to continue its good work as a post-graduate centre. The institution differs in many respects from other post-graduate colleges in the Metropolis. In the first place, it is unconnected with any hospital, so that it cannot be said to be "run" by, or in the interests of, any particular medical staff. Indeed, the Polyclinic has shown commendable catholicity during the last few years in the choice of its lecturers and demonstrators. Again, it has become a recognised centre for medical consultations, patients being frequently sent up by their own medical attendants, or in company with them, for the purpose of obtaining a specialist's opinion gratuitously. It is to be hoped that the required sum may be speedily forthcoming, for one could hardly imagine a better and more practical memorial to its illustrious founder, the late Sir Jonathan Hutchinson, and it would be a thousand pities if its work were allowed to languish at this stage for the want of timely support. Those who remember and honour the work of "the grand old man of medicine" might well co-operate to place the "Hutchinson Institute"—as it might advantageously be called—once more upon a secure financial basis.

"Hospital Weeks."

THE inauguration by the London Missionary Society, the pioneer of medical missionary enterprise throughout the world, of a "Hospital Week," from February 8th to 15th, is yet one more sign of the healthful activity in regard to medical matters which has always characterised its policy. A book entitled "Dedicated Science," containing articles by Sir Alfred Pearce Gould and others, has been prepared for the occasion, and will be circulated widely among the supporters of the Society. The annual expenditure of this Society upon medical missions in India, Africa, and China is no less than £26,000, and it is hoped to raise this week a sum of £16,000 for their support. The idea of setting apart a certain week in the year for a specified object, such as the support of a charity, or the waging of a special campaign against national disease, finds growing favour with many, and there is certainly much to be said in support of such a movement. Why should not the hospitals of our country, both small and great, start similar "Hospital Weeks," and in this way solicit the help of those who live or work under their friendy shadow?

LEADING ARTICLES.

THE OPTIMISM OF MR. LLOYD GEORGE.

A COMPLIMENTARY banquet to Dr. Christopher Addison, M.P., on Friday last at the Whitehall Rooms, London, was the occasion of a speech from Mr. Lloyd George on the National Insurance Act. It was natural that the Chancellor of the Exchequer should make the most of the successes and minimise or overlook the defects of the great and complicated measure of which he may claim the authorship. At the same time, it may be well to read between the lines of his speech with a view to a still further extension of his avowed sympathy towards the medical profession. From that point of view, indeed, our remarks may be commended to the consideration not only of the politician in whose honour the banquet was organised, but also of the other distinguished medical men who were present on that occasion, including Sir Clifford Allbutt, Sir John Collie, Professors Leonard Hill and Arthur Keith, Sir Victor Horsley, Dr. A. Latham, Sir Ronald Ross, Sir Arbuthnot Lane, Professors C. J. Martin and Arthur Thompson, Dr. F. W. Mott, Sir Shirley Murphy, Mr. C. B. Lockwood, Professors Sims Woodhead and W. Wright, and Dr. H. H. Mills. The names upon this list, however distinguished in themselves, can in no sense be held as representative of the main body of the medical profession. Incidentally, there is a notable lessening of the British Medical Association element which figured so largely in the earlier stages of the Chancellor's campaign. At the present moment the pregnant fact is thrust upon the world that out of 22,500 general practitioners in Great Britain no less than over 20,000 are on the panel, and that the majority of these came in on January 15th, 1913, that is to say, within the final date of closing the original lists. Summing up the year's work, the Chancellor pointed out that the State had distributed amongst the medical men on the panel four and a half millions of money, or an average of £230 per head. The latter clause of this statement is reported to have been greeted with a cry of "shame," a curious comment from an audience composed largely of medical men meeting in honour of a prominent medical politician. Did the term in question indicate their contempt of any member of their profession not being content with an average of £230 per annum, or that the sum was miserably mean and inadequate? On either horn of this dilemma it has a significance which may well puzzle the average medical man yearning for more light from those responsible for insurance legislation. Mr. Lloyd George may be reminded that this average does not hint at

fairly the extreme payments to panel doctors—on the one hand, the large ones that imply an amount of labour beyond the power of a single man, and the smaller ones which are miserably inadequate. Nor does the magnificent sum of four and a half millions convey any intimation of the vast countervailing sum surrendered compulsorily by the pre-existing club and contract system. Now for the defects of the system, some of them alluded to by the Chancellor, while others were passed over in silence. He spoke of the ruin inflicted upon certain members of the medical profession who had lost their club practice and had not gone on the panel. Mr. Lloyd George expressed his sympathy with these our professional brethren, whose misfortunes have come upon them, be it remembered, mainly because, as honourable men, they kept to a pledge of abstention from the panel given to the British Medical Association. We have no reason to doubt the Chancellor's expression of sympathy, but would it not be more to the point if out of the vast sums which he rightly boasts of spending upon the profession he were to devote a fraction to the compensation of the medical men who, on his own admission, have been indirectly ruined by the Insurance Act? By a man of his character and political resources the fact of any existing want of statutory powers could speedily be remedied. Then, again, let us impress upon Mr. Lloyd George the risk he is running of sowing unending bitterness in the minds of the medical profession if he permits herbalists and other unqualified persons to sign certificates and render other medical services under the Act. If unqualified persons are to be admitted the object of the Medical Acts will be seriously undermined, to say nothing of the central principle of the National Insurance Act, which is to provide a skilled medical service for those unable to obtain it from their private resources. Another grievous defect of the Insurance Act is the want of provision for hospital service. At present the voluntary medical charities of the United Kingdom are treating a large number of insurance patients. In point of fact, they are relieving Mr. Lloyd George of a vast amount of insurance work which he should be paying for out of the vast sums collected from insured and employers and contributed by the State. Many of the special hospitals have been hard hit by the Act and some of them are on the verge of ruin. The Chancellor cannot say of them —as he did of the ruined practitioners—that they have been misled. Their hard case clearly results from the operations of the Act, and by all the rules of fair dealing Mr. Lloyd George should make some provision for these institutions out of his teeming millions. Why should the consultants on the staffs of the hospitals be asked to give their services free to insured persons while Mr. Lloyd George has had all the money he has asked for from the community for the express purpose of providing the best scientific medical treatment obtainable for the insured? If Mr. Lloyd George's frequently-expressed sympathy with the medical profession means anything at all, it must extend to members of the honorary staffs of hospitals, whose interests, especially in the case of the smaller and the special hospitals, are gravely threatened. The names of the medical guests present at the banquet on the 6th hardly suggest any representation of the small or special hospitals among the Chancellor's adherents. Nor do we recall any such representative element in previous negotiations. The only protests on this point, we believe, have been those made in the columns of The Medical Press and Circular. If deprived of their hospital appointments, as some of them will assuredly be, by the inexorable competition of the Insurance Act, the professional career of the ejected will in not a few cases be brought to a disastrous termination. Surely it is time that the altruism of our most optimistic Chancellor dealt in plain downright black-and-white with the relation of the hospitals to his National Insurance Act.

CURRENT TOPICS.

Trouser Skirts.

Man has long since reduced his dress to the lowest depths of dulness and utility. Latterly he has cast off even the traditional frock-coat and tall hat, as superfluous to the needs of daily life. The beauty of this sweet simplicity has not gone unnoted by imitative woman. In spite of the wiles of milliners and dressmakers, she has little by little veered round in favour of male garments. By easy stages the lightly-draped skirt has in this way merged into more or less openly-confessed trousers. One of the latest creations of the fashionable world is the trouser skirt invented by Paul Poiret, of Paris. It is described by the fashion writers thus:—"It is the genuine thing, without compromise of any kind. The trousers are real trousers, with a fashionable central crease and turned-up bottoms, and they are quite separate from the skirt. An elastic band secures them round the waist." That last item—the elastic belt—is, from a medical point of view, likely to counteract any hygienic benefit that might be derived from the adoption of man's nether garments. As well make knives without handles as trousers without braces! It is somewhat curious that the woman who dons trousers should at once hasten to hide them with a skirt, but we presume Poiret, of Paris, knew his business when he placed his hybrid garment upon the fashionable market. Would that his genius might prevail against the high-heeled shoe and the tight-waist corset! Reforms in the corset have so far halted at the thorax. From the standpoint of bodily efficiency and health woman has everything to gain by adopting the rational principles of ease, cheapness, serviceability and comparative simplicity and complete comfort whereby the dress of mere men is regulated.

The Demand for Domesticity.

The State used to be satisfied with saying "Thou shalt not," in the manner of the Decalogue. The negative was the *cachet* of the tyrant. It was definite, short, and easily understood. Now we are ruled by the annoying affirmative of the

bureaucrat. He says, "Do this, and keep on doing it," in a manner vague, tedious and inefficient. We have an octopodal Insurance Act. Other lands are netted in a seine of soldiering. For instance, Germany. And her conscriptors are extending their activity. The women are to be in the case. The suggestion is that every girl at the age of twenty is to do a year's service: six months' household science, three months' care of children, and three months' nursing. The estimated first year's catch is 350,000. *Cherchez la femme* will cross the frontier. We are sorry to think the German girls need this compulsory training, but our sorrow is nothing to our amazement. Where in all the world were women like the Germans? They were paragons of domesticity, the *hausfrau in excelsis*. At least, in such guise have they been represented to us and to the world at large. Apparently no woman is a good housekeeper in the eyes of her husband. Or, perhaps, German husbands want a good deal. Anyway, we are listening to the sturdy old cry about the undomesticated female. It has rung through the ages. Women won't marry and can't cook, and are generally worse in every way than their mothers. They probably always were.

Splenic Enlargement in Childhood.

THERE are many conditions which give rise to enlargement of the spleen in children, and some of them give rise to considerable difficulty in diagnosis. In the discussion upon the subject at a recent meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine, it was pointed out that whereas the chief interest attached to splenomegaly formerly lay in its diagnostic value in various affections, at the present time the condition was rather regarded as a fresh field for surgical conquest. In other words, splenectomy has given results that have proved strikingly and permanently beneficial, even in such a disease as splenic anæmia. The fragility of the blood-corpuscles is an interesting phenomenon which has been observed several times in association with enlargements of the spleen in cases of acholuric jaundice. It is obvious that the spleen may enlarge and undergo structural or functional change in certain cases to serve some useful purpose. In the splenomegaly of blood diseases surgery offers no advantages, but, rather, is contra-indicated. As Sir John Bland-Sutton remarked, "in dealing with splenomegaly the physician is the reliable guide and the surgeon his willing instrument." Experience alone will show how to improve the *technique* of the operation and how to select the cases in which removal of the spleen is favourable.

All Men are Witnesses.

THE traditional classification of witnesses is into three groups: liars, blank liars, and experts. But we are given no help towards defining the various groups. Truth will sometimes spring even from the well of a criminal court, and it is useful to recognise her, not necessarily for publication, but as a guarantee of good faith. What we want is a test for testimony. The average man's powers of observation are absurdly bad. In energetic American universities arrangements have sometimes been made for a remarkably-attired individual to enter a lecture theatre and create a scene with the lecturer. He is ejected after a few minutes, and the lecturer, who is in the know, asks the students, who are not, each to write an accurate and detailed account of the bogus adventurer. The results would not do credit to a sensitive amœba, and might easily lead us to suppose that some sort of sentient paralysis was epidemic amongst the innocent functionaries of the experiment. It is not so. All men are testimentarily uncertain. Some are more so than others, and on the evidence of one man the result of a trial often hangs. We could never correct a man's memory, but we can see if his senses are in good order and find out his co-efficient of credibility. There is no reason, for instance, why persons concerned in accidents should not be medically examined. We often hear absolutely contradictory evidence of simple fact given by parties of an obvious *bona fides*. An examination might tell us on which side more credence could be placed. The fatal objection to such a procedure is that it might tend to smooth the path of justice, and the professional levellers of legal mole-hills would never tolerate anything so like a steam-roller. On the other hand, it might merely increase the number of experts by inventing the "credibility expert" or super-witness.

Inconsistency and Alcohol.

WE are very inconsistent in the views we hold on the alcohol question. As a people we sway indecisively between considering alcohol as part of a pleasant drink, as a poison which rots man's body and ruins his soul, or merely as a useful drug. Nor do we know how to place the alcoholic: whether to treat him as an immoral wretch or as a man grievously sick. Practically we adopt a middle path between sentiment and sense, and, as is usual, employ sense in the general and sentiment in particular cases. We treat dipsomaniacs as a class suffering from a sad form of mental abnormality, and are anxious to do what we can for them. But no one seems to have any sympathy with an individual drunken man. Many of the Canadian hospitals entirely decline to treat patients suffering from over-consumption of the hydroxide of ethyl in any form. The result is what we would suspect. Cases of head injury, cerebral hæmorrhage, and so on, are occasionally turned out to die on the street. It is often impossible to diagnose them when they are complicated by alcohol. The only safe course is to keep all cases in which there is any probable, possible shadow of doubt till such time as the toxic effects have worn off and the underlying injury has become demonstrable. We should be consistent. Alcoholism is a disease and not a bad habit, and comes under the domain of the doctor. It has been said that the wages of gin is breath, but retribution, unfortunately, does not stop there. The first thing to do is to treat each individual inebriate as more or less *non compos*. He should be rescued from the frying-pan of the police court and passed into the purifying fire of therapeusis.

Rescue Apparatus.

DR. J. S. HALDANE, M.D., F.R.S., has just prepared a comprehensive report to the Doncaster Coalowners' Committee (Gob Fire Research) upon the use of self-contained rescue apparatus in irrespirable atmospheres. Seeing that recent legislation has rendered the provision of some form of portable rescue apparatus compulsory at coal mines, it becomes a matter of great responsibility and importance to decide upon the best type to be used. The essential part of a rescue apparatus consists of a bag into and out of which the wearer breathes, arrangements being made for the replacement of the oxygen removed by respiration and for the absorp-

tion, or otherwise removing, of the carbonic acid given off in the expired air. It is necessary, of course, that such an apparatus shall be safe, efficient and good for working for a period of at least two hours. Liability to failure on the part of a rescue apparatus is as dangerous as similar liability to failure in an aeroplane. It is also important that vision and hearing should be interfered with as little as possible. Helmets are at a disadvantage in these respects, and a half-mask is stated to be preferable to a mouthpiece. A number of fatal accidents with rescue apparatus seem to have been caused by leakage, rendering them unsafe for use in poisonous air. The ideal form of apparatus does not yet appear to have been evolved, but Dr. Haldane is still engaged in further researches, and it may be hoped that in course of time some really efficient type may be forthcoming that will prove worthy of adoption by all workers who have occasion to use such a contrivance.

Unqualified Practice under the Insurance Act.

The important point of the payment of unqualified practitioners under the National Insurance Act has been frequently discussed in our columns. The whole matter hinges on the decision of the Insurance Commissioners that such contributions may be made by local committees. This permission has been actually carried out in several places. In Worcester, for instance, some six or eight persons are said to have made arrangements for attendance by herbalists. If this course be upheld by Government it will clearly open the door to any sort of unqualified practice. Take the case of the cancer quack; what is to prevent a local committee from sanctioning his attendance any more than that of any other notorious charlatan? As things stand at present, then, it is open to the local committee to lend their sanction to any form of unqualified practice. A result of that kind is likely to give rise to deep and bitter resentment among members of the medical profession. Even the General Medical Council will probably be roused thereby from its wonted somnolence. A timely and unanimous protest has been raised by the Council of the National Medical Union against the obnoxious recent regulation of the Commissioners. The objection was raised on the ground of the regulation "containing provisions which seek to legalise the treatment of those insured under the Act by persons who are not duly qualified practitioners." Mr. Lloyd George and the Government will do well to nip this innovation in the bud unless they want to have another pitched battle with the medical profession.

PERSONAL.

H.M. the King has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of Dr. John Carswell, F.R.F.P.S.Gl., L.R.C.P.Ed., as a Medical Commissioner in Lunacy for Scotland.

Dr. Douglas Firth, M.D.Cantab., M.R.C.P.Lond., has been appointed Assistant Physician to the Royal Free Hospital.

Sir G. H. Philipson, M.D., previously Vice-Chancellor, has been appointed a Pro-Vice-Chancellor of the University of Durham.

Dr. G. Stewart Abram, M.B., B.C.Cantab., has been appointed Honorary Physician to the Royal Berkshire Hospital, Reading.

Dr. J. Patrick Cullen, M.D.Lond., D.P.H., has been appointed Deputy Medical Officer of Health to the Metropolitan Borough of Poplar.

Surgeon-General W. B. Bannerman, I.M.S., has been appointed an Honorary Physician to H.M. the King, vice Surgeon-General J. Richardson, deceased.

Sir Lambert H. Ormsby, Past President of the Royal College of Surgeons of Ireland, has been appointed Representative of the College on the General Medical Council.

Dr. Joseph Rutter, M.D., of Wilbury Gardens, Hove, who died on December 16th, aged 79, left estate of the gross value of £30,665, of which £28,720 is net personalty.

Dr. E. Farquhar Buzzard, M.D.Oxon., F.R.C.P. Lond., has been appointed an additional Consulting Physician to the Royal Hospital for Incurables, Putney Heath.

A handsome stained-glass window was dedicated the other day in Bromsgrove Parish Church by the Bishop of Liverpool, in memory of his brother, the late Sir Thomas Chavasse, M.D., F.R.C.S., of Birmingham.

Mr. J. W. Thomson Walker, F.R.C.S., will preside at the forthcoming dinner of the Edinburgh University Club to be held on Friday, February 20th, at 7.15 p.m., at the Wharncliffe Rooms, Hotel Great Central.

The Home Secretary has appointed Mr. Arthur H. Norris, M.R.C.S., L.R.C.P., to be Medical Inspector of Reformatory and Industrial Schools, as from April 1st, 1914.

Dr. Robert T. Edwards, of Swansea, has been appointed Medical Officer of Health and Medical Inspector of School Children to the Merioneth County Council.

We are glad to learn that Dr. F. M. Sandwith, Gresham Professor of Physic, who underwent a very severe operation three days after delivering his last lectures, is making a good recovery. It will, however, be several weeks before he can resume work.

Dr. Arnold Chaplin, M.D., F.R.C.P., will deliver the annual Hunterian Oration before the Hunterian Society to-night, in the library of St. Bartholomew's Hospital, on "John Hunter and His Work, and the Past and Future of the Medical Profession."

Colonel Clement Godson, M.D., V.D., formerly president of the British Gynæcological Society, consulting physician to the City of London Lying-in Hospital and St. Peter's Home, Kilburn, a former Master of the Shipwrights' Company, left estate of the gross value of £48,492, of which £44,633 is net personalty.

We regret to learn, as we go to press, of the mishap sustained by Mr. Mayo Robson, the well-known Surgeon, who was accidentally shot through the thigh by a gun-bearer in Nairobi. Fortunately the injury was not a grave one, and he is reported to be progressing favourably.

The Secretary for Scotland has appointed, under the provisions of the Mental Deficiency and Lunacy (Scotland) Act, 1913, Miss Kate Fraser, M.D., Ch.B., D.P.H., at present Medical Officer to the Govan Parish School Board, and Dr. James P. Sturrock, M.D., C.M., at present Medical Superintendent of the Criminal Lunatic Department, Perth, to be Deputy Commissioners of the General Board of Lunacy for Scotland, which, after May 15th next, will be designated the General Board of Control for Scotland.

CLINICAL LECTURE

ON

THE OSSEOUS AND ARTICULAR MANIFESTATIONS OF INHERITED SYPHILIS IN THE CHILD.

By DR. SAVARIAUD,

Surgeon to the Trousseau Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

FAILING a knowledge of the osseous manifestations of inherited syphilis in children, you will be liable to errors of diagnosis as detrimental to your reputation as they are fraught with danger to the little patients.

In private practice of a good class you are, of course, able to obtain information as to the antecedents of the parents, so that you may be on the look-out for the earliest signs of this terrible disease, but, apart from the fact that the osteo-articular affections of a child, the offspring of syphilitic parents, are not of necessity syphilitic, how often does it happen that the history of the disease is suppressed or is unknown. For want of this all-important piece of information you run the risk of taking for a sprain, a fracture, osteomyelitis, tuberculosis or cancer, what, after all, is merely syphilitic osteitis.

If you wish to avoid such mistakes you must ever bear in mind: (1) The constitutional signs of syphilis in the child; (2) the special features of these osteo-articular manifestations.

An instance of the kind will open your minds to the importance of the diagnosis. Some years since, when I was medical registrar, they brought me a girl, æt. 4, with a painful swelling of the humerus just above the elbow. The mother told me her child had fractured the arm about a year since, for which it had been placed in a plaster splint for a month, and since then the arm had never been quite well. Radiography, however, did not show any fracture, but revealed grave changes in the bone, with a central sequestrum and new bone formation. It was apparently a case of chronic osteomyelitis, and on operation the diagnosis appeared to be confirmed. The child left the clinic before she was quite well, but returned soon after with signs of arthritis in the opposite elbow. This time it was not the humerus, but the ulna that was attacked, and it was distended like a bone with *spina ventosa*. There was fluctuation over the ulna and the skin felt hot. I again took it to be chronic osteomyelitis, and intervened. I found a central sequestrum bathed in pus, embedded in fungating and gummatous *débris*. This, of course, made me diagnose syphilis, and the child was put on appropriate treatment. In spite of this the child came back to us some time after with pain in the femur and hip, and coxalgia was thought of. Radiography, however, showed double osteitis of both femora. On one side the lesion reached up to the neck of the femur, thus explaining the symptoms of coxalgia.

On questioning the mother we learned that when four months of age the infant had had "paralysis" of all four limbs, for which she had been given injections under which the condition soon cleared up.

Now, this child may very well serve as the text of my discourse. At four months of age she already presented signs of heredo-syphilis (Parrot's pseudo-paralysis). The lesions retroceded under the influence of treatment, then recurred in the form of multiple osteitis which not improbably had been present ever since birth. In the absence of the correct diagnosis the lesion had been mistaken for fracture and osteomyelitis calling for two operations which, to say the least, were unnecessary, and narrowly escaped being put up in plaster for supposed coxalgia.

I will now discuss with you the different forms of syphilitic osteitis according to the age of the child. In text-books it is customary to describe three sorts of accidents according as the disease occurs in a baby, in a child between two and five years of age and in the adolescent.

(1) *Osteo-syphilis in the Newly-born—Parrot's Pseudo-paralysis.*—During the first six months of life we are apt to get severe pain in the long bones of all four limbs which may culminate in separation of the epiphyses causing functional impotence simulating actual paralysis. But while paralysed infants have no pain, children suffering from Parrot's disease cry out on the slightest touch or when we try to move the limbs. On examining the bones we find that they are enlarged, especially round about the larger joints. The swelling is very tender and occasionally we meet with abnormal mobility and, should there be separation of the epiphyses, cartilaginous crepitation.

One of the most salient features of the lesion is that it is nearly always symmetrical; indeed, it may occur in all the four limbs. These characters enable us to differentiate syphilitic osteitis in babies from any similar affection, such as fracture and paralysis of obstetrical origin. Osteomyelitis and tuberculosis do not usually attack young infants, rarely suppurate and are rarely symmetrical.

Lastly, the diagnosis will be confirmed by other signs of heredo-syphilis such as palmar psoriasis, pemphigus bullæ, and the smooth, shiny appearance of the skin of the palms and soles, various eruptions, papules, mucous patches, fissures and scars at the labial commissures, round the anus, and gluteal ulcers.

Then, too, the flat bones of the skull may be attacked: frontal exostoses, medio-frontal hyperosteosis and abnormal prominences on the parietal bones (natiform skull).

In short, whenever in a newly-born infant we find a painful affection of the four limbs with juxta-articular swelling and functional impotence, we must think of syphilis. A detailed examination of the little patient will then reveal the stigmata of the disease.

(2) *Osseous Manifestations of Syphilis during the First and Second Periods of Childhood.*—This form may follow the first, as in our patient. In this case, as the bone increases in size, the hyperostosis extends *away* from the joint and attacks the diaphysis. When syphilis manifests itself between two and four years of age it is always the same bones that are attacked: the long bones and the flat bones of the skull and face, as a rule quite symmetrically.

Just as in the baby, there may be involvement of the neighbouring joint when the epiphysis itself is attacked. Here again the affection is very pain-

ful. The pain is worse at night (osteoscopic pain) and it is especially the superficial bones that are attacked (tibia, ulna, clavicle, frontal, parietal, etc., bones)—at any rate this was thought to be the case until radiography came to our aid by enabling us to detect lesions of bones masked by thick muscular layers (humerus, femur, fibula).

The lesions are usually diffuse. The hyperostosis forms a sort of sheath round the diaphysis. The original seat of the inflammation is in the marrow and beneath the periosteum. The medullary canal may become obliterated by condensing osteitis, especially in old-standing cases. The bone is denser than normal. Lastly, and this is the earliest symptom, the irritated periosteum begins to form fresh bone so that ere long the old bone is surrounded by a sheath of newly-formed bone and clinically this is felt as a diffuse, very tender, periosteitis. Radiography enables us to obtain a clear idea of the nature and extent of the lesions.

In addition to this diffuse sheath-like swelling we often get localised hyperostosis, perceptible on palpation and visible with the X-rays, nodes and hyperostoses can be made out on the tibiæ and the ulnas, the edges of which are rounded. In the long run the nodes soften, the skin reddens and then breaks down over a large circular area and through the sharp-cut, punched out wound there exudes gummatous and bony detritus, the colour of chamois leather, quite characteristic of syphilis. In the absence of specific treatment this loss of substance may undergo transformation into obstinate ulceration with, at the bottom, a piece of necrosed bone, greyish or blackish and worm-eaten, which takes a long time to come away.

The "revelation bone" *par excellence* in syphilis is the tibia. Its form is characteristic, it is thickened throughout, it may be increased in length and its anterior margin has become convex forwards. Its inner surface is covered with lumps which ultimately soften and evacuate their contents, giving rise to obstinate ulcers with a sequestrum at the bottom.

Independently of these changes in the long bones we often meet with changes in the flat bones. hyperostoses or gummata of the frontal or parietal bones. These do not present any hyperostosis, but, what is vastly more serious, they undergo necrosis and absorption entailing great loss of substance. It is in this way that we get breaking down of the bony framework of the nose or perforations of the hard palate, ulceration and subsequently stricture of the pharynx, etc.

The second crop of teeth are gravely attacked during growth. The upper median incisors present the most typical changes. The crown, instead of being spatula shaped, tends to become pointed, conical, or there may be extensive semicircular loss of substance on the lower border (Hutchinson's teeth). The dental changes, deafness and infiltrations of the cornea constitute Hutchinson's triad.

Failing these somatic signs, we must enquire into the mother's antecedents—numerous abortions early in pregnancy, infants still-born or dying soon after birth.

Lastly, in most cases of heredo-syphilis, the general health is as a rule the more affected the earlier the disease manifests itself. These infants are mostly debile, miserable-looking and anæmic. Iron proves useless, whereas arsenic and mercury work wonders.

(3) *Delayed Manifestations of Osseous Heredo-Syphilis.*—It must be borne in mind that the diathesis may remain latent throughout childhood and manifest itself first during adolescence or even in adult life in the shape of the characteristic deformities of the tibia. In these cases we rarely find the stigmata of heredo-syphilis, so that they are readily mistaken for cases of chronic osteomyelitis and operated on.

In the absence of antecedents, laboratory research (Wassermann-Noguchi) and a trial of specific treatment will clear up any doubt.

Articular Lesions.

Syphilis has a particular predilection for the diaphyses, that is to say, the long bones, but the epiphyses or articular ends of the long bones are not exempt. Often the body of the bone and one of its ends are attacked at the same time, in which case we get joint trouble. That is met with at all ages. The commonest form is double hydrarthrosis of the knees. This is indolent and the effusion is moderate in amount. There is no fungous tissue as in tuberculosis, but the synovial membrane here and there may present patches of thickening which are really gummata. They are of unlimited duration unless treated. The bilaterality, the indolence of the affection and the absence of fungous tissue constitute the basis of the diagnosis.

Side by side with this hydrarthrosis we are apt to get osteoarthritis or pseudo-white tumours, in which there is hyperostosis of the ends of the bones which are worn, as in dry arthritis, and the joint is more or less dislocated. The striking characteristic here again is indolence which might lead us to suspect dry arthritis, but the absence of grating and the fact that the diaphysis shares in the hyperostosis, the thickening localised of the synovial membrane and, lastly, the young age of the subjects, are in favour of syphilis.

Treatment.—The treatment of these cases is almost entirely medical: mercurial inunctions or in the form of injections of the soluble salts. Surgical treatment can only be required for the removal of sequestra when quite movable. Operations are often performed in these cases under the mistaken impression that they are chronic osteomyelitis, but, to put it mildly, they are unnecessary, indeed they may be distinctly injurious in the sense that the bone removed is not reformed so that we may get a pseudo-arthrosis. This is a mistake which few surgeons have not at one time or another fallen into, but it is an extremely disastrous mistake, because the wound does not usually heal and the patients can go on suffering and suppurating until they are placed on the sole treatment capable of putting matters right.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by J. M. G. Swainson, F.R.C.S., Assistant Surgeon to the Westminster Hospital, Surgeon to the Bolingbroke Hospital. Subject: "The After Treatment of Surgical Cases."*

ORIGINAL PAPERS.

VENEREAL DISEASE—SOME NOTES ON THE ADMISSIONS TO THE WESTMORLAND LOCK HOSPITAL, DUBLIN, SINCE THE YEAR 1860. (a)

By G. PUGIN MELDON, F.R.C.S.I.,
Senior Surgeon, Westmorland Lock Hospital, Dublin.

"The Westmorland Lock Hospital was opened on the 20th of November, 1792, for the indiscriminate admission, without recommendation, of indigent persons afflicted with venereal disease, and was placed under a

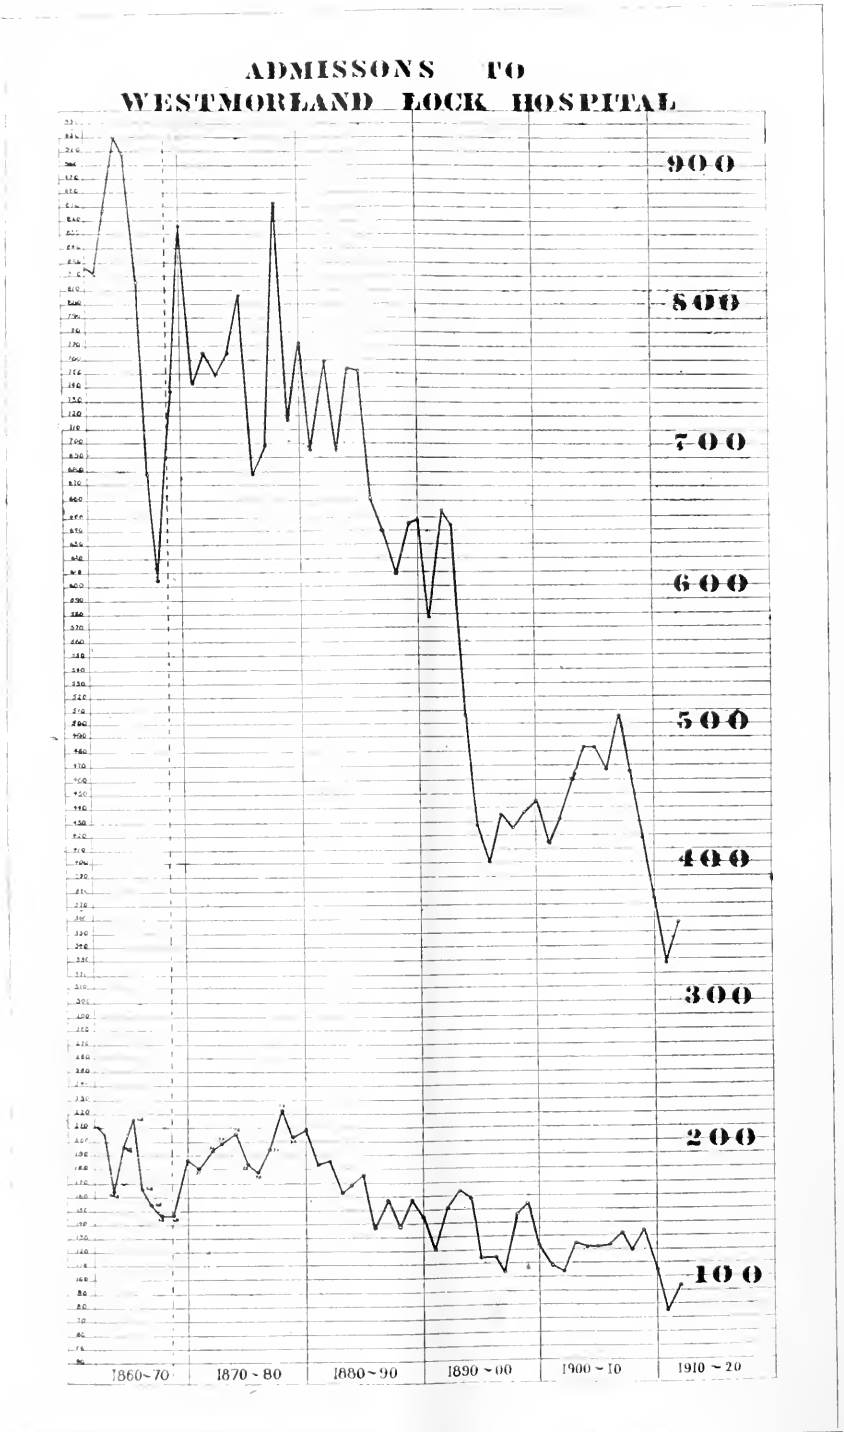
(a) A paper read before the Section of State Medicine, Royal Academy of Medicine in Ireland, January 16, 1914.

Board of Directers, consisting of five physicians and nine surgeons."

So opens a "Report upon Certain Charitable Establishments in the City of Dublin" in the year 1809. The report further states that "this arrangement was found to be defective so far as the surgeons were concerned, as, with the exception of a few individuals, the attendance from the beginning was irregular," and mentions that in 1796 the Board of Directors was convinced that, where a daily and laborious duty is required from professional men, they have a fair claim to be paid for their time and trouble. As a result of this salaried medical officers were appointed.

The Hospital at this time accommodated 300 patients, and, as it was somewhat smaller than at the present day, it must have been sadly overcrowded. Containing, as it did, both male and female persons of a not very orderly type, it is not surprising that certain abuses arose, which led to the removal of the male patients, in 1820, to special Lock wards in Dr. Steevens' Hospital. Since that date the Hospital has been solely for the accommodation of women.

The Fever and Lock Hospital, St. John's Street, Limerick, was first opened with three beds on February 23rd, 1781. It was subsequently enlarged, and accommodated both male and female patients



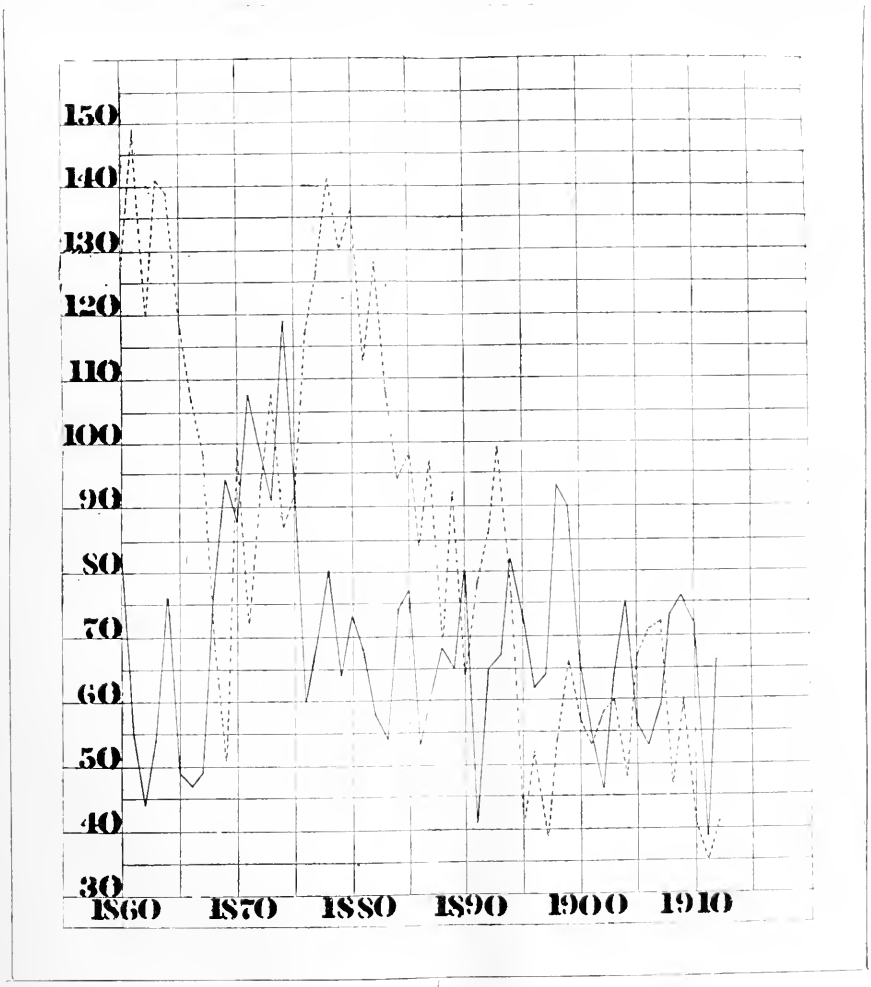
It was, however, closed in the year 1849 "consequent on the increase of cholera."

After the passing of the Contagious Diseases Act of 1868, two Lock hospitals for women were opened—one in Cork on June 15th, 1869, and the other in Kildare on December 6th of that year. The former contained 46 and the latter 42 beds. They were under military control, and ceased to exist after the repeal of the "C.D." Act in 1888. From this time the Westmorland Lock Hospital has been the only institution of its kind in Ireland, and I believe that the majority of prostitutes in Ireland, sooner or later, find shelter within its wards.

In looking through our hospital registers, especially earlier ones, I found a certain number of patients who, apparently, were not suffering from venereal disease. It seemed to have been the custom to send cases of scabies and pediculosis to the Lock Hospital, and until quite recently we felt bound to admit such cases, simply because they had always been considered suitable cases for the Lock Hospital. It was at the suggestion of my colleague, Mr. Henry Moore, that we refused to admit these cases, and now confine our admissions to patients suffering from venereal disease. I have excluded all non-venereal cases from the list of first admissions in the accompanying charts.

On Chart I. you will see two curves—the upper one represents the total number of admissions and re-admissions as shown by the register of each year since 1860; the lower curve shows the number of "first" admission patients for these years. Both curves show a very considerable fall from the middle sixties down to recent years. This decrease in number might be attributed to a corresponding diminution in the numbers of infected women. I do not think that this conclusion is justified, because there come into play other factors, three of which are of very great importance—the severity of the disease, the clearing out of disorderly houses in the city, and the type of woman afflicted with venereal disease.

As regards the first of these, I believe that fifty years ago the various venereal manifestations were of great severity and have gradually become milder. I have noticed this amongst the hospital patients even during the past ten years. A patient does not usually present herself for admission until she is suffering very considerable discomfort or finds herself unfit to continue her avocation. As long as she suffers comparatively little inconvenience either she remains untreated or, at least, visits one of the various dispensaries, probably at very irregular intervals. So with less acute symptoms there would be fewer seeking admission to the hospital.



Up to about the year 1899 most of the brothels were collected in a comparatively small area on the north side of the city. In most of these houses there was someone in charge who insisted on a girl going into hospital as soon as she was known to be diseased; some of them, I believe, had their own medical attendants, who periodically inspected the inmates and ordered venereal cases into hospital. A good number of our admissions in past years were such patients who would not have come of their own accord. For several years these houses were being closed up, and their inmates scattered throughout the city and suburbs without the semblance of supervision. The curves, I think, show the effect of this on the numbers of admissions.

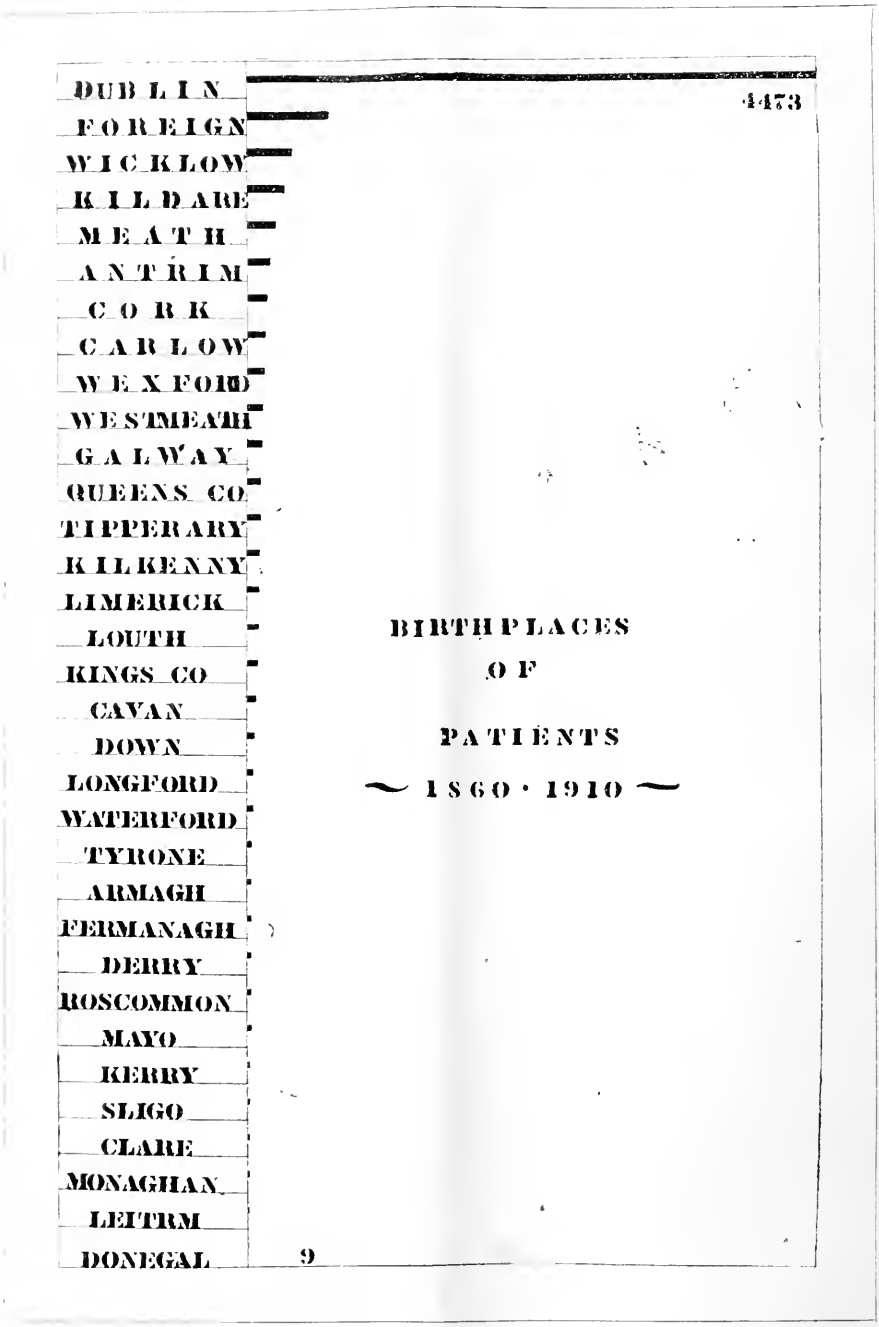
The type of woman suffering from venereal disease has altered considerably; the regular women of the

town are tending to be replaced by those who follow some other occupation as well as that of prostitution. The latter, naturally, have a greater objection to applying for admission to the Lock Hospital than the former, and so seek treatment elsewhere. The effect of the Contagious Diseases Act of 1866 and 1868, although applying only to Cork, Queenstown and the Curragh, seem to have caused an increase in the admissions.

The upper curve, including as it does all classes of cases and re-admissions, is not of great importance, but is of some interest as a sort of rough estimate of the efficiency of treatment. In the old days, when cases of acute secondary syphilis were discharged "cured" in two or three weeks, it is not surprising that the re-admissions were very frequent and the upper curve unduly high as compared with the first admission curve. In the decade 1860-1870 the proportion was over 4.9 to 1; while in the ten years ending 1912 the proportion is 3.66 to 1; and in the current year, which does not end till March 31st, the figures are 2.68 to 1.

You will notice a great fall in the year 1911; this, I believe, was due to a special factor which I shall deal with presently.

On Chart II. there are two curves; the one drawn with a continuous line represents those first admission cases who suffered from syphilis, and the broken line non-syphilitic cases, suffering chiefly from gonorrhœa.



There was sometimes considerable difficulty in placing the cases in their right class because the diagnosis was occasionally hard to decipher, and also at times quaint. Such entries as "external gonorrhœa" and "gonorrhœal sore throat" were somewhat puzzling. Up to the year 1856 most of the entries for syphilis were of the tertiary stage, and very few secondary or primary, so that one is rather led to the conclusion that syphilis in its early stages was often undiagnosed.

After the passing of the Acts of 1866 and 1868 one notices a great increase in the number of syphilitic cases. This increase, which you see is continued for some years, is all the more remarkable because the Lock Hospitals for women in Cork and Kildare were opened in 1869. That there was an increase of syphilis in this country is likely, but that there was also, during these years, more attention paid to the diagnosis of chancres and secondary syphilis is shown by the more careful noting of the characters of the former and the appearance of the latter in the hospital registers.

If you look at Chart II. you will see that the decrease in the number of first admissions in the year 1911 is nearly entirely due to the falling off in the number of syphilitic cases. In this year "salvarsan" came into general use, and was tried in most of the Dublin hospitals. As a result, many cases of syphilis were treated in the general hospitals which, normally, would have been sent to the Lock.

I have drawn up a table and a scale chart showing the birth places of our first admissions for the fifty years ending April 1st, 1910. It will be seen that Dublin supplies more than half our patients, and the counties without large or garrison towns send us very few indeed.

I think it may be said that outside the larger towns there is very little venereal disease in Ireland.

The total number of our "first" admissions during the twenty years ending 1912 was 2,468. Of these, 518 were sent to Magdalen Asylums, to their people, to situations, or otherwise given a chance to reform. About one-half, I am afraid, returned to the "streets," so that in the twenty years about 2,209 girls came upon the town, or a yearly average of 110.45. I should estimate the average time for a prostitute on the town to be about nine years. If we multiply our yearly average of "recruits" by nine we get 994. So I think that the number of our first admissions might be taken to represent a floating population of prostitutes of about 1,000. This figure was somewhat higher than I expected, but still I believe it is as accurate as is possible at the present time.

BIRTH PLACE OF "FIRST" ADMISSION PATIENTS FROM 1860-1910.

Since making these calculations I found two statements in Dr. John Morgan's book, written in 1872, which are of interest: "In Dublin . . . about 1,000 women are known to the police as living an irregular life"; and further on we find: "About every eight or ten years a generation of these unfortunates will have passed away."

It would seem that in the past forty years these matters have not altered very much.

I wish to express my indebtedness and gratitude to Dr. D. Harrington, the Resident Medical Officer at the Westmorland Lock Hospital, for the many hours he spent in helping me to collect these statistics.

THE DIAGNOSIS OF POSTPYLORIC (DUODENAL) ULCER BY MEANS OF SERIAL RADIOGRAPHY. (a)

BY LEWIS GREGORY COLE, M.D.,
Professor of Radiology to Cornell University Medical College.

IN previous communications evidence has been assembled to show that the portion of the gastro-intestinal tract, previously termed the first or ascending portion of the duodenum, pars superior horizontalis, or bulbus duodeni, is not part of the duodenum, but really belongs to the stomach. The popular name, cap of the stomach, or the scientific name, pilleus ventriculi, has therefore been applied to it. Accordingly the term postpyloric ulcer, or ulcer of the cap, should be substituted for "duodenal ulcer," and will be used herein except in quotations. The diagnosis of postpyloric ulcer and its differentiation from and relation to malignant and non-malignant lesions of the stomach forms one of the firing lines of surgical advance. The importance of this field of work is evidenced by the communications of Wier, Moynihan, Codman, Mayo, and others, who have adequately described the clinical and surgical aspects of the subject.

Considering the part that radiology has played in medical and surgical diagnosis, it is appropriate that serial radiography should be an active scout in the detection of ulcers of the cap. Communications, having a direct or indirect bearing on the radiographic diagnosis of gastric and duodenal ulcers, have been published by Hemmeter, Holzknecht, Schwartz, Ashbury, Haudek, Strauss, Kreuzfuchs, and Pfahler. Two diagnostic methods have been employed. One is based on symptom complices, or groups of clinical manifestations, some of which are recognised by fluoroscopy or radiography. But they are symptoms only, as the name suggests, and not direct evidence of the lesion. The other method depends on the contention that bismuth will adhere to the surface of an ulcer or lodge in its crater. Failure to differentiate such flecks from retention in the normal cap is the weak point in this theory. Haudek's "niche" is a finding of undoubted significance. But it very frequently occurs in extensive inoperable carcinoma of the lesser curvature; and furthermore must be carefully differentiated from a small deposit in a pouch of the œsophagus near the cardia.

Strauss's (1) excellent article on duodenal ulcer covers many of my observations, some of which have been published (2), but certain of his deductions do not correspond with my interpretation of the phenomena presented. He bases the diagnosis of ulcer on a rather elaborate symptom-complex, which he has compiled.

Strauss's remarks that Roentgen-cinematography may some time prove of great diagnostic assistance brings me to the crux of my communication. The *technique* of serial radiography, and especially the relative value of serial radiography and Roentgen-cinematography have been fully explained heretofore (3). The gist of it is that 24 instantaneous radiographs of different phases of different cycles, made in rapid succession, are of more diagnostic value than 24 radiograms of different phases of one cycle. *Technique* aside, we pass at once to a description of the anatomy and physiology of the pars pylorica, pyloric sphincter, and pilleus ventriculi, as observed by means of serial radiography, a comprehension of which is essential before we discuss the diagnosis of pathological lesions of the cap.

(a) Paper read at the Section of Radiology, International Congress of Medicine, London, July, 1913.

During the stage of systole, or seven-tenths of the gastric cycle, chyme is expelled through the lumen of the pyloric sphincter into the pilleus ventriculi. The remaining three-tenths of the cycle are consumed by diastole, when the sphincter contracts and closes the lumen. There is no evidence of a periodical opening and closing of the pyloric sphincter independent of the gastric cycle. The cap acts as a reservoir, where the finishing touches of gastric digestion are applied to the small amount of chyme, thus isolated from the bulk of food in the stomach. It is evacuated by a periodical propulsive peristalsis of the descending duodenum. The cap corresponds in diameter and contour with the pars pylorica, and is separated from it by a space of about a quarter of an inch, which indicates the pyloric sphincter. The lumen of the sphincter is centrally located, and at first about one-eighth of an inch in diameter during the systole. As digestion proceeds, it gradually relaxes until, during the later stages, it is twice as large as at first.

The method of diagnosing postpyloric ulcer, employed by the author in 500 cases, is based on the recognition by means of serial radiography of a constant deformity of the cap or sphincter, caused by the induration or cicatricial contraction surrounding the crater of the ulcer. These findings can only be recognised by studying individually and collectively a large series of plates, and either matching them over each other, or reproducing them cinematographically.

The induration surrounding an ulcer projects into the lumen of the cap, causing a displacement of bismuth, as constant as one's finger-prints in a ball of putty. It may be so small that its projection presents only a constant dent in one side of the cap, or it may be so extensive as to distort the lumen of the cap beyond recognition. The induration may involve one-half of the cap, without distorting the other half. In such a case the entrance of the lumen of the pyloric sphincter is an important guide in determining the centre of the cap.

Moynihan (4) states that the ulcer may be separated from the pylorus "by a healthy margin of bowel." When this occurs, the pyloric sphincter has the normal appearance previously described, and the small margin of healthy bowel is distinctly visible in some of the radiographs. In other cases where the ulcer is "just to one side of the pyloric ring, and may involve it" (Codman) (5), one side of the pylorus is the width of the ulcer, plus the thickness of the sphincter, while the other side is three-sixteenths to one-quarter inch thick, having a perfectly normal appearance. The induration may be sufficient to cause a partial obstruction, and when the ulcer heals after a gastro-enterostomy, the induration subsides, and the chyme renews its passage through the duodenum. Where "the cicatricial contraction results in a formidable narrowing of the lumen of the gut" (Moynihan), it is doubtful if the course through the duodenum would be re-established after a gastro-enterostomy.

The puckering from the cicatricial contraction may cause a deformity equally as great as the induration. Indeed, it is doubtful if one can determine radiographically whether the deformity is due to induration of adhesions, or which predominates. Frequently one observes a band of adhesions passing over on the gastric side of the sphincter, distorting the contour of the extreme pyloric end of the stomach. This manifests itself most frequently by a fold on the lesser curvature about half an inch from the sphincter. I have observed this fold in all degrees, from a slight crease, which I interpreted as a congenital lack of expansion at the attachment of the gastro-hepatic ligament, to one that was so extensive that it caused pyloric obstruction. This gives a peculiar form to the stomach, resembling an early fœtus. I think this is what some observers refer to as a "snail stomach," although that term is usually associated with gastric malignancy.

The "pouching," described by Moynihan as "a piece of the duodenal wall, which seems almost separated from the rest, being pinched away from it," is most interesting. Even his wording describes the radiographic findings in a manner that I cannot improve upon. I have always referred to it radiographically as a dilatation of the uninvolved portion of the cap.

In many normal cases the cap is filled or even distended at a certain period after ingestion, while the stomach is empty. Failure to recognise this phenomenon has led to many erroneous diagnoses of pre- and post-pyloric ulcers, based on the contention that bismuth adheres to the surface of the ulcer. I suspect that the "flecks of bismuth," which Kreuzfuchs supposed were in the craters of ulcers, were in some instances persistent accumulations of bismuth in these pouches. The pouch, especially if it is on the under surface of cap and rather large, may retain bismuth for a longer period than the normal cap. Therefore, the continued presence here of bismuth for an extended period is additional indication of postpyloric ulcer.

"Narrowing of the lumen by massive deposits of lymph, or by firm contraction of the scar of an ulcer which has healed," described by Moynihan, could certainly be shown by serial radiography. In some cases this is associated with rapid evacuation of the stomach, but when it reaches such a stage that the lumen is less than that of the pyloric sphincter, gastric retention begins. The degree of gastric retention requiring surgical interference is an open question. Holzknecht considers a six-hour retention abnormal, while Moynihan defines a twelve-hour stasis as indicative of surgical intervention.

Many series of radiographs show constant permanent irregularities of the cap that are much smaller than the pathological lesions previously described. These radiographic findings correspond with Codman's pathological description of healed ulcers, in which a localised area of the muscular coat has been destroyed, and replaced by non-elastic connective tissue. Codman acknowledges that such areas are difficult to detect at operation or autopsy, even when a surgeon is looking for them, and I think that these areas correspond with the lesions described by Bloodgood as non-ulcerative lesions in this region. The frequency with which they are recognised radiographically corroborates Codman's contention that ulcers of the cap occur much more frequently than one suspects. And it also indicates the frequency with which ulcers heal without surgical interference. In such cases the clinical history must be considered in determining whether these slight, constant deformities are sufficiently extensive to require surgical interference or to be observed surgically, especially if the surgeon is averse to the diagnosis of postpyloric ulcer, and is looking for an appendix, Lane's kink, or something else.

A positive differentiation between post-pyloric ulcer and adhesions of the cap from gall-bladder infection cannot always be made exclusively from the radiographic findings. Gall-bladder infection usually presents a more extensive involvement of the pylorus and cap. It may involve the greater curvature and draw the stomach to the right, causing an angulation of the cap. The cap may be involved in the adhesions, but not more so than the pyloric end of the stomach, and there is no evidence of a localised area of induration of the cap, nor is obstruction of its lumen so frequent. This differential diagnosis between post-pyloric ulcer and gall-bladder infection is of more scientific interest than practical value, because in either of these conditions surgery is indicated, if the lesion is sufficiently extensive and associated with symptoms.

Having considered the positive diagnosis of chronic ulcer, and evidences of lesser lesions, probably healed ulcers, and their differentiation from gall-bladder infection, we may now consider the negative diagnosis of post-pyloric ulcers. If one radiograph out of fifty shows a perfectly symmetrical cap, and a normal pyloric sphincter, as previously described, one is justified in making a negative diagnosis of postpyloric ulcer.

Adhesions from postpyloric ulcer may involve other organs, the hepatic flexure of the colon, the stomach of the duodenojejunal junction, where the lower end of the C-shaped duodenum lies in close proximity to the cap. Sometimes the symptoms of adhesions of the colon are more marked than those of the

ulcer itself, and lead to a radiographic examination of the colon rather than of the stomach. It is therefore wise in all cases of adhesions of the hepatic flexure and first portion of the transverse colon to make a radiographic examination of the stomach and duodenum. When adhesions from an ulcer of the cap involve and obstruct the lower end of the C-shaped duodenum, there is an unusual dilatation of the descending and horizontal portions, causing the sausage-shaped duodenum referred to by Holzknecht. This sausage-shaped appearance is not necessarily an indication of ulcer of the cap, however, as it is more likely to present, in cases of chronic obstruction of the duodenum by the root of mesentery, a condition described by Codman. The same obstruction at the duodenojejunal junction may also be caused by ulcers on the posterior wall of the stomach.

Diagnosis by serial radiography may seem like a very elaborate and therefore expensive method; but considering the obscurity of these lesions, and the fact that the negative or positive diagnosis of postpyloric ulcer by serial radiography is equally as accurate as the radiographic diagnosis of renal or ureteral calculus, one is justified in expending an unlimited amount of energy in detecting and differentiating this from other lesions.

By the use of serial radiography, previously described by the present author, George (Boston) has been able to diagnose postpyloric ulcers with a degree of certainty equal to that of the work herein reported.

With one exception all of the cases illustrating this article have been proved by surgical procedure. Lack of space has necessitated the omission of many other proven cases of equal interest.

THE STUDY OF DISEASE IN THE DOMESTICATED ANIMALS: ITS IMPORTANCE TO THE COMMUNITY.

WITH A PLEA FOR AN ANIMAL HOSPITAL. (*a*)

By ERNEST GLYNN, M.A., M.D.Cantab., F.R.C.P. Lond.,

Professor of Pathology, Bacteriologist and Pathologist, Liverpool Royal Infirmary.

(*Concluded from page* 125.)

INFECTIVE DISEASES OF ANIMALS APPARENTLY NOT COMMUNICABLE TO MAN.

Cattle Plague or Rinderpest.

CATTLE plague or rinderpest is the most deadly of cattle diseases. It is produced by an ultramicroscopic organism.

In the second half of the eighteenth century it is estimated that 200 million cattle were destroyed. The disease invaded England and "raged off and on between 1865 and 1869, and was stamped out successfully by the slaughter of all infected animals and of all animals which had been in contact with such infected animals; it cost the country in compensation for cattle slaughtered and other expenses £1,119,994." "It came again in 1877, and cost £13,423 in compensation for animals slaughtered to prevent its spread, and since that date has not reappeared in this country" (Stockman).

The Transvaal lost in 1897 over 2 million cattle.

The treatment is so unsatisfactory that it is legally prohibited in all European countries except Turkey; ruthless slaughter is the only remedy. Owing to study and experimental research a method of preventing animals contracting the disease has been discovered, "and the benefits derived from anti-rinderpest serum are recognised in every country where the disease has appeared since the method was introduced."

Actinomyces.

Actinomyces is a widespread disease amongst cattle, and not uncommon in man. There have been seven cases in the Royal Infirmary during the last four years. The infecting agent is a special type of bacterium called a streptothrix, which usually attacks the mouth of cattle, and is probably communicated by their food. It is doubtful, however, whether *man* can be infected by eating flesh or drinking milk from a diseased animal. There is much need of further research.

Equine Influenza.

This is a terrible disease of horses which ravaged Europe in 1881, and North America in 1900. Though the mortality is usually low, it may reach 90 per cent. Animals which recover are often unable to work for months afterwards. "Our knowledge," says the most recent text-book, "of the bacteriology of this disease is imperfect and uncertain."

Pink-eye in horses seems to be allied to influenza. Serious outbreaks occurred in Liverpool in 1890, 1900 and 1906, draught horses being specially affected. It has threatened to hold up the trade of the port. Large numbers of animals succumbed. Thus one owner lost 8 out of 16, another 11 out of 38 (Daily Press). The complications of pink-eye are most serious. Practically nothing is really known of its cause, prevention, or cure.

Canine Distemper.

We are all familiar with the distemper of dogs, how it especially attacks puppies, and destroys from 20 to 70 per cent. The house dog is particularly liable to the disease; so are pointers, greyhounds, pugs, poodles, and spaniels. The germ of distemper is unknown. Some attribute it to this or that bacterium; numbers have been "discovered"; others believe the virus is ultramicroscopic.

The prevention and treatment of distemper is unsatisfactory. The man who discovers a reliable vaccine or serum will save the lives of thousands of valuable dogs.

Other Infective Diseases.

I have said nothing of louping ill, so common amongst Scottish sheep, due to an unknown virus carried by a tick; of sheep pox, an almost incurable disease; of that terrible plague pleuro-pneumonia which cost this country from September 1890 to the end of 1898, when it was finally stamped out, in compensation for slaughtered cattle, £357,626; of the tropical affections in cattle like Texas and East Coast fever, both of which seriously affect the economic conditions of the country.

I have said nothing of infective diseases in birds, as fowl cholera, which causes enormous losses, though protective inoculation is sometimes satisfactory.

I have said nothing of sheep scab, and foot rot, or of the comparatively insignificant disease, parasitic mange, which, nevertheless, according to a report recently compiled by Mr. Pillers, for Mr. Eaton Jones, caused a loss amongst Liverpool horses last year of 7,420 working days—equivalent to some £1,810.

The point I wish to emphasis is this: though we know something of the cause, or prevention, or cure of certain infectious diseases of animals, there are many others about which we are still completely ignorant.

DISEASES APPARENTLY NOT DUE TO BACTERIA OR OTHER PARASITES.

Let us now consider a group of diseases affecting man and the domesticated animals which, so far as we know at present, are not due to bacteria or other parasites, or, at any rate, are not infectious in the ordinary popular sense of the word.

Malignant Disease.

Cancer and other forms of malignant disease are the most important of this group.

(*a*) An inaugural lecture delivered before the University of Liverpool on Friday, February 21st, 1913.

King Edward. I think, said that the man who discovered the prevention or cure of malignant disease deserves a monument in every European capital.

It has been stated that among those above the age of 35 now living, the chance of ultimately dying of cancer is one in seven for women, and one in eleven for men (Bashford, 1908). According to the registrar's returns, 34,607 persons died of malignant disease in England and Wales during 1910. The number of cases *recorded* each year is steadily increasing.

An enormous amount of research is being conducted at the present day on the cancer problem. There are special cancer institutes in Europe and America. In England we have the Imperial Cancer Research, and the special researches at the Universities of Glasgow and Liverpool, the latter under the charge of Dr. Wakelin Barratt.

Ten years ago little was known about malignant disease in wild or domestic animals, but now we have discovered that it is universal in all races of men and in all vertebrate animals.(*a*) It may occur in the horse, the sheep, the pig, the elephant, the rat, the dog, the hen, and even the trout and the cod. The discovery of this broad zoological distribution of cancer amongst men and animals has been of great value in leading to a complete change in certain aspects of the cancer problem, by effectively disposing of many speculations regarding its origin.

We have learnt much from the study of cancer in mice, who are particularly susceptible to it. We have found that cancer is capable of being transplanted from mouse to mouse—a fact of great scientific value. Further, mice can be protected from developing experimental cancer by a form of vaccination, as cattle are protected by vaccination against anthrax. It is quite possible that some day this principle of protective inoculation may be applicable to the prevention or treatment of malignant growths in man.

The cancer problem stares humanity in the face. It can only be solved by research, by experiment, and by studying the disease as it affects both men and animals. Remember Hunter's advice to Jenner which led to the discovery of vaccination for smallpox—do not think, try.

Other Diseases.

I do not wish to weary you with a description of other diseases in this group, of which our knowledge is still incomplete, as roaring, for example. This disease has recently incapacitated a valuable animal, Jerry M., engaged to run in the Grand National.

Animals, like men, die from heart disease, pneumonia, gastric ulcer, and apoplexy; they may suffer from nerves, become epileptic or insane; even neurasthenia has been described in sheep (James Law, vol. iii. p. 181). But omitting certain infectious diseases, such as whooping cough, etc., so far as I know, the human race still demonstrates its superiority over "the beasts that perish" by enjoying a monopoly of appendicitis and hysteria!

Anyone familiar with scientific research is aware that progress in any particular branch is, in no small measure, due to study and to comparison with other branches of science. Thus our knowledge of human anatomy, human physiology, human bacteriology, human surgery, has been greatly extended by a comparison with our knowledge of similar subjects in the lower animals.

I wonder how many medical men realise that the domestic animals may be affected with those three strange human diseases, lymphadenoma, leucocythæmia, and diabetes, of which we know comparatively little.

I have shown that owing to study and research we now know something of the cause, prevention, and cure of many animal diseases, but we are still profoundly ignorant of others. Past experience demonstrates that further study and research will certainly extend our knowledge, and therefore benefit both the animal and the human community.

(*a*) Neoplasms were found in 162 out of 67,849 bovines slaughtered in Great Britain in 1910. The Imperial Cancer Research examined 168 neoplasms microscopically: 120 proved to be cancer, and 29 sarcoma (Trotter, *Journ. Comparative Path. and Therapeutics*, vol. xxiv. p. 1).

PART II.

NUMBERS AND EDUCATION OF THE VETERINARY PROFESSION.

The amount of disease in the domestic animals, and therefore, to some extent, the amount of disease in man, must partly depend upon our knowledge of veterinary medicine and surgery, and upon the numbers, ability, enthusiasm, and scientific training of the members of the veterinary profession.

Veterinary Profession Undermanned.

Let us first consider the question of numbers. Obviously, if the veterinary profession is undermanned the whole community suffers. Official figures show that the average number of men entering the veterinary profession in the last five years, viz. 1907 to 1911, was only 85, compared with an average of 140 during the preceding five years. In Great Britain the output of veterinary surgeons is only one to every half million inhabitants, but in Germany one to every 210,000, in France to every 300,000, in Denmark to every 133,000, and in the United States to every 120,000 inhabitants.(*a*)

The reasons for this diminution in the number of men entering the profession are numerous. The veterinary surgeon is not properly appreciated by the man in the street, the farmer, the public bodies, and the Government, partly, perhaps, because he is not so well trained as his medical brother.

But there is another reason, viz. the advent of mechanical traction. The impression is general, that as the horse is disappearing from the streets, the necessity for the veterinary profession is disappearing with him. This impression is absurd, for many reasons, but I will only mention one now: not only will enormous numbers of horses be employed in agriculture for many years to come, but horse breeding for exportation is a great industry. Thus in 1911 the declared value of British and Irish horses exported abroad was 1½ million pounds.

The diminution in the number of veterinary students has become so serious that the Government, beginning to realise the importance of veterinary medicine, appointed a Departmental Inquiry, which reported last month.

The report states that the number of suitable candidates for appointments in all the public veterinary services, with one exception, the Army, is *inadequate*. These public services are described as follows:—

1. *The Indian Civil Veterinary Department*, whose principal duties are concerned with—
   - (*a*) Educational work in veterinary colleges;
   - (*b*) Horse and mule breeding;
   - (*c*) Cattle disease and cattle breeding;
   - (*d*) Veterinary research.
2. *The Colonial Veterinary Service*—
   - (*a*) For the Crown Colonies and Protectorates where the work is of an exceptionally difficult character, and diseases unknown to this country have to be studied, and if possible suppressed; and precautions ought to be taken also to prevent the introduction of new diseases into the colony.
   - (*b*) The Colonial Veterinary Service in the self-governing Dominions. In Canada the principal work undertaken here is in connection with the veterinary inspectors, stationed at abattoirs, the quarantine of animals, the control of diseases already existing. In South Africa the supply of men for executive and advisory work is "inadequate." In Australia and New Zealand meat inspection and the quarantine of livestock is the principal work. "In New Zealand the supply of well-trained veterinary surgeons is

(*a*) This information has been received from authentic sources and supplied to me by Mr. Share Jones.

insufficient, largely, no doubt, *because there is not adequate provision in the United Kingdom for them to obtain special instruction in meat inspection*" (italics mine).

3. *The British Board of Agriculture and Fisheries*, whose officers diagnose and report upon the various diseases which are the subject of legislation and conduct research and experimental investigations.

4. *Veterinary Surgeons*, acting as
   (*a*) Local veterinary inspectors of the Board of Agriculture, employed in connection with the outbreaks of swine fever, etc.
   (*b*) Veterinary inspectors appointed by the Local Authorities under the Diseases of Animals Act.
   (*c*) Qualified veterinary medical men employed by the Local Authorities under the Public Health Acts.

The Parliamentary Committee made several recommendations with a view to increasing the output of veterinary surgeons and raising the standard of their training. We see, therefore, that the properly qualified veterinary surgeons will have little difficulty in finding appointments which offer a more permanent income than private practice. About 50 per cent. of our own students hold at present such appointments.

The British method of meat inspection is typical of our want of appreciation of the value of veterinary work. There are only about 50 whole-time veterinary inspectors of our meat supply. The United States has 775, and Germany 1,180—in this country every carcase is inspected and stamped. Our veterinary inspectors, with their haphazard methods, sometimes catch the butcher selling infected meat, but more often they do not; instead, the public catch the infection!

"England," says Ostertag, the great German expert, "which is otherwise so well organised with regard to sanitation, and which is called the 'cradle of hygiene,' is entirely without regulated meat inspection."

You may be interested to know that there is organised meat inspection not only in Belgium and Germany, but in Spain and Roumania. The conspicuous exceptions are England and Turkey!

But, apart from the inadequate supply for the public services, there is no reason to believe that the veterinary surgeon cannot obtain work in private practice. Figures recently received from the largest veterinary transfer agency show that the takings in six out of seven practices for sale have increased during the last three years.

There is great hope for the future. The growing recognition by the public of the importance of veterinary subjects, particularly of preventive medicine; the education of the farmer in the value of expert advice on questions of food and stock breeding; the possibility of an organised system of meat inspection, and also of animal insurance, which is adopted in France, Switzerland, and Belgium, and assisted by the State subsidies—all brighten the outlook of the veterinary profession.

Preliminary Scientific Training.

I must now direct your attention to the second section, viz. veterinary *education*, and shall divide it into two parts—the preliminary scientific training and the clinical training.

I intend to confine my remarks to Liverpool, because we have a young and vigorous veterinary school at our University. It was established in Liverpool in 1904, partly owing to the initiative and energy of Sir Rubert Boyce. Though still in its infancy, 58 students have obtained a diploma of the Royal College of Surgeons, and 21 the diploma of Veterinary Hygiene, while it can boast of 65 postgraduates.

Our veterinary school has one unique advantage unenjoyed by any of the four other schools in the United Kingdom—it is not a separate college, but is part of the University, *i.e.*, intramural, and its students attend classes in the University. There are several advantages in such a system.

Firstly, the student enjoys the admitted privileges of a University education and environment; they have the advantage of coming into contact with men working in other departments of science and art, and of participating in the social functions of the University.

Secondly, the preliminary scientific training of the veterinary student occupies about two of his four years, and of the medical about two and a-half out of five. It is the foundation, upon which the superstructure of all their professional knowledge is built, and that foundation must be "well and truly laid."

One of the most unsatisfactory features of the curriculum in almost all the London medical schools and all the veterinary colleges, except our own, is the impossibility of providing proper laboratories and staff for the teaching of the preliminary scientific subjects on account of the great expense involved.

Our veterinary students, however, have all the resources of the University at their disposal; its well-equipped laboratories, and its large and efficient staff, for teaching these subjects—as zoology, physics, chemistry, and physiology. The Departmental Report pays a high tribute to the Liverpool system by stating, "it would probably be desirable that similar arrangements should be adopted at the other teaching centres."

Lastly, our veterinary students have the advantage of studying some of their professional subjects, such as general pathology, bacteriology, and toxicology with the medicals, and they are just as keen.

Unfortunately our school is greatly in need of money to endow chairs and establish its teaching on a firm basis. It also needs money for the prosecution of research.

The veterinary schools abroad, where the value of scientific education and research is better recognised, are State-aided, and monumental works on veterinary subjects are being produced by men like Moller and Cadiot in surgery; Chaveau, Ellenberger, and Baum in anatomy; Bang, Nocard, and Arloig in pathology and bacteriology; and Neumann in parasitology.

One of the witnesses at the recent Departmental Inquiry on Foot-and-Mouth Disease described the lack of scientific research in this country upon animal disease as a "disgrace to a great nation."

Clinical Training of Veterinary Students.

Let us now turn to the second and more important part of the student's career. His clinical training, viz. the method of giving and instructing him practically in the diagnosis and treatment of animal diseases.

In order better to appreciate the present position, I will compare his clinical training with that received by the medical student. The medical student is compelled by law to obtain his practical knowledge of disease in the wards of a certain number of officially recognised large general voluntary hospitals, which are intimately connected with the medical school.

Such hospital training is the most vital part of the student's curriculum both in Europe and America.

The advantages of this training in a large general hospital are enormous, both to the teaching staff, the students, the patients, and medical science generally.

1. The teaching staff acquires much experience in studying large numbers of patients; they have the advantage of the advice of their colleagues, and of the assistance of experts in other branches, such as pathology, bacteriology, radiography, etc.; while the presence of the medical student is a constant encouragement to them in their work, and a stimulus to keep up to date.

2. The students profit, for they are taught by men of large experience, and more clinical material is available, which is co-ordinated into one or two buildings.

3. The patients have the advantage of being treated by the best medical men in the town, with the widest experience, and assisted by many specialists. Besides the wards, operating theatres and other buildings are more efficient and modern in a teaching hospital. There is not the slightest doubt that the whole standard of the hospital is raised owing to the presence of the medical students.

Working out the figures given in Burdett's *Hospital Annual* for 1908, I find that 71 general hospitals unconnected with medical schools, representing 8434 beds, cost only £80 per bed, but 31 general hospitals attached to medical schools cost £118 per bed. Thus, broadly speaking, a patient at a medical school hospital has £38 extra spent upon his treatment per annum (*a*).

If, ladies and gentlemen, it were possible for a Liverpool University professor to fall upon evil days, and become an in-patient in the public ward of a general hospital, I personally should not hesitate to choose one attached to a medical school, even though there was a serious risk of some of my *corpus vile* being carefully preserved in spirit on the shelves of the medical school museum.

4. Lastly, we must not omit to mention the enormous debt every branch of medicine owes to the study of disease in hospitals.

The dental student is also taught his clinical work in a voluntary hospital, where all the material is concentrated and co-ordinated.

Necessity of an Animal Hospital.

The eminent army veterinary surgeon, Major-General Smith, last year alluded to the differences between the clinical education of a veterinary and a medical student. "The medical school," he said, "went to the hospital in order to be able to utilise its clinical material for teaching; a school without a hospital is inconceivable." We have a splendid example of this in Liverpool, for the Royal Infirmary, established in 1745, was rebuilt on its present site in 1824; ten years later the medical school was founded, which eventually developed into a University College, and so became the ancestor of the University of Liverpool.

According to General Smith, "public hospitals for animals are unknown." (*b*) "Our schools," he says "have been created, but the question of where the clinical material may come from has largely been left to chance."

There is, however, a hospital for animals in each of the four veterinary colleges, London, Edinburgh, Glasgow, and Dublin, where students acquire some clinical experience, but these institutions are not all that could be desired.

I must not omit to mention the valuable work which the Royal Society for the Prevention of Cruelty to Animals is at present doing in this city, with the assistance of veterinary surgeons, by providing dispensary, not hospital, treatment for selected cases of sickness among the animals of the very poor. There are, however, no in-patients, and there is no operating theatre, and, further, it is a dispensary from which cattle, dogs, and cats are excluded.

In Liverpool clinical teaching has been organised on different lines. The City Corporation and also our veterinary teachers very kindly permit the students to attend the clinics at their own private hospitals, which are situated in different parts of the town, and there they acquire much valuable experience. Nevertheless, I am personally convinced that if our veterinary school is to be established on a sure foundation it must possess a hospital of its own, situated as close to the University as possible.

Some may ridicule the necessity of a hospital for animals. Time was when the necessity of hospitals for human beings was also ridiculed.

I think some of the essential features of the scheme are the following:—

1. The buildings must contain besides pens, stalls kennels, etc., a thoroughly equipped modern operating theatre, as perfect in detail as those used for human patients. There are five operating theatres in the Royal Infirmary. The veterinary school of Melbourne, Australia, has recently been presented by Mr. Cuming with a magnificent operating theatre equipped with all the modern scientific appliances. Remember what a debt human surgery, particularly abdominal surgery, owes to operations first practised upon the lower animals. (*a*)

The buildings must also contain an X-ray apparatus. The value of X-rays in diagnosis and treatment of human disease is enormous. Aldershot is, I believe the only place where there is an X-ray department for animals in the whole of the United Kingdom. How useful it would be, for example, in the diagnosis of spavin, ringbône, splints, and other equine diseases.

The buildings must contain a clinical laboratory.

2. The hospital must be situated as near the University as possible, if not within its precincts. (*b*)

3. The hospital would partly be maintained by voluntary contributions, and animals of the very poor would be treated free. There is many a man in this city whose horse or ass is the family breadwinner, and when sickness comes he is unable to pay for proper treatment, still less to feed the animal during its illness. *The strictest precautions must be taken to prevent hospital abuse.*

4. Of course, the hospital would not be licensed for experiments on animals, but strictly limited to the study, diagnosis, and treatment of animal disease. (*c*)

I am convinced that such a hospital, stamped with the seal of University approval, conducted on broad and scientific lines, would be a credit to the University and the city, and soon establish not merely a local but a national reputation.

Veterinary surgeons would send to its clinic patients requiring serious or difficult operations, patients in need of special treatment, patients suffering from obscure or unknown diseases, patients requiring investigation by microscopical, bacteriological, or chemical methods, patients with diseases suitable for teaching, patients with diseases apparently incurable.

Such a hospital would confer enormous benefits

(*a*) These figures are calculated on the combined ordinary and extraordinary expenditure, and make no allowance for unoccupied beds or out-patients.

(*b*) Manchester Veterinary Association, July 24th and 25th, 1912.

(*a*) [*Note.*—The late Mr. Lawson Tait, many years ago, stated that surgery had not derived benefit from animal experiments, and Dr. Bentock, another of the older surgeons, is of the same opinion.

Sir Frederick Treves, although he said in 1898 that his "operations upon the canine bowel . . . had done little but unfit *him* to deal with the human intestines," wrote in a letter to *The Times* of April 14th, 1902, regarding this very statement: "The fallacy of vivisection can hardly be said to be established by *the failure of a solitary series of operations dealing with one small branch of practical surgery* (italics mine). No one is more keenly aware than I am of the great benefits conferred upon suffering humanity by certain researches carried out by means of vivisection."

There is not the slightest doubt that the majority of the medical profession recognise that human surgery owes a debt to experiments first practised upon animals. I may mention specially Lord Lister (*ipse dixit*), Sir William Osler, Sir Victor Horsley, Sir Henry Morris, Sir H. Swanzy, and the celebrated American surgeons, Halstead and Harvey Cushing.

The following are some of the surgical "operations *first praetised* on the lower animals" . . . "to which human surgery owes a debt."

(1) Operations upon the brain, which have led to "the localisation of the motor centres in relation to brain abscess, brain tumours, and brain injuries, and to the operation of trephining brain tumours" (Sir Henry Morris).

(2) Certain operations upon the gall-bladder by M. Herlin and M. L'Anglas.

(3) Certain operations upon the larynx by V. Czerny.

(4) Extirpation of the kidney by Zambeccarius in 1670 and Roonhuyzen in 1672, and "several others in the beginning of the nineteenth century."

(5) Abdominal surgery particularly indebted to operations upon animals by Barischewsky, by Lembert, by Travers, by Gussenbauer and Winwarter.

A Liverpool surgeon, whose reputation for abdominal surgery is so wide that he is at present contributing a chapter on the subject to an American text-book, told me that before first performing a certain new and original, and now widely practised operation upon the human intestine, he tested the value of his method and improved his *technique* by first operating upon living animals. He also wished that he had adopted this practice in certain other operations.]

(*b*) The hospital should be near the University, first, in order that the veterinary students should not waste time by daily walking long distances between the University and the hospitals; secondly, that the animals should have the advantages of the University laboratories for the diagnosis of their diseases by microscopical, bacteriological and chemical methods, as the patients in a human hospital. I know from actual experience that such work is more efficiently performed if the hospital and the laboratories are adjacent to one another. I want animal patients to have the same advantage as human patients.

(*c*) It is necessary to state that I, in company with many other medical or veterinary men, would strongly oppose ever licensing the animal hospital for vivisection, just as I would oppose licensing a human hospital like the Royal Infirmary. Apart from this, it is extremely unlikely that the Government would license any additional premises in Liverpool. Of course scientific men in Liverpool would not think of attempting to practise vivisection in unlicensed buildings.

upon the animal community, and its association with the veterinary school would raise the whole standard of treatment, as obtains with hospitals attached to medical schools.

It would firmly establish the veterinary school and greatly improve veterinary education, by increasing the number of cases available for teaching purposes and by concentrating and co-ordinating them in one building adjacent to the University.

The staff would also have the advantage of a widened experience, of consulting with their colleagues in difficult cases, and of the assistance of an expert pathologist, bacteriologist, and radiographer; while the University laboratories would be close at hand for special diagnosis work by microscopical, chemical, or bacteriological methods, for the preparation of autogenous vaccines used in treatment, and research.

The hospital would attract to its clinic the busy veterinary practitioner and the post-graduate student; it would lead to a better organisation of research in all branches of veterinary medicine and surgery.

Of course, there are very many difficulties that must be removed before such a hospital can be established. They are mainly financial, and I am convinced they are not insuperable.

Love of animals is a British characteristic. We are the most humane nation in the world, and the first I believe, to found the Society for the Prevention of Cruelty to Animals. We have abolished cock-fighting, bear and bull baiting, the cropping of dogs' ears, and the dishorning of cattle, yet, says General Smith, "public hospitals for animals are unknown."

Summary and Conclusions.

1. Man first began to domesticate animals in the Neolithic age. He is indebted to them for both necessities and luxuries; they are partly responsible for his present civilisation.

2. Men and animals are to a large extent subject to the same diseases. An increasing number of infectious diseases are recognised as being frequently communicated from animals to man.

3. Animal diseases produce a considerable amount of suffering in animals themselves, and they also seriously interfere with man's necessities and luxuries.

4. Thanks to study and research, we now know something of the causes, prevention, and cure of many animal diseases, but we are still profoundly ignorant of others. Past experience demonstrates that further study and research will certainly extend our knowledge, and therefore benefit both the animal and the human community.

5. The study, prevention, and cure of animal disease largely depends upon the numbers and efficiency of the veterinary profession.

6. There has been a serious diminution in the number of veterinary students during the last five years, partly owing to a want of public appreciation of the value of veterinary science.

7. The Government, at last realising the serious position of affairs, has issued a report stating that the supply of men for the public services is deficient, and steps will, no doubt, be taken to remedy this deficiency.

8. In spite of the advent of motor traction, the demand for properly trained veterinary surgeons in private practice also will probably increase, rather than diminish.

9. At this psychological moment it is well to remember that the University of Liverpool possesses a young veterinary school, which is superior to the others in the United Kingdom, as regards its preliminary scientific training. The students, further, have the advantage of a University education.

10. The clinical training of our veterinary school, however, is not the best possible, in spite of the able assistance of its clinical teachers. It does not, like our medical school, possess the advantage of a hospital near the University with a modern operating theatre, an X-ray department, etc., where diseases can be studied, diagnosed, and treated by the most modern methods.

11. Such a hospital would benefit not only the domestic animals—especially those belonging to the poor—but also the students, the teachers of the school, and the veterinary profession generally. It would increase our knowledge of both animal and human disease.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Operation for Goitre under Intra-tracheal Administration of Ether.—Mr. Carless operated on a woman of middle age who had been suffering for some time from goitre, which caused great interference with her breathing. She had been attending the throat department for some time on this account, and was transferred from it to the surgical department. The goitre at first was small, but apparently last summer it suddenly became enlarged and painful, evidently the result of some inflammatory trouble; this was accompanied by considerable respiratory embarrassment. In time, however, the swelling diminished, and when admitted to hospital there was but little enlargement of the thyroid body. The patient complained much of difficulty of breathing, especially at night, and on laryngeal examination it was found that the trachea was compressed and narrowed. The diagnosis that was made was either a simple goitre, evidently sclerosed as the result of inflammation, or malignant disease. On careful examination, however, the surface of the gland was smooth and free from nodules, no enlarged glands could be felt, and there were no obvious adhesions to the superficial tissues. The voice was husky, and the movements of the right cord were defective.

The patient was anæsthetised by Dr. Silk by means of A.C.E. mixture, and then, the mouth being gagged open, a cannula, equal in size to No. 20 catheter, was passed through the glottis down the trachea, and ether vapour pumped through this into the lungs, the vapour having first been warmed by passage through warm water. Anæsthesia was easily maintained throughout the operation. The incision used was in the middle line extending from the pomum Adami down to the episternal notch. The muscles on either side were separated and retracted, and the thyroid body exposed. It was found that the right lobe was mainly involved, and was represented by a hard mass closely fixed to the trachea and, indeed, extending almost round it. Removal of this half of the thyroid body was then undertaken; the vessels passing to and from it above and below were secured just outside the capsule, and the isthmus was cut through in the middle line. It was a matter of some little difficulty to detach the thyroid body from the trachea, to which it was very closely adherent, and several vessels had to be secured on deep side. After removal of the thyroid body the trachea appeared to be of normal size and shape, and had evidently plumped out when pressure had been relieved. Enlarged lymphatic glands were looked for, but none were found. Hæmostasis having been effected, the muscles and fasciæ were drawn together by deep sutures, and a small drainage tube was inserted. The cutaneous incision was closed in the usual way.

Mr. Carless commented on the difficulty of diagnosis in this case owing to the small size of the thyroid swelling. When the patient was sitting in the erect posture very little abnormality of the neck could be detected, and it was only when she threw her head far back that one could realise a tumour being present at all. The history, he said was perfectly clear as to the existence at an earlier date of a thyroidal swelling, which had at one time become rapidly enlarged. As the swelling gradually became reduced in size respiratory trouble became more and more marked, and thus it was evident that some condition was present which was leading to pressure on the trachea. Some form of cancer of trachea without a large amount of fibrous tissue would constitute a very small tumour, but the absence of glands of nodulation and of extensive adhesions negatived that diagnosis. The defective

movement of the right vocal cord was in favour of a malignant diagnosis. The section of the portion removed was of a somewhat indeterminate character, and no opinion as to its nature was ventured till a microscopic report could be obtained. Mr. Carless also commented favourably on the administration of ether by intra-tracheal intubation in such a case as this. It was impossible, he remarked, to know how much damage the trachea had sustained from pressure, and the possibility of its collapse, or even of wounding it, could not be overlooked. The passage of the cannula beyond the pressure zone relieved the surgeon's mind of any anxiety in this direction, and by insuring a sufficiency of ether and air without reference to the position of the patient's jaw kept the anæsthetist's hands away from the neighbourhood of the wound and protected the patient from the possibility of infection from this cause.

ROYAL LANCASTER INFIRMARY.

TUMOUR OF CÆCUM.—Before operating, Mr. A. S. BARLING said: The patient on the table, a woman of 66, has suffered from pain in the abdomen with alternating constipation and diarrhœa for the last three or four years. Two years ago she had a laparotomy done in a hospital at Liverpool, where she then lived, and she was told that she had a large cancer of the bowel, which it was not considered safe to remove. Since then she has lost much weight, and a hard swelling has appeared in the cæcal region. For the last few months there has been increasing difficulty in getting her bowels to act, until now she is suffering from total obstruction of four days' duration. She has been vomiting duodenal contents, and, as you see, her condition is very grave. There seems little doubt that she is the victim of cancer, and we shall most likely have to do an ileo-colostomy.

The abdomen was then opened through the edge of the right rectus, and a tumour, three inches in diameter and eight in length, was found growing from the inner wall of the cæcum and blocking the ascending colon. It was not attached except at its base. The patient's state did not admit of any severe operation, so an anastomosis was rapidly made between the ileum and the transverse colon, and the patient left the theatre little the worse. She made an uneventful recovery, and left the hospital in a month much relieved. She was advised to come back in a few weeks' time to have the tumour removed, but has not done so. Her medical attendant says that she is so much better that he cannot prevail upon her to have anything further done. The operator said that he had only seen a few cases of simple tumour of the intestine, and he thought that they were rare. As there had been several attacks of bleeding from the bowel in the present case, he considered it likely that the tumour was a papilloma.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD DECEMBER 12th, 1913.

Dr. LEONARD GUTHRIE in the chair.

DISCUSSION ON ENLARGEMENT OF THE SPLEEN IN CHILDREN

(Opened by Robert Hutchison, M.D., and Sir John Bland-Sutton, F.R.C.S.)

Dr. HUTCHISON suggested the following grouping of enlargements of the spleen met with in children in this country.

1. Tumours.—Neoplasms, endothelioma, cysts, etc.
2. Infective.—Typhoid, ulcerative endocarditis, malaria, tuberculosis lymphadenona, chronic arthritis.
3. Chronic venous congestion.
4. Metabolic disorders.—Rickets, lardaceous disease.
5. Blood diseases.—Leukæmias, splenic anæmia of infancy, chloroma, congenital anæmia with splenomegaly and jaundice.
6. Splenic anæmia of the adult type.
7. Syphilitic.
8. Splenomegaly with acholuric jaundice.
9. Splenomegaly with cirrhosis of liver.—(*a*) Portal cirrhosis, alcoholic and other forms; (*b*) biliary cirrhosis; (*c*) syphilitic cirrhosis; (*d*) Banti's disease; (*e*) congenital obliteration of bile-ducts.

Dr. Hutchison pointed out that the classification was mainly a clinical one. He then made a few remarks explanatory of each group. With regard to group 5, he pointed out that chronic myeloid leukæmia, which causes so great a degree of enlargement of the spleen in adults, is a rare disease in childhood, but acute myeloid and lymphatic leukæmia are not very uncommon and are attended by a considerable degree of splenomegaly. By far the commonest blood disorder in early childhood, characterised by marked enlargement of the spleen, is the so-called pseudo-leukæmia of von Jaksch (splenic anæmia of infancy). The pathological problems which arise in connection with enlargement of the spleen in these cases in children do not differ from the kindred problems which arise in the case of adults. Group 6:—Cases are sometimes met with in later childhood which are indistinguishable from the splenic anæmia of adults. Group 9:—Enlargement of the spleen with cirrhosis is not infrequent. Several varieties may be distinguished. (*a*) The cirrhosis may be of the multilobular type; some cases are alcoholic, but probably other poisons produce a similar result. (*b*) The cirrhosis may be of the monolobular variety (Hanot type). (*c*) The cirrhosis may be syphilitic. (*d*) Enlargement of the speen may exist for years and be followed by a multilobular cirrhosis (Banti's disease). (*e*) Cirrhosis may depend upon congenital malformation of the bile ducts.

As regards pathology, (*a*) what is the cause of the enlargement of the spleen? (*b*) What is its relation to the pathology of the disease as a whole? and especially is the spleen playing an active or passive part? It is reasonably certain that the cause of the enlargement is not the same in all the groups, but it is particularly necessary to enquire what part is played by syphilis in its production. Dr. Hutchison suggested that in groups (6) and (8) syphilis plays no part, and not in cases of cirrhosis except where the cirrhosis is of the well-known syphilitic variety. As to the ultimate cause of the enlargement in acholuric jaundice, in splenic anæmia of the adult type, in portal and biliary cirrhosis and congenital obliteration of the bile-ducts he had no suggestions to offer. The results of splenectomy are now enabling one to say whether the part played by the spleen is active or passive. In groups (6) and (8) the spleen is in some way the cause of the other features in the clinical picture.

As regards therapeutics he suggested that splenectomy is indicated in groups (1), (6) and (8). It will generally be admitted that it is entirely inadmissible in group (5).

Sir JOHN BLAND-SUTTON first discussed the functions of the spleen. He pointed out the rapid increase in size after birth, and the facility with which it becomes engorged in fevers and other infantile disorders, especially rickets, suggests that it has important functions at the commencement of life. The enlarged spleen associated with numerical reduction of the red corpuscles in the disease of children known as splenic anæmia is due to functional over-activity of the spleen. When its destructive activity is excessive, harmful products of this over-action accumulate in the blood, producing, in addition to anæmia, acholuric jaundice. He had removed the spleen of a young woman, æt. 22, for acholuric jaundice with a most satisfactory result. In children the spleen can certainly be removed without interfering with their growth and development. Removal of the spleen in

children suffering from splenic anæmia is a life-saving measure.

In 1895 he excised the spleen from a girl, æt. 5, for splenic anæmia. Sutherland and Burghard's patients were aged 6 and 12 years respectively. Hutchinson removed the spleen from a boy æt. 7. Makins removed the spleen from a girl æt. 9. He (Sir John) removed an enormous spleen from a girl, æt. 17, suffering from splenic anæmia and jaundice. In all these cases the result of the operation was a complete success.

He recommended opening the abdomen in the left linea semilunaris. The suspensory ligament (phrenocolic) is then snipped with scissors, and the spleen then slips out quite easily. The vessels are secured with hæmostatic forceps and divided with the gastrosplenic omentum close to the spleen. After the organ has been excised the vessels are tied with silk.

He then emphasised the importance of a study of the microscopic features of the blood when there is enlargement of the spleen. To-day any abdominal swelling resembling an enlarged spleen suggests a blood count, and he is an unwise surgeon who removes a spleen before making a microscopic examination of the blood. The removal of a leukæmic spleen always ends in disaster.

Dr. G. A. Sutherland pointed out that at one time "primary" diseases of the spleen were not recognised. At the present time, instead of there being no recognised primary diseases of the spleen it would appear that the number of them is increasing, as judged by the results of splenectomy for the relief or cure of various clinical phenomena. Here, as in other cases, surgical procedures have gone ahead of pathological knowledge, for it is not yet known what the exact nature of the splenic disease has been.

Dr. Sutherland then gave an account of two cases of splenic anæmia which had been under his care in each of which Mr. Burghard had performed splenectomy. In each of these two cases the splenic anæmia was a family affection. In each case there was a rapid improvement and eventually a complete cure. Dr. Sutherland pointed out that in splenic anæmia the splenic vessels are enlarged, and that this has usually been ascribed to the call of the spleen for more blood. On the other hand, it is possible that there may be primarily a pathological condition of the splenic vessels, a vaso-motor disorder, leading to hyperæmia of the spleen, and that its natural functions are thus disturbed.

Dr. Poynton limited his remarks to cases of family acholuric jaundice. He had four families under observation, including 12 individuals, some of which had been under observation for some years. He believed that he was among the first to point out in this country that the condition of yellowness might alternate with that of anæmia, and that an enlarged spleen with an anæmia so little tinged with a yellow colour as to be easily overlooked might occur in some members of these families. He had not yet had a case operated upon, although in one case he had recently advised it. The diagnosis was full of difficulties and they were interesting ones. Gall-stone colic, gastric ulcer, intussusception, and renal colic had been among those made in his cases. Syphilis of the liver, splenic anæmia, chlorosis, and Addison's disease were other diagnoses that had been made in his comparatively small collection.

Dr. Thursfield said that the type of disease known as splenic anæmia was really a congeries of cases due to different causes. From that group there had been separated off the group of acholuric jaundice. But even that was not a homogeneous group. The causation remained obscure, though it was certainly not syphilis. With regard to the pathology of the various cirrhoses he did not think that any advance had been made. At present there was no method by which one could examine the blood of the living patient and demonstrate the hæmolysins causing the anæmia or the pigmentation as the case might be. Still he did not despair of some such method being found. With regard to the fragility of corpuscles there was no abnormal fragility in any disease, even in purpura hæmorrhagica and scurvy, except in acholuric jaundice, where in 12 cases, with one exception, the fragility was abnormal. He felt that in these obscure cases, when the patient was not making satisfactory progress, a surgeon should be asked to remove the spleen, especially because he believed that in the vast majority of cases of splenectomy the whole of the splenic tissue was not removed.

Mr. Philip Turner mentioned a case of a boy, æt. 5, whose spleen he had removed. He was very wasted, the skin had a yellow waxy appearance, the spleen was much enlarged, filling the left iliac fossa. Anæmia was intense, red corpuscles being 1½ million and hæmoglobin 25 per cent. Dr. French, under whose care the child was, had diagnosed von Jaksch's anæmia. In spite of all treatment the child got steadily worse, and removal of the spleen was decided upon. The operation, which was carried out on the lines described by Sir John Bland-Sutton, was attended by very little shock and but little blood was lost. The result was remarkable. Within three months he was practically well.

Dr. T. S. Lukis discussed the question of the fragility of the corpuscles. Mention had been made of the vital staining granules which he had been studying for some time. His researches were not complete and his conclusions had not been formed. Still, it seemed clear that, whatever these granules were, they bore a definite relation to blood destruction, and particularly to blood regeneration. One found them in cases which had surgical hæmorrhages; they appeared in the blood for a time during regeneration, and disappeared when the blood returned to normal.

In 7 cases of acholuric jaundice which he had examined he found a very high percentage of these vital staining cells. He had also examined these cells in cases of von Jaksch's anæmia, pernicious anæmia, and leukæmia. Generally speaking, in these cases where there was a high percentage of vital staining cells the prognosis was better.

Dr. Parkes Weber suggested that the word abnormality might be substituted for enlargement of the spleen. He thought that with the help of further research the following classification might be possible:

1. Enlargements of the spleen in which the enlargement and structural or functional change was serving some useful purpose.
2. Enlargements due to the presence of tumours.
3. Enlargements, or alterations due to the local presence of microbes.
4. Enlargements or alterations connected with disorder or excess in the functional activity of the splenic tissue.

Dr. Hutchison and Sir John Bland-Sutton then replied.

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, January 29th, 1914.

President, Mr. Jackson Clarke, in the Chair.

Exhibition of Clinical Cases.

The following clinical cases were shown:—Dr. W. H. Willcox: (1) A case of Raynaud's Disease; (2) Tracheotomy after poisoning with glacial acetic acid; (3) Aneurysm of the Arch of the Aorta; (4) Pituitary Tumour.

Sir John Broadbent: (1) Splenomedullary leukæmia; (2) Friedreich's ataxy associated with congenital heart disease.

Mr. V. Warren Low: (1) Aneurysm of the external iliac artery, one month after ligation; (2) aneurysm of the popliteal artery, also one month after ligation; (3) excision of the clavicle for neoplasm; (4) benign growth of tibia; (5) degenerating chondroma in the popliteal region of a boy.

Mr. Leslie Paton: (1) Cases of rodent ulcer treated by carbon dioxide snow; (2) case of scleral trephining for glaucoma.

Mr. W. H. Clayton-Greene: (1) Angioma of the perineum; (2) tumour of the jaw.

Dr. W. J. Gow: Ovarian tumour.

Dr. Graham Little: (1) Alopecia universalis with lichen planus; (2) molluscum contagiosum; (3) favus of the glabrous skin; (4) acne varioliformis; (5) double labial chancre with a rare form of secondary rash—a small follicular syphilide.

Mr. Cecil Graham: A case of pharyngectomy for malignant neoplasm.

Mr. *V. Z.* Cope: Traumatic sensory aphasia, produced by subdural effusion of blood over the angular gyrus and just anterior to it, cured by evacuation of the clot.

Dr. L. Colebrook: Three cases of actinomycosis. The exhibitor said that he had demonstrated the presence of the fungus in sixteen cases in the last few years, twelve of which occurred in the two years.

Dr. William Hill gave an œsophagoscopic demonstration of a woman with malignant stricture of the middle third of the gullet, who had had six applications of radium in the last four years. The treatment had been successful in postponing the fatal termination which seemed inevitable when it was started. Dr. Hill exhibited the apparatus which he used for applying the radium.

Dr. Parry Morgan gave a demonstration of cases and charts illustrating the effect of the pneumothorax treatment of phthisis. A special apparatus which he had devised was shown.

Dr. B. H. Spilsbury exhibited some interesting pathological specimens including a lithopædion probably produced from an extra-uterine gestation, a myxosarcoma of the lower end of the tibia originating from periosteum and the bladder and urethra of a man who died from acute gonorrhœal septicæmia, showing active suppurative inflammation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

The President, T. Percy C. Kirkpatrick, F.R.C.P.I., in the Chair.

Meeting held Friday, January 16th, 1914.

The President's Address, which was illustrated by lantern slides, dealt with the origin of some of the existing Dublin hospitals.

ADMISSIONS TO THE WESTMORLAND LOCK HOSPITAL, DUBLIN, SINCE THE YEAR 1860.

Dr. Pugin Meldon read a paper on this subject, for which see p. 139.

Mr. Henry Moore urged the necessity for the Section of the Academy to lay its views before the Royal Commission at present sitting to enquire into the subject of venereal disease. He referred to the fact that the terms of reference excluded the consideration of the conditions under the Contagious Diseases Act. It was pointed out that a number of bodies had taken on themselves to forward suggestions to the Commissioners, many of which were stated to be of little use in stopping the spread of the disease. The principal source of venereal disease was the prostitutes, and unless something was done to stop the disease amongst them and make them come up for treatment energy would only be wasted. In his opinion every medical body ought to express its opinion very definitely on the subject. Another matter of importance was that general hospitals should be called upon to undertake the treatment of syphilis and gonorrhœa, as otherwise students could not be expected to be acquainted with the diagnosis and treatment of such affections. He expressed the opinion that the General Medical Council ought to be called upon to refuse the certificates of any hospital that did not treat venereal cases.

Dr. Matson said he thought that the incidence of the disease was decreasing. He was struck by the objections which some respectable women who had contracted the disease had to go for treatment to the Lock Hospital. His view was that this hospital should be looked upon as the proper place for treatment of every woman so suffering. He considered that a patient suffering from this condition was just as deserving of relief as one affected with any other illness. He pointed out that in Dublin there was a large number of women known as "Privateers" who spread infection much more than the regular prostitute. He mentioned that the increase of venereal disease in Liverpool was found to be enormous after the repeal of the Contagious Diseases Act.

Dr. Rowlette said that accurate statistics on the subject were most necessary, and if notification could give accurate statistics it would so far be of use, but it seemed to him that as a preventive of the disease notification would be the worst step that could be taken, as it would, he considered, put a barrier in the way of early treatment. If a patient suffering from venereal disease were to be notified he thought the result would be that he would not seek treatment until forced to do so. He considered notification a most dangerous step, and expressed the hope that the profession would be opposed to it. He suggested that if each medical man was asked to make a return of the number of cases treated by him without giving any names some help might be given, although he was alive to the fact that in this way there might be overlapping by the same patient consulting different doctors.

The President said that any return to the Contagious Diseases Act was not only unlikely, and would be unsatisfactory, but was absolutely impossible and outside practical politics at present. He did not think that the notification of infectious diseases had proved the great panacea which the Public Health Authorities would have them believe. He agreed with Dr. Rowlette that any form of notification of venereal disease would tend rather to increase the disease than diminish it. He looked forward to early and accurate diagnosis to diminish the disease. He considered that every medical man should have at his disposal the latest scientific methods for making accurate diagnosis, and this he believed would do more to stamp out the disease than anything else. His experience was that men were not adverse to treatment, but that there was some difficulty in getting them to continue it sufficiently long, but provided an early and accurate diagnosis could be made he thought that much could be done to stamp it out at all events in men. He did not consider there was any great change in the severity of the disease.

Drs. Day, Nesbitt, Crofton and Winter also spoke, and Dr. Meldon replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held February 4th, 1914.

The Vice-President, Dr. Melville Dunlop, in the Chair.

Dr. George Mackay showed a child of fourteen months, illustrating unusual rapidity of absorption of lens matter after needling for congenital cataract. It was important to operate early in order that the child might learn fixation. In this case a glow from the fundus could be obtained on the eighth day.

Dr. Mackay also showed a case after trephining the corneo-sclerotic junction and peripheral iridectomy for glaucoma.

Dr. Chalmers Watson showed specimens of ascaris lumbricoides and ova, and the ova of trichocephalus dispar.

Dr. Edmund Price gave a communication and lantern demonstration on the Röngten Ray and Bismuth Meal method as an aid in the diagnosis of some alimentary diseases.

He insisted on the importance of other methods and said that a special use of Röntgen rays was in confirming results arrived at by other methods. Fallacies might arise from faulty *technique* from failure to take a series of photographs or from neglect of other methods. He cleared out the bowels the day before the observations, gave a meal of bread and milk along with 2½ ounces of oxychloride of bismuth or sulphate

of barium in the morning, made a preliminary screen examination, and then took the first photograph. The next was taken in 3½ hours. Ordinary meals were then allowed. Subsequent photographs were taken at 8, 12 and 24 hours after the test meal. Sometimes later views were required.

It was thus possible to tell the position of the alimentary organs and to gain information about their movements. In stasis it was possible to tell the site of delay and to form an opinion regarding the condition of the wall of the bowel.

The position of the transverse colon always corresponded to that of the stomach. If the stomach was low so was the colon.

Mr. Scot Skirving suggested that the appearance of atrophic intestinal wall might in some cases be due merely to the presence of gas, and asked how adhesions could be distinguished from spasm.

Dr. Gulland agreed with Dr. Price's views. Unless the screen was used at frequent intervals there was a great liability to error.

Mr. Stiles said that the X-rays gave great help to the surgeon. It was not so much an advantage to the surgeon to be told what he was likely to find as to enable him to tell the patient what it was likely that he would have to do.

As a rule, he preferred to excise the piece of colon at fault in intestinal stasis rather than perform ileo-sigmoidostomy.

Professor Russell said he would gladly have listened to a wider exposition of the subject. When differences arose between the clinician and the radiographer they were due to differences in interpretation.

Dr. Byrom Bramwell gave a communication on diffuse scleroderma. He had seen nine cases, all in men. Eight were stonemasons, and one was a coppersmith accustomed to use a cold chisel.

He had obtained much benefit from the use of fibrolysin, but in several cases he had found after the seventh or eighth injection a remarkable rise of temperature.

Dr. Cranston Low said that the condition was rare and that all his cases had been females. He suggested that the rise of temperature seen after fibrolysin was a manifestation of anaphylaxis.

Dr. Fleming said that he had not found much benefit from fibrolysin unless it had been combined with massage.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the twelfth meeting of the Royal Commission on Venereal Diseases, held on January 23rd, evidence was given by Dr. J. Kerr Love, aural surgeon to the Royal Infirmary of Glasgow, aurist to the Glasgow School Board and to the National Bureau for the Deaf.

Dr. Love's evidence dealt largely with the importance of syphilis as a cause of deafness in children. This syphilitic deafness, he said, was essentially a disease due to untreated syphilis amongst the poor. He was of opinion that about 25 per cent. of the cases of congenital deafness were due to syphilis, and that this form of deafness was hardly ever cured; better general health could be obtained for the children by treatment, but the restoration of hearing was rarely possible. The cost of education in the case of a deaf child was at least five times as great as in the case of a normal child, so that even from the financial point of view alone the matter was a very serious one.

Dr. Love illustrated the effect of syphilis on child life by showing a number of family trees of families affected with syphilis: the record of 21 families showed that two-thirds of the children born were born dead, or if alive were blind or deaf or both. He considered that improved treatment of syphilis was urgently demanded, and that this treatment should be placed within the reach of all. He thought that some form of notification of the disease was desirable, but that universal and compulsory notification was not at present feasible.

It might, however, be prudent to attack syphilis by a flank movement and to notify certain conditions which are often due to congenital syphilis, following up the information obtained by treatment of syphilis if the Wassermann reaction or any other test that might be applied indicated its presence.

At the thirteenth meeting Major Harrison, R.A.M.C., Pathologist to the Royal Army Medical Hospital, Rochester Row, gave evidence. He said that the chief cause of the late manifestations of syphilis was inadequate treatment, and that since the treatment of syphilis in the Army had been systematised, malignant syphilis had become almost unknown. Adequate treatment should be commenced at the earliest possible stage after the establishment of the diagnosis and should include prolonged observation clinically and by all laboratory tests until the doctor is satisfied. Major Harrison described the methods of diagnosis in use in the Army, and stated that the diagnosis of syphilis, which in former years was often difficult, had now become as exact as that of almost any other disease. He referred also to the importance of gonorrhœa, and gave an account of the methods adopted at the Rochester Row hospital in connection with this disease. He held the opinion that it was very important that both medical practitioners and the general public should be educated with regard to venereal diseases, and he laid stress on the desirability of obtaining legislation to prevent unqualified persons from treating these diseases. With regard to the question of notification, he advocated a system of confidential notification at the option of the local authority.

In view of the importance of providing facilities for diagnosis in order to secure early treatment, he thought that district and county laboratories should be established under the direction of a central national laboratory, and he submitted a scheme for such a national laboratory service.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Feb. 7th, 1914.

At the Surgical Society, Hr. Kölliker related two cases of

Hemolysis with Paralysis of the Radial Nerve. In the first case, which was shown, there had been a fracture of the left upper arm 10 ctm. below the head of the humerus, and a left-sided fracture of the radius after a fall from a two-storey height on January 6th, 1913. The paralysis of the radial was first ascertained early in April. Operation on April 15th. There was complete paralysis of the nerve and reactions of degeneration. The radial was exposed between the internal brachial and brochio-radialis and followed upwards. The proximal end of the nerve was first found at the sulcus on the median side of the upper arm, and united to a process of bone. The attachments were severed and the nerve extended. The bony exostosis was chipped off with the chisel and the part left smooth. A pedunculated flap of fatty tissue was sutured in between the bone and the nerve. As the part lying between the brachialis internus and the brachio-radialis was changed by cicatricial tissue, the old bed of the nerve was closed by suture, and the nerve placed over the brachio-radial after a bed of fatty tissue had been made for it. The first appearance of recovered motility was noticed in September, five months after the operation and eight after the accident. Early in November it was ascertained that perfect function had returned.

In the second case the left upper arm had been crushed in a railway accident between two iron bars, leaving a furrow of contusion and complete paralysis of the radial nerve. Operation four months after the

accident, followed by immediate restoration of function. The middle third of the radial was embedded in cicatricial tissue. Here also the old nerve bed was obliterated by suture, the nerve being placed in its new position on the muscular tissue after being enveloped in fatty structures, to which, however, a pedicle had been retained.

Hr. Töpfer spoke on the

Treatment of Gonorrhœal, Articular and Serous Affection by Vaccines.

He said he would wish to draw very shortly the attention of the Society to some recent cases of the above-named affection treated by means of vaccines. The treatment consisted of vaccination—*i.e.*, of active immunisation. It was first introduced four years ago by Bruck in Breslau, and was founded on that of tuberculosis by neo-tuberculin. Bruck had brought the vaccine into the market under the name of "Arthigon." It was an emulsion of gonococci prepared by washing the gonococci with saline solution and then killing them. The injections were given every six or eight days, and consisted of 0.1 to 0.6 c.cm., intravenously. The dose was increased each time by 0.1 c.cm. Reaction generally took place, the temperature rising often to 40° C., with considerable disturbance of the general condition. Distinct improvement was noticeable after even the first injection: the stiffened joints could be more easily moved, the tenderness on pressure over the serous cavities gradually gave way. Recovery was assisted and accelerated by keeping the parts affected at rest.

At the Verein für Innere Medizin und Kinderheilkunde, H. Aronson spoke on

Experimental Investigations on Tuberculin and Tuberculosis.

He said there were two separate views as to the action of tuberculin. The first was that the action was direct on the tuberculous organism, that as a primary poison it set up a reaction, against which there was an excess of sensibility. The second view was that the effect was to be attributed to antibodies present in the serum of tuberculous individuals. The speaker had before raised objections to these views, and his objections had been confirmed by more recent inquiries. All methods of determining the presence of antibodies in the serum of the tuberculous had failed. The complement separation did not taken place when, in place of the usual tuberculin, extracts were made use of that were prepared in such a way that they no longer contained fatty constituents. The Höchster tuberculosis serum certainly caused complemental separation with tuberculin, but it did with other bacterial extracts also, and expecially with diphtheria bacilli. Besides, the Höchster serum contained no anticutines, substances that stopped the action of the Pirquet test. Further, the tuberculin oversensibility could not be transferred passively from tuberculous guinea-pigs to healthy ones. The speaker was not able to find tuberculin antibodies in tuberculous guinea-pigs, such as F. Meyer had found in the erythrocytes of tuberculous rabbits. It was also possible to set up the tuberculin reaction with other bacterial extracts; for instance, with a diphtheria bacillus extract prepared by himself. But a positive skin reaction was never obtained with such substances. In any case, on the basis of the facts stated, any view of a specific tuberculin reaction must be abandoned. The speaker then passed on to tuberculosis therapeutics. Normal guinea-pigs could not be immunised. In other ways also extracts of tubercle bacilli, and even killed off bacilli themselves, did not cause immunity. But on the other hand, treatment with living bacilli that were not toxic for the animal being treated did exert immunising influences, and such experiments had now been made by F. Klemperer, Müller and Friedmann. At the same time it was inadvisable to inject living bacilli into the human subject, and it was to be wished, if possible, to produce the immunisation by bacilli that had been killed off.

Hr. Meyer said that as tuberculin did not cause immunisation, it should no longer be employed in treatment.

Hr. Klemperer took his stand on the point that tuberculin did not cause immunisation. He had performed the following interesting experiment:—If cutaneous tubercle was set up in a rabbit by injection of human tubercle bacilli, an injection of tuberculin, immediately after extirpation of such a patch of tuberculous disease, did not cause any reaction. The reaction was set up, however, if living bacilli were injected. The organism therefore contained antibodies against living tubercle bacilli only.

Hr. Barth had made an experiment similar to Klemperer's with a like result.

AUSTRIA.

Vienna, Feb. 7th, 1914.

Relation of Heredity to Climacteric Periodicity in Health and Disease.

At the recent Versammlung Deutscher Naturforscher und Aerzte in Vienna, Dr. Hermann Swoboda presented a new aspect of a very old question in a communication on "The Significance of the Septennial Period in the Problem of Heredity." The fact of the special importance of the septennial stages of human life was recognised of old by the Pythagoreans. It has been observed that the development of the organism moved by steps, either forwards or backwards, at those periods; and these were, accordingly, referred to in the medicine of ancient times, by which they were firmly upheld, as stages in the years of human life. These periodic years have now, however, an even far greater significance than could have been dreamed of by the most daring of the speculators of ancient times in the domain of the properties of numbers; and more especially, as had been proved by Dr. Swoboda's own exhaustive researches, in relation to the question of heredity. The law at which he had arrived could thus be enunciated, in its most widely generalised formula; Every human being originates from ancestors from whom he diverges by steps of seven years in the direction of old age. As everyone's individual being thus passes through a stage of renaissance every seven years, so likewise was celebrated in the same rhythm a resurrection in the progress towards posterity. By means of this law the resemblance between parents and children is most clearly illuminated. A child who wholly inherits the features of the father, and thus approaches the latter in similarity of appearance and disposition was generated at the passing of one of the paternal septennial steps; thus also in case of inheritance of those of the mother. Confirmations of this law are readily obtainable. Many such are afforded by historical cases: the philosophers Fichte and Herbart, who resembled their respective mothers in every feature, were born in her 21st year in each case; the poet Björnson, who resembled his father to a confusing degree, was born in the 35th year of the latter; Manzoni in his own father's 49th year; Siegfried Wagner in Richard's 56th. A splendid example of climacteric heredity is afforded by Bismarck. According to all biographers, two distinct elements were recognisable in the Iron Chancellor, which were respectively derived from his parents. From his boyhood Bismarck possessed a vigorous bodily constitution, and high intellectual endowments derived from his mother, Wilhelmine Mencken, who came of a family of learned jurists and scholars; while a third element, which was supplied in the form of a love of nature and of life on the land and in the forest, as well as of antiquity and old age, was transmitted by Kekule von Stradonitz to the forest family of Boeckel, which formed part of the ancestry of Bismarck's mother. As intellectual ancestor there appears, however, in the most prominent position of all, his maternal grandfather, Anastasius Ludwig Mencken, who was the Geheime Kabinettsraf of Frederick the Great, who was raised to this high position by his great capabilities, and who, according to some historians, was hindered only by his physical delicacy from the accomplishment of still greater achievements. What was wanting in him came to Bismarck from the paternal side, who thus represents a most fortunate and valuable synthesis of the two elements referred to. But

what makes his case so important to the theory of the septennial period in relation to heredity is the following chain of facts: Bismarck was born at the date of a multiple period of several of his ancestral births—63 years after that of Privy Councillor Mencken, 120 years—less a year—after that of the Dragoneroberst, and 91 years after that of Frau Forstmeister Boeckel at Selchow. And what is especially notable is the fact that, of the last fourteen ancestors of Bismarck, the three just mentioned are the only ones who were separated from at date of birth by a corresponding serial interval. It was an auspicious coincidence, from the moment of ancestral union, not a mere fortuitous one. On the ground of the climacteric theory here enunciated we could have foretold who were the ancestors destined to concur in the genetic development of Bismarck; but not so confidently how this concurrence would work out: whether the growing Bismarck would form according to the model of a single one of those ancestors, or in what proportion the contributory elements would be mingled, or which would prove the sustenance of the body and which of the mind, respectively. Here the climacteric theory falls short, at least in this preliminary stage. The septennial stages are, however, those of most pronounced progress in all cases. Accordingly, when anyone inherits a disease or defect, the pathological properties thereof will display expansion at those periods as a constituent element of the whole personality. The child of a tuberculous father begotten in a periodic stage (28th, 35th, etc., year) will very probably prove tuberculous; while those begotten at corresponding dates by a healthy father are the only ones likely to escape when the mother is tuberculous—granting that the pathological factor of the ancestry does not predominate continuously.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

A YEAR'S WORKING OF INSURANCE IN SCOTLAND.

MR. JAMES LEISHMAN, Chairman of the Scottish Commissioners, reviewed the year's work under the Act at a conference held in Glasgow on the last day of January. There are in Scotland 1,470,000, most of these being compulsorily insured, about 1,500 voluntary insurers, and about 36,000 deposit contributors. The Insurance fund amounts to about $3\frac{3}{4}$ millions, and $1\frac{3}{4}$ millions has been paid out—about £1,100,000 for benefits and other administration, and the remainder for medical benefit and its administration. Nearly £2,000,000 has been accumulated for future benefits and reserve. Nearly 27,000 persons connected with societies get money benefit every week, 18-19,000 get medical benefit; altogether, including sanatorium benefit, nearly 50,000 persons got some kind of benefit. As regards the deposit contributor, Mr. Leishman said that the problem must be dealt with by Parliament this year. It was an open secret that no fewer than three societies had offered to take over the whole of the deposit contrubutors, and he did not think this really a courageous offer, for there was a surplus of somewhere about £30,000 on the year's working in the deposit contributors' fund. Among other speeches made at the conference was one by Mr. Appleton, London, secretary of the General Federation of Trade Union Approved Societies, who introduced a discussion on the difficulties of administering medical benefit, contending that many of these difficulties might have been obviated if the medical profession had taken a more liberal view of their responsibilities, and advocating a State medical service. Eventually a resolution was passed to the effect that the medical referees were not generally acting in accordance with their agreements as regards certifying total incapacity, and desiring that the number of patients on the doctors' lists should be restricted. Malingering was also discussed, and it was agreed that it existed to a certain extent. At a dinner attended by members of the Conference, Mr. Leishman, replying to the toast of The Insurance Commissioners, acknowledged the law-abiding spirit of both employer and employed which had done so much to assist in the working of the Act. Relatively, the resisters were so few as not to count. He regretted that National Insurance had got into the political arena, and suggested that there should now be a "Truce of God" in the interest of public health. He thought that now the doctors in Scotland acknowledged that the Act was a good thing, though some were unwilling to recognise that along with the very adequate remuneration there came a measure of responsibility, and the Societies looked to the medical profession as a bulwark against improper claims. The basis of the Act was financial, and if owing to the lack of appreciation of responsibility by the doctors the Societies were compelled to pay funds which they ought not to pay, the movement in favour of a State Medical Service would receive such an impetus as to make it difficult for any one to resist it.

THE CROPPER SCHOLARSHIP FUND.

The demise, in 1898, of the School of Medicine for Women, established in Edinburgh by Dr. Sophia Jex-Blake a few years earlier; has given rise to difficulties in the administration of this fund. Mr. Cropper executed the deed of trust in 1892, and the income of the fund was to be applied in assisting the education of one or more students of the then existing Edinburgh School of Medicine for Women, with a preference for natives of India. The trustees of the fund have now got authority from the Court of Chancery to transfer the investments and cash to the Queen Margaret College School of Medicine for Women in Glasgow, and liberty was granted to apply to the Court of Session in Scotland for the settlement of a scheme for the administration of the fund. The trustees have applied to the Court of Session accordingly; but the present Edinburgh School of Medicine for Women has come forward and asks for a scheme under which the fund and income would be employed in assisting the education of women students in that school, in preference to Queen Margaret College.

SCOTTISH NURSING CONFERENCE AND EXHIBITION.

This Conference and Exhibition, opened in the Exhibition Buildings, New City Road, Glasgow, on the 7th inst. The speakers set down in the programme include Sir Samuel Chisholm, Bart., LL.D., Dr. Carstairs C. Douglas, Miss Haldane, LL.D., Dr. A. K. Chalmers, the Countess of Eglinton, Dr. Leslie Lyall and Dr. Ernest Thomson. Dr. Chalmers is to speak on "The Need for a Midwives Act in Scotland," and Dr. Lyall on "The Tuberculosis Dispensary as a Sphere for Nurses." An interesting and valuable collection of exhibits has been secured. The charm of novelty attaches to the "Nurses' Invention Stall," organised by the *Nursing Times*. Here are shown various devices and inventions thought out by nurses in the course of their professional duties. A valuable historical exhibit, lent by Dr. W. J. Dilling, of Aberdeen, includes an Egyptian section and exhibits relating to Greek and Roman and Early and Middle English medicine, and old pharmacy. It also contains medical and surgical instruments, including eye instruments, and prints and books illustrating the history of medicine, and portraits of eminent medical men of the past.

BELFAST.

BELFAST MEDICAL STUDENTS' ASSOCIATION.

THE annual public meeting of the session was held in the McMordie Hall of Queen's University, on the 26th ult. Dr. T. S. S. Holmes, the newly elected President, in his presidential address gave an interesting *résumé* of the inauguration of the Association and the benefits which it had gained for the medical students of the Belfast School. In the early days of Queen's College, most of their medical students graduated in the old Queen's University, and later in the Royal University. They suffered some disabilities owing to the fact that the examining boards were all composed of Dublin men, the Belfast students not having at that time any representation. The Association took the matter up, and in due time succeeded in getting several examiners from Belfast appointed. Sir John Byers and Sir Wm. Whitla were

the two first appointed, and since then others were added. The Association also approached the authorities of the Belfast Union Infirmary, but did not at that time succeed in getting that vast institution to open its doors to the medical student. In other ways the Association worked in the interests of the medical student, and had taken a conspicuous part in bringing the Medical School to its present prosperous condition. The first rule drawn up by the Association was to promote in every way the interests of the students as regards their professional training. That rule had been kept in view throughout the history of the Association. Dr. Holmes then introduced the lecturer of the evening, Professor Benjamin Moore, F.R.S., an old Queen's student, who dealt at some length with the need for drastic reforms in our present system for supplying medical treatment to the working classes and the poor. Professor Moore is, as is well known, one of the strongest supporters of a State Medical Service. He dealt with infantile mortality, and showed how, in his opinion, a State Medical Service would benefit the children. Under the present system the doctor waited till the children were brought to him in a state of illness. Under the proposed scheme the doctor would look after the children so as to prevent illness. Epidemics would thus be detected in an early stage, and the practitioner would go through the districts in order to find out and isolate cases of infectious disease before serious harm had been done. He believed that things would not be right until a Minister of Health were appointed, whose fundamental duty it would be to look after the health of the community. Dr. Moore pointed out that under such a scheme as he advocated people could still choose their own doctor. He did not think that this was of so much importance as many seemed to imagine, as very often other things than ability to diagnose and cure disease determined most people in their choice of a doctor. He did not want a part time, underpaid, starved and pauperising system as they had in the poor law system all over the country, but an adequately staffed, properly paid, completely organised system raised to the standard of that of our voluntary hospitals.

In the discussion that followed, Sir Otto Jaffé, a member of the Belfast Corporation and a former Lord Mayor, Sir John Byers, Dr. John Campbell, Dr. Gardner Robb, Dr. John Rusk, and Mr. Andrew Fullerton took part.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE NORMYL TREATMENT ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The name of this Association seems to have disappeared from public view. I am told the Association is dead. If this be so, I venture to affirm that its founders and managers are under a deep obligation to the public in general and to the medical profession in particular to furnish particulars of its latter-day history and its demise. I have not at hand the list of governors, but among its foremost supporters I recall the names of Mr. Cecil Chapman, a metropolitan magistrate, his brother, a clergyman of the Church of England, and Mr. Owen Seaman, the Editor of *Punch*, an astute man of the world, whose work includes the constant shooting of folly as it flies.

The Normyl remedy was, we were told, the discovery of a young chemist who hailed from one of the great Dominions. It was described as a secret remedy, one of the ingredients of which defied the attempts of analytical chemistry to identify it.

If a true remedy of this kind for inebriety existed there would not be the least difficulty in scientifically demonstrating its efficacy. It would render its discoverer as great a benefactor to mankind as Jenner, Pasteur, or Lister; and, if, unlike these great men, he demanded a money reward, he might, by maintaining the secrecy of his treatment, amass wealth far beyond the dreams of avarice. From first to last no steps were taken to submit the Normyl remedies to a scientific tribunal, so that if established suffering humanity throughout the world might participate. In every civilised country there are at work institutions and scores of scientific workers who will eagerly examine any new treatment offering the least claim to scientific attention. No steps of the kind were taken, and the Normyl treatment has been virtually ignored by scientific authority in every land. It presented no greater claim to consideration than the bulk of secret remedies to which similar powers are ascribed.

Many persons taking alcohol to excess give it up when the mental or physical pain from which they have been suffering is assuaged, perhaps by suitable moral influence or by medical treatment. These are very different from the cases of moral obliquity of infinite variety discoverable among drunkards and dipsomaniacs, and from the cases in which the nervous system, brain, and spinal cord have suffered alcoholic degeneration.

If any remedy could neutralise the mental and physical causation of even a small class of cases, if it could cure drunkenness arising from half-a-dozen out of the many more distinct causes it would be miraculous. Belief in remedies of this kind is due to illusions and delusions which commonly arise in the minds of men ignorant of science and scientific methods in general, and of medical science in particular. There is not the shadow of a reason to throw doubt upon the good faith of all concerned, including the inventor or discoverer of the remedy; but there seems more than enough of imperative reason on grounds which they will surely recognise why the supporters of the Normyl Association, who at great self-sacrifice promoted it and forced it into public view, should now furnish an account of their stewardship and of its ultimate results.

I am, Sir, yours truly,
MEDICAL TEMPERANCE REFORMER.

WHAT IS THE SPECIFIC FOR SYPHILIS?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is impossible for anyone who has been in any line of practice for upwards of forty years not to have seen closely a great number of cases of syphilis, and not to have had an instructive, if more distant, view perhaps of a still greater number. My retirement from practice synchronised with the introduction of salvarsan, but if I were asked to reply to Dr. McWalter's query which heads this letter, I should, from my own personal knowledge, unhesitatingly reply, mercury. At the same time I must avow that if I were consulted in a case at the present time I should advise the salvarsan treatment, keeping mercury as an adjunct, or in reserve, as the best authorities are now doing. I know nothing of salvarsan save what I have read in medical and lay papers. In the *Times* within the last few days I have seen the report of Professor Ehrlich's reception in Paris. The testimony to its efficacy borne by French physicians is alone enough, it seems to me, to make the use of the new remedy almost imperative.

To revert to my own experience, I can recall very few cases of uncomplicated syphilis which ran a bad course when treatment with mercury was properly carried out for a sufficiently long period. The complications which hindered or prevented the success of this treatment were the existence of some other constitutional taint, such as tuberculosis, or some degeneration such as due to chronic alcoholism and malnutrition, and seen in its worst form in the lower class of common prostitute. In my experience old subjects stood syphilis badly, but given comparative youth and previous good health, I had rarely any hesitation in assuring a patient with tolerable confidence that he would be practically free from serious danger, and able to marry without risk to offspring within some period of not much more than four years after primary infection. My teacher and my consultant in syphilis for many years was Jonathon Hutchinson, and his views in the main became mine. He used to point out that the danger of conveying the malady to wife and offspring after thorough treatment had been

greatly exaggerated by Fournier and other French writers, and I could cite any number of cases supporting this view. My only disagreement with Hutchinson was as to the best method of administering mercury. He gave it by the mouth in the form of grey powder. I was convinced that inunction was far the better way. I found that given through the mouth without opium it excited frequent colic and diarrhœa, whilst if opium were added there often followed constipation and disorders of digestion. Early in my career I accompanied a patient to Aix-la-Chapelle, where inunction was carried out so efficiently in conjunction with the sulphur water treatment. I there learnt the proper methods of rubbing in the ointment. These methods, unfortunately, have never been sufficiently widely taught in this country. I enclose my card, and remain, Sir,

Yours truly,
SENEX.

Eastbourne.
February 6th, 1914.

OBITUARY.

MISS JULIA COCK, M.D.

WE regret to announce the death of Miss Julia Anne Hornblower Cock, M.D.Brux., of Nottingham Place, W., which took place on the 7th inst., at Ockham, Surrey. The deceased, who was well known as the Dean of the London (Royal Free Hospital) School of Medicine for Women, was in her 54th year. Qualifying as L.R.C.P.I. and L.M. in 1882, Miss Cock took the L.R.C.S.Edin. in 1890, and became M.D.Brux., with honours, in the same year. She was one of the Examiners for the Board of Education and of women proposers for Government insurance. She was also Medical Inspector of the North London Collegiate School for Girls and of the Camden School for Girls, and held other appointments, and was formerly in practice at Braintree. Miss Cock made various contributions to medical literature, including the memorandum on "Medical Inspection of Secondary Schools for Girls" in the fifth volume of the Report of the Royal Commission on Secondary Education, 1895, and the article on "Rheumatoid Arthritis" in the *Encyclopædia Medica*, vol. x., 1902.

MEDICAL NEWS IN BRIEF.

The Clinical Congress of Surgeons of North America.

IT is announced that the fifth annual session of the Clinical Congress of Surgeons of North America will be held in London during the week beginning July 27th next, an invitation tendered by a committee of London surgeons through Sir Rickman J. Godlee having been presented and accepted at the session of the Congress held in Chicago in November, 1913.

The first session of the Congress was held at Chicago in 1910, with an attendance of 1,000 surgeons; the second in Philadelphia in 1911, with an attendance of 1,500; the third in New York in 1912, with 2,700; while at the fourth session held in Chicago last November 4,000 surgeons registered.

Headquarters for the Congress will be established at the Cecil and Savoy Hotels.

Sentence on a Forger of Medical Certificates.

ALFRED HENRY LINCOMBE HOLWELL, 29, wheelwright, was charged last week at the Devon Assizes at Exeter with obtaining from Arthur Richard Prothero, Secretary of the Loyal Lord Courtenay Lodge of the Independent Order of Oddfellows, various small sums of money by means of forged medical certificates at Staverton.

Prosecuting counsel said the prisoner was first a member of the voluntary section of the Society, but in June, 1912, he was also admitted a member of the approved society of the Order under the National Insurance Act. On June 23rd he obtained from Dr. Gibson, his panel doctor, a certificate that he was suffering from asthma, and by means of forging a doctor's certificate he afterwards obtained benefits both under the State and voluntary sections of the Society to which he was not entitled. When at work he earned 15s. a week, but when receiving the benefits of the Society he drew 20s. During part of the time he received benefits he was actually in work.

Prisoner, who was said to be a married man with two children, was sentenced to six months' hard labour, and the Commissioner, having passed sentence, said that the prisoner had committed an exceedingly mean offence towards friendly society members, and, considering the vast organisation which was now in existence to prevent persons improperly getting money payable under the national insurance from either the Government authority or the approved societies, it was essential that such offences should be punished in such way as would act as deterrent to other persons who were inclined to take advantage in an improper way of what the State had thought fit to provide.

Missing Radium Found.

THE tube of radium, worth over £1,000, which was missing from the Liverpool Royal Infirmary a few days ago has been found among the sweepings of the floor of the ward in a cart which was about to leave the infirmary. The electroscope was successfully employed in the search.

Ophthalmia Neonatorum.

THE Local Government Board issued an Order last week making ophthalmia neonatorum a notifiable disease. The regulation which will have effect throughout England and Wales, will come into force on April 1st.

Gift to Leigh Infirmary.

MRS. GREENOUGH and her son, Mr. T. Greenough, of Beechwood, have presented to Leigh Infirmary, in memory of the late Alderman Greenough, a block of buildings in which to house a complete installation of X-ray apparatus.

Trinity College, Dublin.

THE following have passed Part I. of the examination for the Diploma in Public Health of Dublin University, January 26th-30th, 1914:—Evelyn M. Franklin, L.R.C.P. and L.R.C.S.Edin., Dorothy K. Milne, M.D.Dub., Peter H. Lemass, M.B.Dub., Geo. E. Palmer, M.R.C.S.Eng., L.R.C.P.Lond., Robert H. C. Lyons, M.B.Dub.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

J. C. R. (Beds.).—An efficient automatic flash-tank, working by syphon action, after the pattern of that by Field, would be of service. It may be regulated by the dribble from a tap to discharge once, twice or several times in the twenty-four hours.

M. B. (Edin.).—Cream does occasionally contain tubercle bacilli. Thus, during the year 1911-12, 33 samples of cream were examined in the pathological laboratory of the Local Government Board; one contained tubercle bacilli, proving pathogenic in guinea-pigs.

STUDENT.—Apply to the Secretary, Royal College of Surgeons, Lincoln's Inn Fields, W.C.

"THICK AS THIEVES IN VALLOMBROSA"

LAST week a gentleman wrote to the Editor of THE MEDICAL PRESS AND CIRCULAR demanding an apology for certain statements contained in an article in our last issue under the heading of "Excelsior." The main point appears to be that the well-known quotation of Milton's phrase "Thick as leaves in Vallombrosa" was parodied by our author into "Thick as thieves in Vallombrosa." Our correspondent, who writes us as a legal gentleman, bears the name of Stefano Masticati. The letter reached us on the 4th of February, and as it purports to come from Vallombrosa itself, someone or other must have done us the honour of telegraphing our views to the legal gentleman in question. We may assure him, without further beating about the bush and without equivocation, that there was not the least intention of casting any slur upon Vallombrosa. In fact, the scribes of Fleet Street have been before us on various occasions with the paraphrase, which, nevertheless, seems for the first time to have been brought under Signor Masticati's notice. If it be of any satisfaction to him we withdraw any implied slight upon his classical town, but at the same time we find it a little hard to swallow his confident assertion that there are no thieves in Vallombrosa. That statement suggests that other statistics, such as those relating to magistrates, police, and so on, might have a good deal of interest to readers of a scientific journal. Will the Signor kindly oblige?

DR. SHEPHERD BOYD (Harrogate).—The answer to your question as to the admission of irregular practitioners under the Insurance Act will be found elsewhere in our editorial columns in the paragraph headed "Unqualified Practice under the Insurance Act."

MR. R. BROWN (Norfolk).—There is no doubt that the use of bismuth paste may sometimes give rise to toxic symptoms, the most alarming of which is methhæmoglobinuria. As soon as any intolerance is manifest, the fistulous passages should be irrigated with warm olive oil, as recommended by Zollinger.

M.R.C.S.ENG.—The course which our correspondent proposes to adopt would be quite in accord with ethical rule.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 11TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY: SUB-SECTION OF PROCTOLOGY) (1 Wimpole Street, W.).—5 p.m.: Paper: Mr. Hamilton Drummond: An Anatomical Study of the Vessels of the Pelvic Colon and Rectum, with Special Reference to the Operation for Abdomino-perineal Excision. Cases and Specimens by Mr. Percy Furnivall, Mr. Ivor Back, Mr. C. Gordon Watson, Mr. Sampson Handley.

THURSDAY, FEBRUARY 12TH.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—4 p.m.: Dr. M. Dockrell: Fungous Diseases of the Skin—I., Tinea Circinata; II., Tinea Imbricata; III., Tinea Versicolor; IV., Erythrasma; V., Actinomycosis; VI., Madura Foot.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Discussion on Oral Sepsis in its Medical and Surgical Aspects (opened by Dr. W. Hunter, Mr. Dolamore, and Dr. Charles Buttar).

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Board Room of the Great Northern Central Hospital, Holloway Road, N.).—8.30 p.m.: Clinical Evening.

FRIDAY, FEBRUARY 13TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m.: Cases in which Splenectomy has been Performed or is Contemplated for Disease. Cases will be shown by Dr. T. R. Whipham, Dr. James Collier and Mr. Crisp English, Sir Bertrand Dawson, K.C.V.O., Mr. Percy Sargent, Dr. Herbert French and Mr. Philip Turner, Mr. E. W. Everett (Norwich), Dr. W. Essex Wynter and Sir John Bland-Sutton, Fleet-Surgeon P. W. Bassett-Smith, C.B., and Dr. Thursfield.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lecture:—Prof. B. Whitehouse: The Pathology and Causation of Idiopathic Uterine Hæmorrhage.

MONDAY, FEBRUARY 16TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Adjourned Discussion on The Use of Salvarsan in Ophthalmic Practice, to be re-opened by Lt.-Col. R. H. Elliott, I.M.S.

CHELSEA CLINICAL SOCIETY (St. George's Hospital).—8.30 p.m.: Paper: Dr. Maurice Wright: The Psychology of Freud and Its Relation to the Psychoneuroses. A discussion will follow.

TUESDAY, FEBRUARY 17TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THERAPEUTICS AND PHARMACOLOGY) (1 Wimpole Street, W.).—4.30 p.m.: Laboratory Meeting at the Pharmacological Laboratory, University College (Prof. Cushny). Members desirous of giving demonstrations are requested to communicate with Prof Cushny, or one of the Hon. Secretaries. 5 p.m.: General Meeting of Fellows: Ballot for Candidates for Fellowship.

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Mr. Rupert Farrant: The Pathological Changes of the Thyroid in Disease. Dr. F. H. Thiele: Paths of Spread in Bacterial Infection. Mr. A. C. Morson: The Changes which Occur in Malignant Tumours on Exposure to the Gamma Rays of Radium.

Appointments.

THE Home Secretary has appointed Mr. Arthur H. Norris, M.R.C.S., L.R.C.P., to be Medical Inspector of Reformatory and Industrial Schools, as from April 1st, 1914.

ARMSTRONG, W. H. STIRLING, M.B., Ch.B.Glasg., Visiting Superintendent of Renfrew and Clydebank Joint Hospital for Infectious Diseases.

FIRTH, DOUGLAS, M.D. Cantab., M.R.C.P.Lond., Assistant Physician to the Royal Free Hospital.

MEREDITH, R.W.H., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Wellington District of the County of Somerset.

SHIELD, HUBERT, M.B., B.C.Durh., Assistant Medical Officer to the Gateshead Borough Asylum.

WILLIAMSON, ALFRED J., M.D.Aberd., D.P.H.Cantab, Tuberculosis Official for the County of Essex under the London County Council.

Vacancies.

The Hospital for Sick Children, Great Ormond Street, W.C.—House Physician. Salary £30 for six months, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.)

The Hospital for Sick Children, Great Ormond Street, W.C.—House Surgeon. Salary £30 for six months, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.)

The Hospital for Sick Children, Great Ormond Street, W.C.—Surgeon Dentist. Applications to the Secretary. (See advt.)

County Asylum, Whittingham, Preston, Lancs.—Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Middlesex Hospital, W.—Director of the Institute of Pathology. Salary £800 per annum. Applications to F. Clare Melhado, Secretary-Superintendent.

Derby County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer, Male. Salary £200 per annum, with board, lodging and washing. Applications to the Medical Superintendent.

Warwick County Asylum, Hatton, near Warwick.—Second Assistant Medical Officer. Salary £225 per annum, with board, lodging, and laundry. Applications to Dr. Miller, Medical Superintendent.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—High Wycombe (Bucks), Lynton (Devon).

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Arnesby (Leicester), Ballyward (Down), Midleton (Cork), New Ross (Wexford).

Births.

AIKEN.—On January 25th, at Drumadravey, Irvinestown, the wife of Acheson Aiken, L.R.C.P.I. and S.I., of a daughter.

IREDELL.—On February 7th, at 7 Cumberland Terrace, Regent's Park, the wife of Dr. C. E. Iredell, of a daughter.

Marriages.

PURDON—BOSTOCK.—On February 4th, at Holy Trinity Church, Windsor, Richard H. F. Purdon, of Vancouver, B.C., youngest son of Richard Purdon, M.D., Belfast, to Mary Barbara, only daughter of the late G. Hastings Bostock, 2 Dorset Road, Windsor.

SHINNIE—LEWIS.—On February 2nd, at St. James' Church, Pokesdown, Bournemouth, Andrew J. Shinnie, M.D., Wimbledon, son of the late James E. Shinnie, Aberdeen, to Oliver Victoire, second daughter of the late Arthur Whalley Lewis, Southampton, and of Mrs. F. J. Symons, Bournemouth.

Deaths.

COCK.—On February 7th, at Upton Farm, Ockham, Surrey, Julia Anne Hornblower Cock, M.D., Dean of the London (Royal Free Hospital) School of Medicine for Women, in her 54th year.

ELLIS.—On February 5th, at Walton, Liverpool, Henry Brook Ellis, L.R.C.P. and S.Edin., L.F.P.S.Glasg., aged 70.

MOORE.—On February 8th, 1914, at Priory House, Leamington Spa, John Murray Moore, M.D., aged 70 years.

TURNER.—On January 31st, in a nursing home in Manchester, Robert Ellsworth Turner, L.R.C.P. and S.Edin., L.F.P.S.Glasg., late of Howick, Natal.

WISE.—On February 7th, at 9, Ravenbourne Gardens, West Ealing, William Clunie Wise, M.D., D.P.H., Barrister-at-Law, aged 76.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, FEBRUARY 18, 1914. No. 7.

NOTES AND COMMENTS.

The Future of the Poor Law.

THE question of Poor Law Reform is one of considerable importance to the medical profession. The medical service of that branch of administration covers a wide ground, and its proper ordering is of vital importance to the public health. That the medical side of the Local Government Board is open to considerable improvement is generally admitted, and it was hoped when Mr. John Burns took over the reins of administration in that Department that wise and salutary reforms would speedily follow. Years have come and gone, and at length the Government have translated Mr. Burns to another portfolio in the shape of the Presidency of the Board of Trade, but, truth to say, the Poor Law service generally, and its medical side in particular, still lack the waters of Tantalus. A host of matters still press for solution by a masterly politician. The salaries of medical officers are in the majority of cases miserably inadequate and their tenure of office insecure. There is no proper system that renders an adequate supply of medical and surgical requisites compulsory, although such provision, together with skilled and ample nursing, constitutes the alpha and omega of success in that direction; nor have we seen that enforcement of central authority without which the whole system of Local Government Board control of the service must remain more or less a farce. From time to time workhouse hospital scandals have come to light with distressing monotony, but the subsequent official inquiries fail to ascertain if the inspectors have previously drawn attention to irregularities in the institution concerned, and, if so, to insist upon their reports being withdrawn from their dusty pigeon-holes in Whitehall.

The Unvaccinated and Other Matters.

A CHORUS of praise for Mr. Burns' achievements as an administrator has gone up in the party newspapers. As the official head of a complex Department he has, no doubt, seen that the machinery works with increased economy and efficiency, but the machinery itself is very much the same as when he took office. Under his sway the number of unvaccinated persons in the United Kingdom has greatly multiplied. The seriousness of that statement will probably be one day realised when the nation is face to face with a widespread small-pox epidemic. Compared with the far-reaching social reforms that have been brought about by his colleagues in the Government, Mr. Burns' achievements as a creative politician are trifling and superficial. He has attempted to accomplish by means of Departmental orders that which would be possible only to strong constructive legislation. Whatever view may be taken politically as to such measures of social reform as Old Age Pensions and the National Insurance Act, it will be generally conceded that they must conduce to the advancement of public health. Mr. John Burns, by a well-considered Poor Law Reform measure, might, beyond a doubt, have greatly strengthened the movement which has the attainment of the highest possible standard of national health as its ideal. As to Mr. John Burns' integrity and sincerity, there can be no more doubt than as to his great natural abilities. It is to be hoped that he will find the duties of the Board of Trade more suited to his particular genius than those of the post he has vacated. The new President of the Local Government Board, Mr. Herbert Samuel, brings with him a great reputation as an administrator. It remains to be seen if he will be able to reduce the affairs of the Poor Law Medical service to the level of a humane and businesslike branch of Government activity.

Mr. Masterman and the Back Door to Quackery.

THE translation of Mr. Masterman to the Chancellorship of the Duchy of Lancaster is another Governmental change of interest to the medical profession. The point, of course, is that in his new position he will retain the management of the National Insurance Act. Mr. Masterman has, on the whole, displayed a reasonable amount of tact and forbearance in his handling of the various thorny problems that have arisen under his administration of a much-vexed measure. There is one matter, however, in which he has harkened to the voice of the tempter—namely, in conceding the right to sign certificates under the Act to herbalists and other medically unqualified persons. His reading of the Act was that the decision as to the acceptance of such irregular certificates rested with the local Commissioners. It is to be hoped most sincerely that Mr. Masterman will take a firm attitude with regard to this point, or the dispute with the medical profession may readily begin all over again. It seems unthinkable that any Government should deliberately set itself to stultify the whole trend of the Medical Acts by admitting herbalists and quacks of all kinds by a back-door passage in the Insurance Act. If the State recognises certificates from herbalists for medical benefits under the Act, it must logically accept their certificates for other purposes; and, if herbalists' certificates are to be legalised, so must those of cancer-curers, and the shoals of ignorant charlatans who profess to cure deafness, blindness, epilepsy, locomotor ataxy, kidney disease, and every other ill, curable or incurable, that flesh is heir to.

Municipalisation of Hospitals.

THE robust citizenship of the North of England is being somewhat exercised over the important matter of the municipalisation of hospitals. A spirited correspondence on the subject has been going on for some time past in the columns of the *Yorkshire Observer*. It seems not unlikely that an additional stimulus has been given to the discussion by the recent unfortunate occurrences at the York County Hospital, the executive of which appears to resent and to resist public criticism in a high-handed manner worthy of the traditions of a century ago, but altogether out of touch with modern tendencies. However that may be, a capital suggestion has been made by Mr. Rennie Foster in the above-mentioned journal. With a view of testing public opinion, he suggests that gentlemen who are interested in the subject should take steps for the Lord Mayor to be petitioned to convene a Commission upon which the Health Committee, the voluntary hospitals, the Insurance Commissioners, the school clinics, the Guardians, and other bodies interested in the physical well-being of the city should be appropriately represented, and that the Commission should report whether they considered the time was now ripe for the co-ordination of the various agencies dealing with accidents and disease, and with the furtherance of public health, and, if so, that they should prepare a scheme for co-ordination on an efficient basis for the consideration of the City Council. The idea is an excellent one. Whatever the future may have in store, it seems tolerably certain that voluntary enterprise will never lack a field for useful service.

Herbalists and Death Certificates.

THE unsatisfactory state of the law with regard to the acceptance by registrars of death certificates given by herbalists is illustrated by an inquest which was held the other day at West Ham, and reported in the *Stratford Express* of February 7th. It appears that a mother took her baby, which she thought was "going to have a fit," to a gentleman who she thought was a doctor, but who described himself as a "certificated medical herbalist by examination." She was told that her child was suffering from pneumonia, and was given cotton-wool, oils and medicine. Three days later the baby died, and a certificate was given to the mother by the herbalist stating that death was due to pneumonia, exhaustion and heart failure, and a fee of two shillings was paid him. The certificate not being accepted by the registrar, a *post-mortem* examination was made by a qualified medical man at the direction of the coroner, with the result that death was found to be due to meningitis, the lungs being healthy. In reply to the coroner, the herbalist admitted that if he had known that the child was suffering from meningitis he would have given different "treatment," but that "the child did not present any signs of meningitis to him." He further stated that he had had forty years' experience and that he passed his "examination" thirteen years ago. By refusing to accept his certificate he said that the authorities thought "to intimidate him from trying to save human life." The coroner remarked that the herbalist was not responsible unless he held himself out to be a doctor. Fortunately for himself he made no such pretence, hence the verdict was one of natural causes. If the National Insurance Act permits unqualified persons to treat insured patients these tragic occurrences will inevitably become more common.

LEADING ARTICLES.

THE DWINDLING FAMILY IN SCOTLAND.

THE steady decrease in the national birth-rate of the United Kingdom has for some time past presented matter for serious consideration. In spite of the increasing wealth and prosperity of the community, the number of births continues to diminish year by year. Anything that is likely to help to a better understanding of this complex social problem, therefore, deserves our earnest attention. The most recent contribution of importance to the literature of the subject comes from Dr. Crawford Dunlop, who is superintendent of the Statistical Department of the Registrar-General for Scotland. Towards the end of January last he communicated to the Royal Statistical Society the results of a minute study of the returns for Scotland from the standpoint of the dwindling family. In his paper Dr. Dunlop stated that his investigation fully corroborated the broad conclusion come to by Drs. Newsholme and Stevenson, some years ago, that there is an undoubted decrease in the average of the family, and that this is "not entirely associated with delay of marriage." His researches tended to show that the influence of such delay on the size of the family was enormously greater when it occurred in the case of the woman than of the man. Working out the data at his disposal by means of formulæ, Dr. Dunlop arrived at the result that a delay of three years on the part of a wife (at age 20 to 25) reduces the average size of the family approximately by one child, but that it "requires a delay of something like forty years on the part of the husband to effect the same reduction." The practical bearing this interesting observation is at once apparent. Dr. Dunlop quoted figures which showed, among other things, that, comparing the average Scottish family with the corresponding figures for similar marriages twenty years earlier, the decrease in size of family was universal; and that for all ages under 36, age 32 excepted, that decrease amounted to more than one child per marriage. Thus, while in 1866 the wife who had married at 20 had, on an average, a family of eight or nine children, in 1886 she was the mother of seven or eight children; and so on. The table appended bears out Dr. Dunlop's contention that it is not with delay of marriage alone that the dwindling Scottish family is to be associated—the marriages at a later age to-day show a relatively diminished number of children compared with the similar marriages twenty years before:—

Age of wife at marriage.	Date.	Average family.	Date.	Average family.
27	1873	5.85 ...	1893	1.67
28	1874	5.08 ...	1894	1.11
29	1875	4.91 ...	1895	1.38
30	1876	4.57 ...	1896	1.38
31	1877	4.35 ...	1897	1.48
32	1878	3.48 ...	1898	0.82
33	1879	3.76 ...	1899	1. 6
34	1880	3.44 ...	1900	1.25
35	1881	2.80 ...	1901	1.11
36	1882	2.40 ...	1902	0.72

This highly important table should be of interest to politicians as well as to men of science and statisticians. Dr. Dunlop also dealt with the question of the relations between the working mother and the home, so far as the census figures illustrate them. Married women with remunerative occupation are not numerous in Scotland; the returns showed only 31,465. To compare the influence of other than domestic work on infant mortality, marriages which had been only a limited time in existence had to be taken, as the schedule showed only the number of children who had died in the case of marriages, and where the marriage had lasted forty, fifty or sixty years, the deaths entered might obviously not indicate decease during childhood. The cases investigated were those where the duration of the marriage was less than fifteen years. There were 5,458 such, and, for the purposes of comparison, a case similar in point of age of wife and duration of marriage, but in which the wife was not occupied, was selected for each case of a working mother. It was found that the total number of children born to the 5,458 wives who were not working was 13,970, and to the 5,458 wives who were, 12,881. The disparity in the rate of mortality was shocking. Of the children of the mothers not employed 2,062, or 14.8, were reported in the census to be dead; of the children of the working mothers 3,091, or 24.0 per cent. That is to say, mortality among the children of the working married women was 62 per cent. higher than in the case of the mothers who were unemployed. The degree of seriousness of the declining birth-rate is largely relative to the existing infantile mortality. From that standpoint, Dr. Dunlop's last-quoted figures, however deplorable the position they reveal, nevertheless indicate a direction in which there is room for considerable improvement.

CURRENT TOPICS.

The Institutional Treatment of Syphilis.

The generous offer, recently made by the Grocers' Company, to present a ward to the London Hospital providing accommodation for the treatment of syphilis is yet one more instance of the public-spirited and beneficent enterprise of this corporation. It must be admitted that little or nothing has been done in the past to provide in-patient treatment for cases of active syphilis in the large hospitals of the metropolis. Indeed, some of them, by their constitution, have actually refused admission to syphilitics on grounds of morality and contagion. With the spread of knowledge, and in the interests of the public health, many of these institutions will now have to revise their by-laws, and to provide accommodation in the wards for the treatment of syphilis just as much as for tuberculosis. If we may venture to foreshadow one, at least, of the recommendations of the Royal Commission on Venereal Diseases now sitting, it is more than likely that all the general hospitals of this country will be required in the near future to organise and equip special departments for the treatment of venereal disease where none already exist. It is well known that on the Continent syphilis and skin diseases are treated together, and most, if not all, of the foreign journals dealing with dermatology also include syphilis in their titles. Cases of syphilis certainly present themselves in greater numbers in skin than in any other clinics, therefore it seems reasonable to combine venereal and dermatological departments. Now that the treatment of syphilis by salvarsan and neo-salvarsan has come to stay, it is only right to do the best thing for the syphilitic by providing him with in-patient accommodation while intravenous injections are being carried out. It is true that such injections are frequently given in specialists' consulting-rooms and in hospital out-patient departments, but some slight risk undoubtedly attaches to the practice. It is to be hoped that the good example of the London Hospital in helping to diminish this risk may speedily be followed by other institutions.

Oliver Goldsmith, M.B.

At a recent meeting of the Historical Section of the Royal Society of Medicine, Sir Ernest Clarke made a communication concerning Oliver Goldsmith which cannot fail to be of interest to all medical men who care for literature, and particularly to graduates of Dublin and Oxford. Most lives of Goldsmith state that he pursued his medical studies at Edinburgh, and obtained a degree in medicine at some foreign university, probably Padua. Some writers, indeed, have presumed to be sceptical as to his having received any degree in medicine. Sir Ernest Clarke has discovered, however, from various family letters, that Goldsmith began the study of anatomy in Dublin prior to his journey to Edinburgh. That at some time or other, probably between 1756 and 1761, he proceeded to the degree of M.B. in Dublin is proved by an entry in *Jackson's Oxford Journal*, of February 18th, 1769. This runs: "Yesterday, Oliver Goldsmith, Esq., Bachelor of Physick in the University of Dublin, author of 'The Traveller,' a poem; of 'The Present State of Polite Learning in Europe,' and of several other learned and ingenious Performances, was admitted in Congregation to the same Degree in this University." It is unfortunate that the learned bodies of Dublin and Oxford thought so little at the time of the importance of their academic records, that in neither case in there an official record of the admission to a degree in medicine of one of the most illustrious men who ever practised our profession.

The Arnott Memorial Medal.

Although it is true, as Emerson has said, that "the reward of a thing well done is to have done it," yet it is a pleasant thing to receive some tangible recognition for some service rendered or deed accomplished. Especially is this the case when the tribute is paid by one's professional colleagues who, perhaps, are the best able to estimate the real worth of what is thought to be an achievement in medical science. The international character of the Nobel Prize is well known, and also the high standing of the recipients thereof, but there must be many other practitioners who, if not deserving such an exalted position, are, nevertheless, worthy to be honoured in some practical manner by their compeers. The Arnott Memorial Medal, granted by the Irish Medical Schools' and Graduates' Association, is designed for the recognition of heroism or distinction among members of the medical profession holding Irish qualifications. We have received the regulations

governing the award of this medal, and we are requested to draw attention to the fact that particulars of any kind of heroism, or distinguished service, should be reported from time to time to the Honorary Secretary of the Irish Medical Schools' and Graduates' Association at 7, Springfield Avenue, Harrogate. The award is made by the Council of the Association in or about the month of February in every year, after consideration of the qualifications of the person or persons duly nominated and recommended by a Committee, known as the "Arnott Memorial Medal Committee," formed from the Association. We are glad to give publicity to this announcement, as there must be many an Irish graduate and diplomate worthy of being nominated as a recipient for this honour.

Sickness Benefit in Ireland.

SEVERAL letters have appeared in the Irish daily papers in the past few days pointing out the hardship under which insured persons in Ireland suffer when attempting to obtain the sickness benefit to which they are entitled. It is well known that in the case of certain societies, medical officials are retained—and paid out of public funds—for the purpose of examining all claimants for sickness benefit. Medical certificates from the claimant's own medical attendant are ostentatiously treated with contempt. The medical officials of these societies appear to regard it as their primary duty to refuse benefit in as many cases as possible. They are not, of course, at best in a position to form an opinion of much value, as they know nothing of the history of the illness or of the patient's constitution. Apart from this, however, there seem to be many instances of culpable carelessness. Patients suffering from heart disease with extensive dropsy, from tuberculous disease of the lung with extensive cavitation, from subacute rheumatism with inflamed and crippled joints, are ordered off benefit without any physical examination other than a glance in the face and a look at the tongue. We must not be taken as suggesting that all, or even most of, the approved societies are acting in this cruel and fraudulent way, but that such things should occur at all is a scandal of the first magnitude.

"Eye" in Sport.

THE difference between the trained and the untrained sense-organ is seldom, perhaps, so well seen as in the case of the eye. The sense of touch may be educated to a very fine degree for purposes of medical diagnosis, but that of sight or perception can be cultivated to such a high extent that those who have not the same acuity of vision are filled with envy and amazement at the visual feats of hunters, sailors, astronomers, and other specialised observers. It is the knowledge of what to look for and the ability to "spot" it when present that constitutes what is known in sporting circles as "eye," an interesting paper upon which was recently contributed to the Guy's Hospital Physiological Society (*a*). This somewhat complicated special sense requires a cerebral co-ordination of no ordinary character, which can only be acquired by training and experience. Our estimations of speed and distance are useful in the affairs of everyday life, but they are doubly necessary in the case of many sports and amusements involving accuracy of aim and precision in attack. A certain amount of eye is as needful in dodging the traffic when crossing a busy thoroughfare as it is requisite in delivering a smart stroke at billiards. In such sports as golf, rifle shooting and tennis, accurate judgment has to be combined with rapid manual dexterity. The secret of success lies in perfect nervous and muscular co-ordination, which depends upon the possession of normal sense-organs, an active and capable brain to interpret and co-ordinate the sensory stimuli, and an efficient muscular system to carry out the desired action in a rapid and precise manner.

(*a*) *Guy's Hospital Gazette*, January 17th, 1914.

"Hardening" Children.

A newspaper correspondence has been taking place recently with regard to the practice of the so-called "hardening" of children by sending them out in all weathers with bare legs. However praiseworthy the idea may be in a warm climate, it is wholly inconsistent in a country that possesses such fluctuating temperatures as our own. Every medical man knows that, anatomically, the knee-joint is the weakest in the body, and therefore it requires to be kept warmly clad and protected, as far as possible, from the effects of sudden changes of temperature. Neglect to do so may pave the way for tuberculous infection, with its consequent crippling of the joint. Upholders of Spartan practices are fond of quoting the example of Scottish parents, the bare knees of whose offspring bid defiance to cold and injury, forgetful of the fact that the conditions of life are slightly different north of the Border. Teachers of hygiene, health visitors, and others might well inculcate greater care in the clothing of the extremities of children, whereby much needless suffering might be prevented. The true principle on which the clothing of children should be based is that they should be as lightly clad all over as is compatible with warmth, having regard to the state of the thermometer, and that their clothing should be distributed as evenly as possible over their whole bodies.

The Periosteum and Bone Grafting.

Is contact with living bone necessary for the life of grafts, and will transplanted periosteum produce new bone? It has usually been supposed that, in addition to rigid asepsis, contact with living bone is absolutely essential for the subsequent life of a bone graft. Furthermore, it has been considered by some eminent surgical authorities that the periosteum need not be present provided that this osseous contact be secured. Experiments have been recently undertaken by Dr. Clarence A. McWilliams, of New York (*a*) in the hope of answering the above questions definitely. As a result of numerous experimental bone-grafting operations in animals, it was found that living bone grafts have sufficient life inherent in themselves to be capable of permanent growth, even when transplanted into the soft parts. No less than 48 per cent. of the bone grafts without periosteum were successful, whether contact with living bone was made or not. This seems to show that there may be some other factor present making for the life of the grafts than the periosteum or contact with living bone, and Dr. McWilliams holds that this is a sufficient blood supply. This latter is surely obtained when the periosteum is on the grafts, since practically 100 per cent. of such grafts are successful, whether they be in contact with living bone or not or whether they be grafted into the soft parts alone. The practical outcome of the experiments is to confirm the old belief in the value of the periosteum, which should be preserved attached to the grafts as far as possible. Even the periosteum may

(*a*) *Journ. Amer. Med. Assoc.*, January 31st, 1914.

form new bone when transplanted into the soft parts in a certain proportion of cases.

Hereditary Practice.

We hear a great deal about the cult of eugenics and the importance of supplying suitable ancestors for the nation's offspring. No one seems to have troubled himself as to where we are to find these desirable progenitors. Take an ordinary man and woman, sound themselves, and with a sufficient sense of what is fashionable to wish to detect any latent hereditary taints. What are they to do? The man goes to his father and asks to be told all about his family. Very few fathers of grown-up sons could tell with any accuracy the physical or mental history of their parents. We can see this clearly if we look at a few life insurance proposals. They are full of vague or unknown causes of death. The same father, in most cases, will hesitate to tell his son that he has suffered from venereal disease or any mental aberration. The woman will get less facts, and these will be more distorted, and, on the whole, the supply of the desirable ancestors is very limited. We shall have to establish a register with an organisation like an elaborated census, and after two or three generations we shall all of us have ancestors. Probably by that time eugenics will be no more. Spartan exposure or the brutalities of Nietzsche are more direct methods of getting the sort of human beings we want if we know what they are. So far all our ameliorist schemes are means to an end, and that end has never been defined. If we must distort posterity, at any rate we should know what we are out for.

The Surgeon's Clothes.

The *Interstate Medical Journal* tells us of an inspiring suggestion made by Dr. Guy Shearman Peterkin at the Clinical Congress of Surgeons held at Chicago. The suggestion is that surgeons, when operating, should dress in accordance with their mood. The idea is not new in other spheres of human activity. Several actresses have made a practice of changing their frocks and their minds simultaneously. But the operating theatre's sartorial displays have heretofore been confined to a monotonous candidity. But Dr. Peterkin says "there should be perfect harmony between a surgeon's clothing and the mood he happens to be in." A polychrome wardrobe will be an inevitable addition to our hospitals. Our contemporary suggests that there will be difficulties in the literal adoption of the scheme. It pictures the cocksure surgeon, blithely clad in pink and white, opening an obvious abdomen and finding that it had not adhered to his diagnosis. As his chagrin deepens so must the quickly-substituted hue of his clothes, and suits of sabler shade must be at hand. Such a hiatus might not matter in a leisurely laparotomy, but what of hæmorrhage? A restive scalpel, a nick in a big vessel, and the dexterity of Fregoli becomes imperative. An angry scarlet at the mishap, followed by a craven grey lest the patient die then and there must be at hand for momentary donning. And so on and so forth. Clothes are daily more important. They are the only part of a man's appearance for which he can be held wholly responsible. Modes for men have been up to now somewhat neglected, and we are glad to see that Chicago, at any rate, can find time to discuss a technical question of such import to our profession.

Mr. W. J. Tatem, a Cardiff shipowner, has contributed 1,000 guineas to endow a cot as a memorial of his mother at Hamadryad Seamen's Hospital, Cardiff.

PERSONAL.

Dr. F. W. Mott, F.R.S., has been elected a Foreign Corresponding Member of the Neurological Society of Paris.

Dr. J. Ramsay, M.D., has been appointed Assistant Physician to the Blackburn and East Lancashire Infirmary.

Mr. Cecil A. Joll, M.S.Lond., F.R.C.S.Eng., has been appointed Hon. Assistant Surgeon to the Royal Free Hospital, London.

Dr. Kenneth D. Wilkinson, M.D., Ch.B.Birm., has been appointed Pathologist to the Birmingham and Midland Free Hospital for Sick Children.

Dr. Warrington Yorke, M.D., has been appointed to the recently established Walter Myers Chair of Parasitology in the University of Liverpool.

Sir Frederick Eve, F.R.C.S., has been appointed Bradshaw Lecturer at the Royal College of Surgeons of England for the ensuing collegiate year.

Dr. William Permewan, M.D.Lond., F.R.C.S., D.P.H.Cantab., has been appointed to the Lectureship in Laryngology in the University of Liverpool.

Dr. Josiah William Walker, M.D., L.R.C.S., of 206, Peckham Rye, S.E., Resident Medical Officer at the Greenwich Union, left estate of the value of £18,297.

Dr. V. A. Oppel, Professor of Surgical Pathology at the Imperial Academy of Military Medicine, St. Petersburg, has been admitted an Honorary F.R.C.S. of England.

Dr. T. P. C. Kirkpatrick has been elected a Governor of the Rotunda Hospital, Dublin, in recognition of his eminent service in writing the history of the Hospital.

Mr. John Thomas Hartill, M.R.C.S., L.R.C.P., of Manor House, Lillenhall, for many years Medical Officer of Health for the town, left estate of the gross value of £14,052, of which £6,651 is net personalty.

Sir Ronald Ross, K.C.B., F.R.S., will deliver the first of a series of Research Lectures at the Institute of Hygiene, Devonshire Street, W., on Monday, February 23rd, at 5 p.m., on "The Prevention of Mosquito-borne Disease."

Mr. George Jackson, F.R.C.S.Eng., L.R.C.P. Lond, L.S.A., J.P., who has held the post of Honorary Surgeon to the Devon and Cornwall Ear and Throat Hospital, Plymouth, since its foundation in 1887, has been appointed Honorary Consulting Surgeon thereto.

Miss Aldrich Blake, M.D., M.S., Senior Surgeon to the New Hospital for Women, has been appointed Acting Dean of the London School of Medicine for Women in succession to the late Dr. Julia Cock. It is not expected that a permanent appointment will be made to the vacancy for about a month.

Dr. J. Spottiswoode Cameron, M.D., B.Sc., Medical Officer of Health for Leeds, will open a discussion on "House Flies" at a sessional meeting of the Royal Sanitary Institute, to be held in the Council Chamber, Town Hall, Leeds, on Friday and Saturday, February 27th and 28th, at 7.30 p.m.

CLINICAL LECTURE

ON

THE AFTER TREATMENT OF SURGICAL CASES.

By J. M. G. SWAINSON, F.R.C.S.,

Assistant Surgeon to the Westminster Hospital, Surgeon to the Bolingbroke Hospital.

GENTLEMEN,—I propose in this lecture to consider the subject of after treatment of surgical cases. Surgeons vary in their *technique* and many different ways are successful. Our science is progressive and our practice at its best is a happy compromise between empiricism or the knowledge derived from experience, and the newest or more academic science which may be said to be in a state of unstable equilibrium, as it constantly changes. I shall first consider generally certain questions which naturally arise in the treatment of all cases. Then I shall deal with certain complications which may occur, and lastly I shall briefly refer to the after treatment of some surgical operations and affections commonly met with. Firstly as to general questions. It is well to consider the hygienic surroundings of the patient. Fresh air and sunlight are good for a patient and will be provided when possible. A clean room sparsely furnished and the services of a good trained nurse will conduce to the comfort and well-being of the patient. When the patient leaves the operating room, he will be warmly clad and put to bed quickly in a warm bed. Our object is that the narcosis may pass into a quiet sleep, and that there may be little or no vomiting or pain. The question of what position the patient is to be placed in will occupy our attention. When coming round from the anæsthetic, the lateral position or the dorsal position with the head turned to one side will be most convenient for clearing the throat of the patient and attending to the vomiting. If shock is present, the foot of the bed may be raised on blocks. Later, the dorsal position is convenient for many cases, but it is by no means always necessary to rigidly adhere to it. The principle that should guide us is that the patient should be placed in the position of greatest ease provided that it is not harmful, and provided that some other position is not more directly conducive to recovery or to the avoidance of complications. A change of position will often add to the patient's comfort and promote sleep, and avoid some complications such as bedsores. In many abdominal cases, as for instance after appendicitis operations, stomach operations, operations for peritonitis, the sitting up position, or now generally called Fowler position, is of great advantage. Vomiting and chest complications are lessened and the fluids in the abdomen tend to gravitate towards the pelvis and drainage is facilitated. The respiratory movements are also freer. Care must be taken in this position that the patient is quite passive and that he does not need to retain himself in the position by active muscular effort. The patient's back is best supported by a bed-rest with pillows over it, and he may be kept from slipping down in the bed by a bolster placed under the flexed knees and attached by a strap or straps to the head of the bed. An alternative to this Fowler position is sometimes used which also promotes drainage: this is to leave the patient supine on the bed and to raise the head of the bed high on blocks or even on to chairs so that the patient lies obliquely with the pelvis in a dependent position. The prone position has also its uses. It forms an alternative to the dorsal position in some cases where bedsores are feared or have developed, or where a wound exists on the back or buttock, and it may also promote drainage from sinuses and abscesses on the front of the body, as for instance appendix abscesses in their later stages where drainage is inefficient. This position has been recommended for the treatment of children with spinal disease. I have recently successfully treated in this position a very large abscess of the leg, in which an opening had been made in front. It is not necessary to keep all operation cases in bed for many days. After such a severe operation as the removal of the tongue, many cases may be sat up almost immediately and put in a chair after the first few days. The tendency of tongue operations, however, is to become more severe. Shock is an almost necessary complication in bad cases, and for this the semi-prone position, keeping the head low and allowing drainage from the mouth, is most advantageous. We may next consider the question of the patient's diet. In the case of adults nothing at all will be required for the first five or six hours. There is no objection, however, during this time to rinsing out the mouth and giving sips of hot water. After this time larger quantities of water up to two ounces or even up to half a pint may be given from time to time. The use of an iced water is not so popular as it was, but it may sometimes check vomiting and may be tried for a short time with a view to relieving this troublesome complication. Other fluids besides water may be given. Tea is usually liked by the patient and has the advantage of being a stimulant. Albumen water, beef tea, Valentine's meat juice with or without soda water and raisin tea are all useful. Milk, plain or mixed with barley water or peptonised or citrated milk is a more substantial diet. In abdominal cases milk is, I think, best avoided at first till the bowels are open, as it is apt to disagree and it appears to be constipating and to promote flatulence. In babies, however, it is given as their natural diet, and may be started almost immediately after the operation after a preliminary trial with water. After an operation for intussusception, for instance, the child may be given a teaspoonful of a mixture of equal parts of milk and barley water on coming round from the anæsthetic, and in two or three hours it may be put to the breast. To adults after the first 12 or 24 hours, according to circumstances, bread-and-butter and a lightly boiled egg may be given, and later fish, chicken and meat may follow.

Rectal feeding.—Fluids may be given interruptedly or continuously by the rectum, and the patient may be nourished by this means alone. The following may be given by rectum :—A saline enema, one pint every three hours; continuous saline by rectal infusion drop by drop. The advantage of this method is that there is no distension of the bowel, and if successful none is expelled, every drop being absorbed. Saline solution plus glucose may be given continuously, and alcohol may be given if necessary. Small rectal enemata may be given from time to time, they should be two to six ounces in volume administered slowly through a catheter about every six hours. The bowel is washed out with plain water before the first feed and once in 24 hours while rectal feeding is continued. Plain milk, peptonised milk, eggs, beef tea, alcohol, coffee, etc., may be given.

Stimulants and drugs may now be considered. I myself still believe in the value of alcohol, such as brandy and champagne in moderate quantities, especially if the patient is accustomed to it, and I also consider that strychnine is useful at times.

Alcohol may be given by mouth or rectum. Morphia keeps the patient quiet and prevents shock and oozing of blood. In abdominal cases it should be avoided on the first night if possible, as it interferes with the action of the bowels and promotes flatulence. It may,

however, be necessary to give it and it may then be usefully combined with atropine. Aspirin and heroin are alternative drugs, and there are many others which will naturally occur to you.

Aperients.—It is most important to get the bowels open on the second or third day of operations almost without exception. Castor oil, liquorice powder, cascara, senna and calomel followed by salines may be given.

Nurse's report.—The nurse will be instructed to keep a chart, in which the temperature, pulse rate, respiration rate and number of stools is noted. The nurse should also keep an account of the character of the stools, and the amount and frequency of the urine. A specimen of the urine should be saved for examination, and in special cases the stools should be saved for inspection. The amount of liquid and solid food consumed, the amount of sleep and any special symptoms such as the following:—Pain, vomiting, rigor, hiccough, should be noted by the nurse.

Massage.—Massage is often of great service in the after treatment of a case. General massage may be made use of when the patient is confined to bed for any time as a substitute for exercise and to improve the general circulation and nutrition. Local massage is especially useful after cases of injury, such as joint injuries and fractures and in getting rid of results of chronic inflammation. It is most important to remember that massage may do harm. There are occasions when rest is better treatment, and this is so in the early treatment of injuries. Too early massage may cause the dislodgment of clot and embolism. It may displace fragments in fracture. It is an open question as to whether or not it will promote non-union in fracture. We do not yet know whether absolute rest and fixation, such as is obtained by operation, or slight movement, such as is obtained by other methods of treatment, is best in the long run for fractures. If the services of a specially skilled operator are available and if discrimination is used—for instance, if light stroking rather than vigorous kneading is chosen—it is probable that early resort to massage may in many cases hasten recovery. However, as I have said, harm may be done and recovery retarded, and great care must be exercised. In the later stages of chronic inflammatory processes when it is a question of the absorption of inflammatory products, massage is of very great value. Massage acts as follows:—It mechanically empties a congested part causing a fresh flow of blood to it. It stimulates the muscles to contract and empties the lymphatic spaces. Passive movements and active movements against resistance are also most useful. A daily sitting of about 20 minutes, which may be increased later, may be employed. What amounts to automatic massage occurs when we strap a joint, for instance, an ankle, and allow the patient to get about, or when, for instance, we put an elastic bandage such as a crêpe Velpeau bandage round the knee.

Bier's treatment.—This is useful in the treatment of the later stages of chronic inflammation as an alternative to or combined with massage. The principle is the production of localised hyperæmia. Passive hyperæmia may be induced by putting an elastic band, for instance, round the limb to constrict the vein. The application should be painless according to its advocates, but that it is so is by no means always the case, and though it appears to do good in some cases there are cases in which no such favourable result seems to follow. Active hyperæmia induced by means of the hot-air bath appears to be of great use in getting rid of the products of chronic inflammation, as for instance in softening the adhesions of a joint. Combined active and passive hyperæmia may be induced by the suction method with the special apparatus obtainable of all surgical instrument makers. The mode of action of this method is not quite clear, but it appears to be sometimes of benefit. Suction is useful in the treatment of sinuses by mechanically emptying them of their discharge as well as by the alteration in the circulation of their walls.

First dressing.—I wish to now consider the first dressing of a case. I would enter a plea for simplicity. I would strongly recommend the use of antiseptics, boiled instruments, gloves and sterilised dressings. It will thus be seen that I recommend a combination of the so-called antiseptic and aseptic methods. These are often referred to as antagonistic, but they are not so. Antiseptics must always be used, for instance, in rendering the skin sterile, but there is no need to irritate aseptic tissues with the needless application of strong germicides This is not to say that I should for a moment hesitate to wash out a contaminated wound with a strong antiseptic, or to apply undiluted carbolic acid or Lister's strong mixture to its surface. To come back to our first dressing after this digression, sterilised dressings and towels should if possible be provided by the nurse. Gloves and a few simple instruments, such as a pair of scissors, a pair of dissecting forceps, a pair of Spencer Wells forceps and a probe should be boiled and prepared for the surgeon and placed in sterile water or in 1 in 40 carbolic lotion. The nurse should then remove the bandage and perhaps the outer layer of wool. The surgeon should then arrange one or more sterile towels around his patient and quickly remove the rest of the dressing. A tube may be pulled out after from 24 to 48 hours as a rule. In some cases, however, it may be necessary to leave it in to give exit to discharge. The surroundings of the wound for some six inches should be painted over with tincture of iodine or with 1 in 500 mercury biniodide in spirit. This, in the case of an aseptic wound, is to guard against the infection of the wound from organisms in the skin. In the case of a septic wound it is to confine the infection of a wound to those organisms already in it. The fewer the number and variety of organisms in all cases the less their baneful effect. In the case of a wound without a tube which it is expected will run an aseptic course, the dressing is often left to the eighth or tenth day, when the stitches are removed forthwith at the first dressing. If a wound suppurates slightly, as when a large wound has been made, say after the removal of a breast in a fat patient, and a few stitches show signs of inflammation painting with iodine about the fourth or fifth day will often avoid the necessity of taking out sutures and allowing gaping of the wound. To avoid tension, a suture may be cut here or there without removing it and without disturbing the parts. A dry sterile dressing and bandage is applied after the wound has been dealt with. A little sterile wool in a pair of dissecting forceps is better than a brush for painting wounds. The practice of irrigating wounds should be avoided as far as possible. Sterile saline, or when the wound is foul, peroxide of hydrogen five or ten volumes are better than strong antiseptics as a rule. However, as I have said I am strongly in favour of avoiding irrigation as far as possible. The painting of wounds and their surroundings with spirituous lotions and the use of dry sterile dressings has also done away to a great extent with the necessity for the use of fomentations in the case of wounds and abscesses. While the warmth of fomentations promotes the circulation in the parts, and allows swelling to occur and thus relieves pain, it also tends to promote the septicity of the part by favouring the growth of organisms, and I am strongly of opinion that better results are obtained by dry methods. Fomentations are, however, useful in some cases, and experience will tell us when science must give way to empiricism. Baths are of great use in the treatment of some septic wounds, and in cases of cellulitis and whitlow, and burns particularly, great benefit may follow. The toxines locally produced are diluted and prevented from being absorbed and the temperature falls. I may say a word now as to surgical fevers. There are four surgical fevers. First, aseptic traumatic fever, which is due to the absorption of toxines which are not the result of micro-organisms. It occurs within the first 24 hours, rapidly subsides and the blood on examination is sterile. Septic traumatic fever or sapræmia or toxinæmia is the second variety and is due to the absorption of toxines produced by organisms acting locally in the wound. It quickly yields to treatment

of the wound, and again the blood is sterile on examination. The third variety of fever, septicæmia is more serious. Organisms have entered the blood, and we know no certain means of removing them. Local antiseptic measures, however, are still our first care, and hold out the greatest chances of success. A stimulating *regime* and the use of vaccines will, however, greatly contribute. The fourth variety of fever, pyæmia, is septicæmia with this clinical difference, that metastatic abscesses form as the result of septic emboli. Here again the treatment is the same as for septicæmia, but the ligature of a vein or removal of a thrombosed vein may isolate the septic focus and cut short the disease, or prevent a fatal termination. Pyæmia, it is well to remember, may be quite a chronic affection and require prolonged treatment, nourishing diet, fresh air, stimulants, etc. In all septic wounds a culture should be taken, so that serum or vaccine treatment may be instituted. Autogenous vaccines require time and care in their preparation, especially the synthetic variety. Heterogeneous or stock vaccines are available for use as soon as the orgnanism has been identified.

Complications.—I now propose to pass on and consider some complications commonly met with, and I will first mention shock. Shock is a complex of symptoms in which there are several factors; the effects due to injury, such as reflex cardiac inhibition, the lowering of the blood pressure from failure of the vaso-motor centre, the effects of the anæsthetic which are toxic and the toxæmia from sepsis, and there is also the psychic factor. There is and has been considerable controversy as to the mechanism of shock, and difference of opinion as to its proper treatment. Shock may be combined with the effects of hæmorrhage. The treatment of shock is partly preventive; such steps as the avoidance of mental excitement before operation, the giving of a little fluid, say half a pint of beef tea, shortly before operation, or a nutrient enema, or an injection of morphine or strychnine before operation according to the personal opinions and bias of the surgeon and anæsthetist may all help. The maintenance of the temperature of the body is highly important. When shock is established, warmth is still important, and probably the most potent means of relieving it is saline infusion, intravenous, rectal or subcutaneous. A little adrenalin may be added to the saline, but its effects are apt to be transient. Ergot has also been recommended to add to the saline. Strychnine and morphia hypodermically have both their advocates. As to which of these is the more appropriate I think we must wait for more light. Probably sometimes one, sometimes the other, is of use. The newest theories which would apparently do away with the old-fashioned stimulants have not yet satisfied me. In shock the head should be kept low and the limbs may be bandaged and belly compressed with a binder. Pituitary extract is sometimes given, but general measures are to my mind more important than giving the latest examples of organotherapy.

Hæmorrhage.—Hæmorrhage may be internal or concealed or external. Oozing from the wound may be treated by packing. If more severe, the wound must be opened up and the bleeding point tied. If the patient's condition is very bad, pressure in the form of plugging may be used. In internal hæmorrhage, such as that which occurs under a dressing or into the abdomen, or even into the rectum, a diagnosis is made from symptoms. These are increasing pallor and a so-called hæmorrhagic pulse: that is, a full, soft pulse. In shock the pulse is small and feeble, and in a combination of the two states the pulse is that of shock rather than hæmorrhage, though unfortunately it is the hæmorrhage which requires the active treatment. In hæmorrhage also there is gasping or sighing respiration referable to imperfect oxygenation of the tissues, attacks of blindness, buzzing in the ears, nausea and giddiness, sweating, and great restlessness, the patient throwing himself about, finally insensibility. In shock *per se* the patient lies still. As I have suggested, recognition of these cases of hæmorrhage is often difficult. The general treatment of hæmorrhage is rest and morphia, and to maintain the blood supply of brain by position, by bandaging the limbs, by transfusion or infusion, and even by artificial respiration. Oxygen inhalations are useful in this condition, as also in shock. In secondary hæmorrhage the treatment is that of primary or reactionary hæmorrhage, with in addition the disinfection of the wound and provision of drainage to prevent further septic processes.

Vomiting.—Vomiting varies in degree. Slight vomiting usually occurs after all anæsthetics. It is usually of short duration, and is usually treated by giving sips of hot water. As I mentioned earlier in my lecture, ice is sometimes useful in checking vomiting, particularly perhaps iced champagne, and this may be tried temporarily and abandoned if unsuccessful. If more severe we may give a draught of water in which there is some sodium bicarbonate which may be brought up immediately and clear out the stomach, or if more severe, the stomach may be washed out by a solution of sodium bicarbonate. Morphia and atropine given before operation apparently check vomiting, and morphia given after operation has the same effect. A weak solution of iodine, 10 to 20 minims of the tincture with half a pint of water, sometimes relieves vomiting. Other drugs recommended are: Cocaine, peppermint, bismuth, hydrocyanic acid, chloretone and bromides. Uræmia is sometimes the cause of the vomiting, and saline infusions will benefit this condition, and the skin and bowels must be made to act. Sometimes vomiting is caused by peritonitis, and repeated small doses of half grains of calomel will sometimes relieve this, which is apparently caused by meteorism. Vomiting is sometimes caused by post operative intestinal obstruction, which will require operative treatment.

Delayed chloroform poisoning is a complication to which attention has recently been drawn. It is by some attributed to the toxic effects of the anæsthetic, though others deny this. In this condition acetonuria is present. This gives a claret colour to the urine on the addition of ferric chloride. There is also persistent vomiting. Treatment is unsatisfactory, and the prognosis is grave. Jaundice and coma may supervene. Two drugs are advised, bicarbonate of soda and glucose. The stomach may be washed out with bicarbonate of soda, and the same solution may be given per rectum. Glucose may be given in water. Morphia must be avoided.

I now propose briefly to refer to some common operations.

Hernia.—In hernia operations the patient should be kept in bed for three weeks, and no straining or laborious work should be allowed for three months. The complications are:—Retention of urine; this may be relieved by the application of heat locally, or by use of the catheter. Flatulence, which will usually pass off when the bowels are opened, but it may be necessary to loosen the bandages. Swelling of the inguinal or scrotal region may occur from hæmorrhage or inflammation, but this will usually subside. It may, however, be necessary to open up the wound. Thrombosis of the veins of the leg sometimes occurs, and may be appropriately treated by rest. For this milk diet should be avoided and citrate of soda is a useful drug.

An Abdominal Case.—I will now speak of an abdominal case. The treatment of this class of case has been largely covered by my previous remarks, but a little repetition will not be out of place in such an important matter. The Fowler position will often be useful. Thirst may be relieved by fluids given by the mouth, or in the presence of vomiting by rectal saline. As to diet, nothing will be required for 24 hours except water, albumen water, tea, beef tea and Valentine's meat juice. Milk diet should be avoided until after the bowels have been opened. A turpentine enema is useful for meteorism, and a rectal tube may also help, but comfort will only be established after the bowels have been opened on the second or third day. Morphia should be avoided at first. Heroin and aspirin are preferable to quiet the patient, but on the second night, or even on the first, it is often necessary to procure sleep with morphia. The time in bed should, speaking generally, be short. Massage of the extremities is of use in promoting circulation: the toilet of the mouth

should be attended to, and sterilised food may sometimes appropriately be given. The dressing follows the lines of that of any other wound, and prolonged draining should be avoided.

Piles.—The patient often has some pain after an operation for piles. A half grain morphia suppository may be inserted into the rectum at the time of operation to ward off this, or an injection of morphia may be given.

These cases are liable to suffer from retention of urine and catheterisation may be necessary. The bowels are probably best opened on the third day by an aperient given the night before. When the action of the bowels is expected it is sometimes possible by giving a four-ounce enema of olive oil to avoid pain.

Hæmorrhage is a complication which may be severe, and it may be necessary to plug the rectum with a petticoated tube or catheter or to dilate the sphincter and tie the bleeding point.

Hæmorrhage may be concealed and only make itself known by its general symptoms. Stricture sometimes occurs and must then be treated by bougies. The mode of operating is sometimes responsible for these complications.

Varicose veins.—In cases of varicose veins a copious dressing should be firmly applied and the limbs slightly elevated. The patient should remain in bed three weeks as a rule and sometimes an elastic stocking or crêpe Velpeau bandage will be necessary to support the parts after operation.

Tonsils and adenoids.—The complication of hæmorrhage may be serious. Pressure will generally check it, but sometimes a bleeding point can be ligatured.

Care should be taken that the patient avoids catching cold.

Breathing exercises will tend to prevent the recurrence of adenoids.

Soft food will be necessary for some days.

Tongue cases.—The importance of position and the toilet of the mouth have been already alluded to.

Head cases.—Rest is one of the most important factors in the treatment of head cases. Quiet must be observed and a darkened room provided. Prolonged rest and avoidance of all intellectual work is essential. Tight bandaging of the head is uncomfortable, and the use of a triangular bandage will often be found useful.

Tracheotomy.—In these cases the patient will generally breathe better if the head is somewhat raised. In diphtheria cases the head should be kept low to avoid heart failure. A steam tent may lessen the liability to pulmonary complications. Moist gauze should be placed over the mouth of the tracheotomy tube, which should be kept clean with an alkaline solution, the inner tube being removed from time to time.

Thyroid cases.—In these cases drainage is important. Thyroidism is a most serious complication which sometimes supervenes. Saturating the patient with water by means of rectal infusion is a rational means of treating the symptoms which are toxic.

I have been unable, gentlemen, in this lecture to do more than refer to certain selected subjects. I have been obliged to omit reference to electrical treatment, treatment by X-rays and treatment by radium. All these matters have a bearing on after treatment, but I have been unable, chiefly through considerations of space, to include them in my lecture. I hope, however, I have said sufficient to impress you with the importance of the subject, and to suggest to you that further observation, experience and research will render more definite certain matters in which I have hesitated to be dogmatic, and with respect to which I have merely expressed my own opinion.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Eric Pritchard, M.A., M.D. Oxon., M.R.C.P.Lond., Physician to Queen's Hospital for Children, Physician to Out-Patients, City of London Hospital for Diseases of the Chest, Victoria Park. Subject: "The Uses of Dried Milk in Infant Feeding."*

ORIGINAL PAPERS.

A PLEA FOR EARLY OPERATION IN CASES OF UTERINE FIBROIDS. (*a*)

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,

Surgeon to the Chelsea Hospital for Women; Gynæcologist to the Prince of Wales's General Hospital, Tottenham.

The passive or expectant method of treating fibroids may be expressed in the now famous phrase "Wait and See"; that is to say, "wait for the menopause and see how matters will improve."

What reasons can be brought forward in favour of the expectant method? The possible reasons are these:—

1. That at the menopause the symptoms disappear and the fibroids tend to shrink.
2. That fibroids are not dangerous tumours.
3. That operation is attended by a high mortality, insomuch that the risk of operation is greater than the risk of leaving things alone; and that years of invalidism and disability are preferable to the running of this great risk.

1. The first reason is based on a succession of fallacies. The first is the assumption that the only bad symptom of fibroids is hæmorrhage. Really, hæmorrhage is only one symptom, and moreover it is a symptom only with some kinds of fibroids; the subperitoneal and many of the interstitial fibroids are not attended by any appreciable hæmorrhage. The other symptoms, pain, pressure effects, disability, and general weakness are not improved by the menopause and may be aggravated. The second fallacy is the assumption that the hæmorrhage caused by fibroids is only menstruation; such an assumption could only be excused if made by a layman. The hæmorrhage caused by fibroids continues for years after menstruation in the physiological sense has ceased; it may go on for years after the performance of double ovariotomy. The third fallacy is that fibroids shrink after the menopause; in many cases they actually increase in size; and in the few cases where a shrinkage occurs the effect may be worse than it was before, as a fibroid that lodged previously above the pelvic brim may become impacted in the true pelvis.

2. It is said that fibroids are not dangerous tumours. The same may be said of ovarian tumours, the danger of which lies in their possible complications. In the same way, the danger of fibroids, apart from the draining effects of hæmorrhage, lies chiefly in their possible complications, and I shall show presently by exact figures how numerous and serious the complications of fibroids really are.

Moreover, if we could say with truth that ovarian tumours are dangerous but fibroid tumours are not, there still remains the question: Can we be sure, in any given case, that the tumour is a fibroid? I shall show presently what dangerous results may follow such an assumption.

3. The argument based on the high mortality of operation would have had great weight 25 or even 20 years ago; this mortality has dwindled with the progress of abdominal surgery, and hysterectomy may now claim a recognised place, not only as an operation for saving life, but also as a means of relieving suffering.

My reasons for early operation are as follows:—

1. The age-incidence of fibroids is so varied that no importance can be attached to age as an indication for operation.

2. Early operation would often allow of a conservative myomectomy, when delayed operation necessitates hysterectomy.

3. In a large proportion of cases fibroid tumours are associated with pathological complications, many of which are of a dangerous nature.

4. Diagnosis is still so uncertain that grave conditions urgently requiring operation may be mistaken for simple fibroids.

5. The mortality attendant on the procedures of myomectomy and hysterectomy in the practice of ex-

(*a*) Abstract of a paper read at the Brighton meeting of the British Medical Association.

perienced surgeons has become so reduced that operation may legitimately be advised for the relief of suffering, when life is not directly threatened.

1.—AGE-INCIDENCE OF FIBROIDS.

I have particulars of the ages of 575 patients with fibroids operated upon by abdominal section. They were as follows:—

Under 25	3 cases,	or 0.5	per cent.
25-29	12 ,,	2.1	,,
30-34	57 ,,	9.9	,,
35-39	92 ,,	16.0	,,
40-44	150 ,,	27.1	,,
45-49	151 ,,	26.3	,,
50-54	73 ,,	12.7	,,
55-59	15 ,,	2.6	,,
60 or over	16 ,,	2.8	,,
Total	575 ,,	100.0	,,

This table bears out the accepted view that the greatest incidence of fibroids is between the ages of 40 and 50, since 55.4 per cent. of the cases were from 40 to 46. We may take the average age of the menopause as 48 or 49; consequently, we find 104 cases, or 18.1 per cent., requiring operation after the age when the menopause might be expected to have become established; and 31 cases, or 5.4 per cent., requiring operation 10 years after this date. The two oldest patients were aged 66. On the other hand, 161 patients, or 28.5 per cent., were under 40, and would have had to wait at least 10 years for the menopause; 72 patients, or 12.5 per cent., under 35 would have had to wait 15 years; 15 patients, or 2.6 per cent., under 30 would have had to wait 20 years; whilst 3 of the cases, aged 24, 23 and 18, would have had to wait about 26, 27, and 32 years respectively.

It seems evident, therefore, that it is quite time that the age question should be left out of consideration in relation to the operative treatment of fibroids, just as it is with ovarian tumours; with only this reservation, that whilst age should not affect the fact of operation, it may properly influence its nature; that is to say, that whilst hysterectomy should nearly always be done after the age of 45, myomectomy should always have the preference before the age of 30; and from 30 to 45 the decision should depend on the position, character and number of the tumours.

2.—CONSERVATIVE MYOMECTOMY.

There can be no question that the ideal treatment of fibroids is to remove the tumour and leave the uterus. Such a course is, of course, impossible or inadvisable in the case of multiple fibroids and cervix-fibroids, and in many cases of large fibroids; but when it is practicable it has two important advantages, first, because the uterus may be capable of subsequent child-bearing, and, secondly, because some women feel mutilated and unsexed by the removal of the uterus. With fibroids of long standing, the chances of doing myomectomy are obviously less than with those of more recent development; and it is my practice, when dealing with early fibroids in young women, to aim at myomectomy rather than hysterectomy, although myomectomy may be not only possible but also the better operation sometimes in older women.

3.—COMPLICATIONS OF UTERINE FIBROIDS.

I have analysed the complications present in 580 consecutive cases of uterine fibroids operated upon by abdominal section, and the results are shown in the subjoined table. They include 495 cases of hysterectomy, 80 cases of myomectomy, and 5 cases in which the fibroids were merely incidental to some graver condition and were left alone.

AN ANALYSIS OF THE PATHOLOGICAL COMPLICATIONS PRESENT IN 580 CONSECUTIVE CASES OF UTERINE FIBROIDS OPERATED UPON BY ABDOMINAL SECTION.

I. *Uncomplicated cases*		170
II. *Complicated cases*		
1. *Degenerative changes in fibroids*—		
Necrobiosis	50	
Red degeneration	9	
Fibro-cystic degeneration	11	
Calcareous degeneration	8	
Necrobiosis and calcareous degeneration	5	
Sloughing	3	
Sloughing associated with bowel fistula	1	
Suppurating fibroid: ovarian abscess: septic peritonitis	1	
		88
2. *Inflammatory disease of the tubes*—		
Salpingitis and resulting adhesions	47	
Hydrosalpinx	16	
Hæmatosalpinx	2	
Pyosalpinx	18	
		83
3. *Ovarian disease*—		
Cystic ovaries	111	
Ovarian tumours	58	
		169
4. *Malignant disease*—		
Carcinoma of the uterus	5	
Carcinoma of the ovary	4	
Carcinoma of the sigmoid	4	
		13
5. *Adeno-fibroma of the uterus*		12
6. *Pregnancy*		8
7. *Tubal pregnancy*		1
8. *Uterine displacements*		36
Total Complications, 410 out of 580 cases = 70.5 per cent.		580
Dangerous complications—		
Degenerative changes	88	
Suppurative conditions	18	
Ovarian tumours	58	
Malignant disease	13	
Total dangerous complications, 177 out of 580 cases = 30.5 per cent. of all cases and 43.1 per cent. of the cases of complications.		

It will be seen from the table that complications were present in 70 per cent. of cases. Some of these complications were relatively unimportant as far as the danger to life is concerned; for example, non-suppurative disease of the tubes and uterine displacements are not dangerous conditions, though they may induce a great deal of suffering and invalidism; cystic disease of the ovaries may be unimportant, though it probably represents the early beginnings of ovarian cysts; adeno-fibroma is not in itself dangerous, though it may predispose to the development of adeno-carcinoma of the uterus. Pregnancy may be regarded as a purely accidental complication, and some writers on the subject rather make light of it; for my own part I consider it may be one of the most formidable of the complications of fibroids.

There are, however, other complications that are intrinsically dangerous, including degenerative changes in the fibroids themselves, suppurative conditions in the pelvis, ovarian tumours and malignant disease; and these four groups make up no less than 30.5 per cent. of all the cases of fibroids, and 43 per cent. of the cases of complications.

In view of the tendency that still exists to advocate waiting for the menopause, it appeared to me that it would be interesting to compare the complications in cases under the age of 50 with those in cases over that age, and such a comparison is shown in the following table:—

A COMPARISON OF THE COMPLICATIONS IN PATIENTS UNDER 50 AND OVER 50.

	Under 50. Cases.	%	Over 50. Cases.	%
I. *Uncomplicated cases*	141	29.6	29	28.2
II. *Complicated cases*:—				
1. Degenerative changes	69	14.5	19	18.1
2. Inflammatory conditions, non-suppurative	54	11.3	11	10.8
Inflammatory conditions, suppurative	15	3.1	3	2.9
3. Ovarian Disease. Cystic ovaries	99	20.8	12	11.6
Ovarian Disease. Ovarian tumours	46	9.6	12	11.6
4. Malignant Disease	6	1.2	7	6.8

	Under 50. Cases.	%	Over 50. Cases.	%
5. Adenofibroma ..	10	2.1	2	1.9
6. Pregnancy (Uterine and tubal)	9	1.9	0	0.0
7. Displacements ..	28	5.9	8	7.8
	477	100.0	103	100.0

Total complications, under 50, 336 out of 477=70.4 %
" " over 50, 74 out of 103=71.9 %
Dangerous complications .....under 50, 136 out of 477=28.5 %
Dangerous complications .....over 50, 41 out of 103=39.8 %

It will be observed that whilst the total number of complications is only slightly greater above the age of 50, *viz.*, 71.9 per cent., as against 70.4 per cent. under 50, the tendency to dangerous complications is markedly greater, rising from 28.5 per cent. under 50 to 39.8 per cent. over 50. Consequently the incidence of dangerous complications is in itself a strong argument against the "wait and see" policy.

4. THE UNCERTAINTY OF DIAGNOSIS.

It is very easy to make mistakes in diagnosing uterine fibroids, and the mistakes are of two kinds. In the first place, one may diagnose only fibroids and find some other serious condition present also, such as uterine or ovarian carcinoma, ovarian tumours or pus-tubes; in the second place the condition may not be a fibroid at all, but carcinoma of the uterus or a solid ovarian tumour.

The first kind of mistake is the more liable to occur, and I could recount numerous instances among my own cases. When a patient presents the history and symptoms of fibroids, including progressive menorrhagia and metrorrhagia, and various hard and irregular swellings are present in the pelvis and lower abdomen, it is a not unnatural inference that all these swellings are fibroids; and indeed, often there is nothing in the history of the case to lead one to think otherwise. In this way I have found pus-tubes and ovarian tumours present in a number of cases; the table of complications show 18 cases of pus-tubes, 58 cases of ovarian tumours, four cases of ovarian carcinoma, and 2 of uterine carcinoma, and in most of these cases the complication was not suspected beforehand.

Of mistakes of the second kind I will relate only four well-marked examples. One was a patient of 75 with a hard, solid tumour filling the pelvis. I diagnosed uterine fibroid, and made arrangements to operate with all possible speed to minimise shock. It turned out to be an ovarian fibroma, the removal of which was so simple that the whole operation took just ten minutes. I saw the patient three years later, when she looked very well. The second was a patient aged 60, with an enormous solid tumour. Dr. Champneys had seen her ten years before and diagnosed uterine fibroid and advised waiting for the menopause. Meanwhile the tumour grew steadily, and after some years she was advised that it was too large for removal. When I saw her, I also diagnosed uterine fibroid and advised operation, as the patient was incapacitated; it turned out to be an ovarian fibro-adenoma, weighing 30 lbs. The operation was exceedingly simple, and the patient remains in excellent health four years after the operation.

In the third case the patient had been seen by Dr. Herman, who diagnosed uterine fibroids; he asked me to take her into the Chelsea Hospital for Women for operation, and when I saw her I concurred in the diagnosis. It turned out, however, to be a mass of extensive malignant disease in the pelvis too far advanced to allow of removal.

The fourth case was a patient of 39, stout and well-nourished, with a history of metrorrhagia. The uterus was about the size of a man's fist, the cervix looked healthy, the os externum was nulliparous. When the uterus was removed there was no fibroid, but a large mass of carcinoma occupied the body of the uterus, and an apparently separate endocervical growth of carcinoma extended down nearly to the external os. The operation took place only a few days ago, on the 14th of July.

5. THE DIMINISHING DEATH-RATE OF HYSTERECTOMY AND MYOMECTOMY.

It may be laid down as a surgical axiom that highly dangerous operations are justified only when undertaken for the saving of life; whilst operations that are attended with a small risk may legitimately be undertaken for the relief of suffering.

Twenty-five years ago hysterectomy was a highly dangerous operation, with a mortality ranging from 25 to 40 per cent., and the operation of myomectomy was unknown. Clearly, with such a mortality, hysterectomy could be advised only when life was seriously threatened, and when it was only a case of suffering and disablement, it was best for the surgeon to hand the patient over to the priest, who should prescribe patience and fortitude; for it is, after all, better to live as an invalid than to die cured.

We cannot base the treatment of fibroids to-day on the mortality of twenty-five years ago; hysterectomy, as we understand it, is an operation radically different from that which was done then, and the following table shows the phenomenal diminution of mortality It will be sufficient for my purpose to record the results of hysterectomy for fibroids at the Chelsea Hospital for Women for five successive quinquennial periods, and my own results of hysterectomy for fibroids and fibrosis, and of myomectomy during the sixteen years that I have been performing these operations. The results in other hospitals and of other operators would be somewhat similar.

TABLE 5.—MORTALITY OF OPERATIONS FOR HYSTERECTOMY AND MYOMECTOMY.

1. Analysis of results of Hysterectomy for Fibroids at the Chelsea Hospital for Women for 25 years, from 1886 to 1910:—

1886–1890,	14 cases,	5 deaths,	mortality	35.7%
1891–1895,	12 ,,	5 ,,	,,	41.6%
1896–1900	150 ,,	16 ,,	,,	10.6%
1901–1905,	345 ,,	18 ,,	,,	5.2%
1906–1910,	487 ,,	9 ,,	,,	1.8%

2. Analysis of Author's results of Hysterectomy for Fibroids and Fibrosis for 16 years, from July, 1897, to July, 1913:—

1897–1900,	10 cases,	0 deaths,	mortality	0%
1901–1905,	89 ,,	6 ,,	,,	6.7%
1906–1910,	234 ,,	7 ,,	,,	3.0%
1911–1913,	217 ,,	2 ,,	,,	0.92%
Total ..	550 ,,	15 ,,	,,	2.7%

Author's results of Myomectomy:—
1898–1903, 19 cases, 2 deaths.
1904–1913, 61 ,, 0 ,,
Total .. 80 ,, 2 ,, mortality 2.7%

We see from this table that in the last quinquennial period, to the end of 1910, at the Chelsea Hospital for Women 487 hysterectomies were performed with a mortality in all cases, serious as well as simple, of 1.8 per cent.; during that period my own mortality was 3 per cent. for 234 cases, and in the last 2½ years I have had two deaths in 217 cases, a mortality of 0.92 per cent. Previous to these two deaths there was a series of 110 consecutive recoveries; and there was a series of 90 between the two.

The indications for an operation whose mortality is 30 per cent. are necessarily very different from the indications when the mortality is only 1 or 2 per cent. My contention is that whereas formerly hysterectomy could only be advised in urgent cases of life and death, it is now indicated in the far more numerous cases in which patients suffer constant pain and discomfort and are chronically incapacitated by the drain of hæmorrhage and the pressure of tumours on surrounding organs; and further, that the relief of patients in these early stages is not only curative of chronic ill-health but also preventive of many dangerous complications.

How often one has had to reflect, "If only this

operation had been done years ago, how much suffering would have been saved, and present danger or fatal disaster averted!"

To sum up, early operation allows of conservative procedures whereby the uterus is preserved, in many cases where delay entails the inevitable sacrifice of the uterus; it saves patients from many years of suffering and disablement, enabling the workers to earn their living and the leisured to enjoy life; it averts many complications that are the direct result of fibroids, and makes it possible to deal with independent complications that would otherwise be overlooked; it saves patients from the serious consequences of mistaking, for fibroids, tumours that are even more dangerous; and it prevents the health and life of patients from being sacrificed to the exploded fallacy of the "waiting for the change of life."

THE PRESENCE OF COMPLEMENT IN INFECTIOUS DISEASES.

By WILLIAM C. GUNN, M.D.

Two classes of substances are concerned in the production of immunity in an organism, the immune body, which is definitely recognised as being specific, and the complement, with regard to the specificity of which differences of opinion exist. Complement has been defined as that labile substance of normal serum which is taken up by the combination of an antigen and its antisubstance. While different kinds of complement exist in the serum it has been proved that, provided sufficient immune body and its antigen are present—a condition which probably exists in the most active stages of all acute infectious diseases—all the types of complement are absorbed in the reaction. It is because of this common action displayed by the different complements that it is possible, by the estimation of one type—the hæmolytic—to measure the total complement content of the serum.

In applying the hæmolytic test in the series of cases reported on, 8-10 c.c. of the patient's blood, yielding 4-5 c.c. of serum, were used for each examination. Ox corpuscles were used as antigen, and immune body was obtained by immunising a rabbit with successive injections of washed ox corpuscles in quantities of 5 c.c., 10 c.c. and 15 c.c. at intervals of ten days. By mixing measured quantities of the rabbit's serum and of a suspension of ox corpuscles in saline solution, and incubating for thirty minutes at 37 degs. C. a sensitised suspension of ox corpuscles was obtained. Of this 1 c.c. was put into each of twenty-four test tubes, and to each was added a quantity of the patient's serum ranging from 0.02 to 0.28 c.c. The test tubes were then incubated for an hour, and the complement content of the serum was determined by the test tube in which complete hæmolysis occurred.

While the age of the patients did not appear to have much influence on the results, there were considerable differences in the amount of complement present in the different individuals examined, these differences being more marked in the acute stage of the fever than during convalescence. It may reasonably be inferred that immune substances are smaller in amount when prostration and toxæmia are most marked than when recovery is taking place. It may also be assumed that the more immune body is present in the serum the greater will be the amount of complement required in order that the former may be used to the greatest advantage of the patient. The presence of the infecting agent in the body stimulates the production of both antibody and complement, but the response made by each is not the same. The immune body and the complement are independent of each other.

The results obtained in enteric fever may be summarised as follows:—(1) Complement is always present during enteric fever, and is, as a rule, much more abundant throughout the period of pyrexia than during convalescence. (2) Diminution in the amount of complement in favourable cases seems to coincide with the production of immune body as shown by the condition of the patient. Probably when immune body is being produced the complement is fixed and there is then less available for the hæmolytic test in vitro. (3) Complete immunity is not established in all cases at any definite time after the temperature has settled, and it does not seem to bear any definite relation to the degree of severity of the attack; but it would appear to depend to some extent on the length of the period of illness, immunity being established sooner after a brief than after a long illness. (4) Severity of the attack bears some relation to the amount of complement present during the fever. In patients who are very ill complement, as well as immune body, may be produced slowly or only a weak type of complement may be present. In patients who are moderately ill a relatively small amount of complement seems to indicate the presence of a considerable amount of immune body, but not sufficient to terminate the attack. In the intermediate type of illness, which is most common, a large amount of complement is usually found. (5) The variation in the amount of complement during some prolonged types of primary fever seems to indicate that the terminal portion of the pyrexia may be of the nature of a recrudescence. (6) During relapses complement is increased and diminished when recovery is taking place. The diminution appears sooner after a relapse than after a primary attack. This might mean that immune body is produced earlier than in the original attack. (7) Death from enteric fever appears to be due chiefly to absence of immune substances. Complement is sometimes very abundant in fatal cases, but at other times only a weak type may be present. (8) The results show that complement and immune body are not produced in any fixed ratio to one another.

Observations made in erysipelas yielded the following results:—(1) In the majority of the cases examined complement was present in greater amount during the acute stage of the illness than during convalescence. The clinical course of these cases supports the view that this diminution coincides with the production of immune substances. (2) No definite relation was found to exist between the severity or duration of the illness and the period at which immunity in the primary attack is established. (3) The greatest amount of complement present in any case bears no relation to the severity or duration of the illness. (4) This amount is considerably less than that observed in enteric fever, which suggests that the production of immune substances occurs comparatively early in erysipelas. (5) An increase in the amount of complement observed in some cases during canvalescence is possibly due to an early diminution in the amount of immune substance present. It is well known in this connection that the immunity established by an attack of erysipelas is often of short duration. (6) Irregularity in the amount of complement present during illness may indicate a certain degree of instability in the immunising mechanism, as is shown by the clinical course of a case of erysipelas migrans. (7) The amount of

(a) Paper read at the Glasgow Medico-Chirurgical Society.

complement present in fatal cases has been found to be above the normal average.

Summary of Results in Diphtheria.—(1) In 10 severe cases (7 faucial and 3 faucial and nasal) there was a greater amount of complement present during the acute stage of the illness than during convalescence. (2) In 3 severe faucial cases complement was greater in amount during convalescence than during the acute stage. (3) In 4 moderately severe cases (2 faucial and 2 faucial and nasal) little or no complement was found. (4) In 2 fatal hæmorrhagic cases complement was relatively great in amount shortly before death. (5) In 13 of the cases the diminution in the amount of complement occurred during the period in which the throat was healing and the toxæmia disappearing. In 4 others a varying degree of increase in the amount of complement was observed at this period. (6) In some instances the amount of complement showed a tendency to lessen within twenty-four hours after the administration of antitoxin, and there seemed to be a tendency for the greatest diminution to occur after the injection of a large dose.

Summary of Results in Scarlet Fever.—(1) In 6 mild cases no definite type of variation in the amount of complement occurred. (2) In 10 more severe cases a diminution was observed during the pyretic period, with, in 6 of these cases, a more or less marked increase during convalescence. (3) In 4 cases of scarlatinal nephritis complement was almost absent or was present in small amount only. (4) In 2 fatal malignant cases a large amount of complement was present at the time of death.

In 6 cases of measles which were investigated complement was present, but such slight variations as occurred in its quantity appeared to follow no definite rule.

In typhus (3 cases observed) complement seemed to be less in amount during the priod of illness than during convalescence. One of the cases died from a pyogenic infection of the urinary tract, having apparently recovered from the typhus infection. The largest amount of complement was found in the specimen obtained about the time of death, and this is in accord with the results obtained in other infectious diseases.

In lobar pneumonia complement was found to be present in greater amount during the acute stage of the illness than during the period of convalescence.

ANATOMY AND THE INTERPRETATION OF CLINICAL OBSERVATIONS.

By S. J. ROSS.

Senior Assistant Surgeon, Bedford County Hospital.

The publication of these brief observations is due to the fact that a few months ago a colleague intimated to me his opinion that a knowledge of anatomy was a hindrance rather than a help to the general practitioner. Possibly such knowledge may prove a stumbling-block to a nervous operator, but it is essential to the general practitioner.

Even the common nævus, essentially of vascular origin, has a nerve distribution. One cannot see a case of herpes without being reminded of the course of some sensory nerve, and, indeed, it is a matter of the greatest interest to identify the nerve which is affected.

It is not my intention to give my readers a classified list of illustrations, but to choose my illustrations at random from my note-books.

A man, æt. 54, complained of pain in the area of skin supplied by the eighth and ninth dorsal nerves on the right side. His other complaints were of flatulency and constipation. He had no abdominal tenderness, and had never had jaundice. I remembered that the gall bladder was supplied by these segments, and so I advised an exploratory laparotomy, informing him that in all probability he had stones in his gall bladder. We subsequently removed four stones from his gall bladder. The pain disappeared.

A man, æt. 76, complained of sciatica of the left leg and loss of flesh. Examination revealed extensive carcinoma of the sigmoid. He had had all kinds of treatment, from blistering to ionic medication, naturally without benefit.

A boy, æt. 10, complained of intense pain on the inner side of the left knee. A back splint was supplied, and, subsequently, a plaster of Paris bandage. No improvement followed. The mischief was in his hip-joint, and at the operation we discovered the joint disorganised, and the ligamentum teres, along which a branch of the obturator nerve runs, in a state of disorganisation.

A youth, æt. 19, complained of pain at the outer side of the right thigh. The area involved corresponded to the distribution of the external cutaneous nerve. The pain was induced by standing and walking. Therefore it was a case of neuraigia paræsthetica, a form of neuralgia which we know is frequently associated with flat-foot; and so it proved to be in this case. Valgus pads relieved the pain.

A man, æt. 37, fell through a plate-glass window, sustaining a wound across the flexor aspect of the right wrist. When I saw him he was keen on the scent of compensation, and gave me an anatomical description of the symptoms resulting from a cut median nerve. His lesson was not word-perfect, because, on testing his sensation, I found that he had apparently lost sensation over both the extensor and flexor aspects of his four fingers, and, upon examining the position of the wound, I discovered that his median nerves could not possibly have been severed.

Readers may say that I should have examined the wound first. Experience has taught me, when dealing with a compensation case, to let the patient talk first and make your own observations afterwards. If you listen patiently and carefully you not only gain his confidence, but you learn the innermost workings of his mind—a very important point if you are called to give evidence in a law court.

A boy, æt. 12, complained of intense pain over his left buttock. As this region is supplied by the lumbar plexus, we examined his spine and discovered lumbar caries and a left psoas abscess.

We are apt to regard pain as of peripheral character.

A woman, æt. 37, complained of pain on the left side of the neck extending to the middle of the sterno-mastoid muscle. There were no glands or local tumour present, but a gumma of the left sterno-clavicular joint, irritating the descending branches (sternal and clavicular) of the cervical plexus (third and fourth cervical nerves).

A carter, æt. 27, complained of pain in the region supplied by the great occipital nerve. Twelve months previously, after a Saturday night revel, he had received a cut head. This scar lay across the great occipital nerve. Freeing the scar cured the pain.

These few cases, which I could easily treble, prove the absolute necessity of keeping up our anatomical knowledge if we hope to correctly diagnose our cases, and do not rest contented with giving a name to a symptom complex, and, having labelled the symptoms, treat the patient empirically.

THE VALUE OF ASPIRIN IN OPHTHALMIC WORK.

By JOHN ALLAN, M.D., D.P.H.,
Ophthalmic Surgeon, Battersea General Hospital.

In some quarters it is firmly believed that local treatment holds the premier place in dealing with affections of the eye. No doubt local measures are of undoubted value in numerous eye conditions, but it is also true that internal medication fills a most important *rôle* in ophthalmic therapeutics. In some cases local treatment may suffice; in others, the administration of drugs internally is all that is required; but in quite an appreciable percentage of cases combined treatment, local and general, will afford the best results.

The list of drugs which may be employed internally in ophthalmic work is no doubt fairly large, but when the matter is examined more carefully, it will be found that very few drugs have earned for themselves the distinction of universal acceptance. A drug which is of undoubted service in eye work and which might with advantage be more generally employed, is aspirin. It may not be without interest to examine some of the conditions in which this drug may be administered. Aspirin belongs to the salicylate group, and it might be inferred that it is indicated chiefly in those cases where anti-rheumatic medication is called for. This is certainly true, but its sphere of usefulness is by no means so limited.

Iritis is of rheumatic origin in a certain percentage of cases, and I have found that such cases respond well to aspirin. For example, J. G., a post office employee, æt. 30, came under observation for an attack of iritis of the right eye. Specific infection was denied. The man had had rheumatic fever twice, the last attack having occurred six months previous to the onset of the iritis. The eye was acutely inflamed and the subjective and objective symptoms were typical of acute iritis and need not be detailed. The local treatment consisted in frequent lavage with boric acid lotion and the instillation every four hours of atropine drops (4 grains to the ounce). Leeches were applied to the right temple. The patient was put to bed and aspirin (gr. xxx.) was ordered every four hours. After two days the dose of aspirin was reduced to gr. xv. four-hourly, and at the end of a week the patient was having the drug in 10 grain doses three times a day. The boric lotion and atropine drops were continued. This treatment was sufficient to effect a cure. In iritis of specific origin anti-syphilitic treatment is, of course, indicated and I always deal with such cases by prescribing mercury and iodides. But I am convinced from personal observation that an occasional dose of aspirin, say 20 grains at bedtime, acts well in some of these cases.

In the treatment of sympathetic ophthalmia, the administration of large doses of sodium salicylate has found favour with many ophthalmic surgeons, and I can testify to the value of this medication in such circumstances. Here again aspirin may prove invaluable, and I can recall one case of sympathetic ophthalmia in a child in which aspirin was prescribed with benefit.

In various eye injuries aspirin may also be used and many such cases which are not responding well to treatment improve in a most remarkable manner when submitted to aspirin medication. In certain eye operations there may be some subsequent iritis and the drug under discussion will frequently afford relief when local treatment by itself fails to satisfactorily clear up the inflammatory condition. There are other eye affections, *e.g.*, episcleritis, cyclitis, etc., in which aspirin may be utilised, but I think I have said enough to support my contention that this drug is a valuable asset in ophthalmic practice.

In my opinion, the drug can be prescribed with perfect safety in large doses. I have administered it in hundreds of cases, and, with the exception of tinnitus in one or two cases, and of rather profuse sweating in a few others, I have noted no untoward symptoms. Some cases have been reported in which somewhat alarming symptoms have followed the use of aspirin, but it would be interesting to know if aspirin were really the drug at fault. Aspirin is pure acetyl-salicylic acid, but it is unlikely that all the acetyl-salicylic acid on the market is of the same standard. I can only say again that my own experience leads me to believe that aspirin or pure acetyl-salicylic acid is a safe remedy which, apart from the possibility of idiosyncrasy on the part of the patient, is not likely to give rise to grave symptoms.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

PIROGOFF'S AMPUTATION OF THE FOOT.—MR. WILLMOTT EVANS operated on a man, æt. 28, whose foot had been crushed by the wheel of a wagon passing over it. On admission the anterior two-thirds of the left foot had been completely pulped, several toes were missing, and the skin was extensively torn, but the heel was intact and there was no bleeding. It was obvious that an amputation in the neighbourhood of the ankle was imperative, and Mr. Evans decided to perform Pirogoff's amputation.

The patient was anæsthetised. An Esmarch tourniquet was placed round the thigh, and the part was well swabbed with a two per cent. solution of iodine. An incision was then made straight across the front of the ankle-joint, extending from the tip of the external malleolus to a corresponding point on the inner side—that is to say, about three-quarters of an inch below and behind the tip of the internal malleolus. This incision went right down to the bone. A second incision was then made; it started from and ended at the same points as the first incision; it passed downwards and forwards, making an angle of about 45° to the horizontal and passing straight across the sole of the foot. This incision was also down to the bone. The foot was then forcibly extended, and the ankle-joint was opened from the front, and a knife was inserted between the astragalus and the malleoli to divide the lateral ligaments of the ankle-joint. By still further extending the foot the joint was completely opened; the posterior ligament was then divided, and the saw was inserted and the os calcis was divided in the line of the plantar incision. The tissues around the malleoli were turned upwards sufficiently to allow the lower end of the tibia and fibula to be sawn off. The saw-cut was so directed as to remove the whole of the articular cartilage, and at the same time it passed from before backwards and a little upwards. All bleeding vessels were tied when the tourniquet was removed; nerves and tendons were cut short, then the os calcis was fastened with silver wire to the tibia, and the wound was sutured.

Mr. Evans said that Pirogoff's amputation was, in his opinion, decidedly the best method of dealing with injuries to the foot for which amputation at the ankle is required, but in which the heel has escaped. It

should never be employed for disease, for the calcaneum is one of the bones most frequently involved in any tuberculous process affecting the foot. The merits of the stump left after Pirogoff's amputation are these: First, that the part walked on is suited for bearing pressure, for it is a portion of the sole which habitually touches the ground; secondly, the stump is ready for use at an earlier period than after any other amputation in this region. The modifications of the original procedure are three in number: first, the plantar incision is made to slope more forwards; secondly, the tibia and fibula are sawn, not horizontally, but slightly upwards as well as backwards; the object of these two modifications is to allow the cut surface of the calcaneum to come into apposition with the bones of the leg with less rotation than was required by the original method, so that the patient still walked on the sole. The third point of importance is that the calcaneum is wired to the tibia; this prevents movements between the bones and ensures a more rapid union. The only objection which has been advanced against the operation is that the stump is difficult to fit with an artificial foot. This objection seemed to him to be not valid, for he had experienced no difficulty in obtaining suitable appliances for his cases.

The wound healed rapidly and, except at one point, by first intention, and the patient was able to leave the hospital three weeks after the operation.

ROYAL LANCASTER INFIRMARY.

"Chronic Abdomen"—Mr. A. S. Barling operated on a woman, æt. 37, who for five or six years had suffered from abdominal pain chiefly centred about the cæcal region. Discomfort was constant, and pain, of an aching character, sometimes becoming acute and griping, more often present than not. It was worse during menstruation. Indigestion and flatulent distension of the bowels were also very common. A year ago, being seven months pregnant, she had obstruction for three days. Labour was induced and her symptoms quickly disappeared. On getting about again she very soon reverted to her former state.

The abdomen was opened through the right rectus. Many adhesions were found about the cæcum, and a badly adherent appendix 6 in. in length was removed. Examination of the ascending colon revealed a well-marked Jackson's membrane across its middle, causing a distinct kink. The membrane was divided and the cut edges carefully brought together with continuous sutures. The right ovary was as large as a Tangerine orange, and, being also cystic, was taken away.

Mr. Barling said that this was a typical example of what he had ventured to call the "chronic abdomen." It would be noticed that three different conditions were present, each of which was capable of accounting for the symptoms, and which, with the exception of the ovary, did not admit of diagnosis by any external examination.

The patient made an uneventful recovery.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

Meeting held Friday, February 13th, 1914.

The President, Dr. Charters J. Symonds, in the Chair.

Exhibition of cases in which splenectomy has been performed, or is contemplated, for disease, and discussion.

Sixteen cases of various forms of splenic enlargement were shown.

Dr. T. R. Whipham described four cases of splenic anæmia occurring in the father and three children of one family. He said that the incidence of this disease in two successive generations was very rare. The blood counts in them all were very similar, and the differential counts were practically identical. The lymphocytes and polymorphonuclears were correspondingly increased. The red cells were diminished and showed alteration in size, shape and nucleation. Another feature was eosinophilia, which could possibly be explained by the presence of a tape-worm in the father, but this was not so in the case of the children. He did not think that splenectomy was indicated for the father and a boy, who were in a fairly good state of health, but it had to be considered in the cases of the two other children (girls), who had marked anæmia and whose blood had deteriorated lately.

Mr. Percy Sargent showed a case of this disease after splenectomy. The patient, a girl, æt. 10, recovered from the operation, but six weeks later severe hæmatemesis occurred, and was followed by pyrexia and a varying amount of diarrhœa. The leucopenia was replaced by a considerable leucocytosis, but now, 13 months later, the blood had become normal, except for a slight increase of lymphocytes.

Mr. Geoffrey Hoffmann showed a case in a girl, æt. 12., from whom the spleen had also been removed. She had had hæmatemesis, epistaxis, purpura and melæna. The blood condition rapidly improved after the operation, and was still normal more than two years later.

Dr. Herbert French and Mr. Philip Turner showed a boy, æt. 5, whose case had been diagnosed as one of splenic anæmia of the infantile form, and who had rapidly recovered after splenectomy. A younger sister had a similar condition. He thought that the cause was probably syphilis, although antisyphilitic treatment had been unsuccessful.

Sir J. Bland Sutton advised splenectomy for the boy shown by Dr. Whipham. He thought that the result would be so good that it would afterwards be performed for the other cases of the family, the father excepted.

Mr. G. R. Ward disagreed with the diagnosis in the family group of cases. There was slight yellowness present due to blood destruction. The blood counts were typical of acholuric jaundice.

Dr. Parkes Weber agreed with Dr. Ward. If enlargement of the spleen occurred in a family in which adults as well as children were affected and was associated with anæmia, the condition was the same as that of hæmolytic jaundice, although jaundice might be present. No member of the family had leucopenia, which was strong evidence against splenic anæmia. Dr. French's cases belonged to a class which formed a group in themselves, in which cachexia, anæmia and splenic enlargement were associated with congenital syphilis, but antisyphilitic treatment did no good. They were not syphilitic, but were engrafted on a syphilitic base.

Sir William Osler said that the remittent fever accompanied by eosinophilia in Dr. Whipham's case indicated trichinosis, in which the eosinophilia often persisted. He also considered them examples of a form of hæmolytic jaundice. He referred to the importance of distinguishing cases of congenital syphilitic cirrhosis of the liver accompanied by enlargement of the spleen and hæmatemesis from splenic anæmia. He had long urged the value of excision of spleen in the latter, and it had been shown emphatically that this procedure produced a cure.

Dr. C. R. Box said that the case shown by Dr. French had formerly been under his care, and he regarded him as an example of von Jaksch's anæmia. The case showed that splenectomy did good in that condition. He had treated a similar case in which there was slight increase of fragility of the red cells. The spleen was removed, and though the patient died from an abscess in the stump, the blood condition improved greatly. There was a connecting link between cases of von Jaksch's anæmia of acholuric jaundice and of the splenic anæmia of adults.

Cases of acholuric and hæmolytic jaundice were shown by Dr. Essex Wynter and Sir J. Bland-Sutton, Dr. Hugh Thursfield, and Sir Bertrand Dawson.

Dr. Wynter and Sir J. Bland-Sutton's case was

one of congenital acholuric jaundice, which had recovered completely and rapidly after splenectomy.

Dr. Wynter said that he had found that in such cases it was usual for an excess of cells to be present after removal of the spleen, but this afterwards subsided. It looked as though there was a compensatory over-production which persisted for a time. In considering the advantages of splenectomy one ought to regard not only the possibility of a fatal issue, but also the chance of enjoying the full functions of life.

Dr. Thursfield's case was also one of congenital acholuric jaundice which had recovered after splenectomy. He insisted on the importance of separating out such cases from those of splenic anæmia. He thought that the fragility of the red corpuscles was a definite means of distinguishing acholuric jaundice. In true splenic anæmia this was either normal or less than normal.

Sir Bertrand Dawson thought that we should have to recast our present classification of such cases, and had had to modify his views as to the value of fragility. He recounted cases of hæmolytic jaundice without increased fragility. The jaundice was due to over-production of bile pigments, and it was possible that the spleen might be so destructive that it broke up corpuscles of normal fragility. He regarded the manufacture of the precursors of bile pigment as a function of the spleen. Fragility persisted in spite of removal of spleen, and this was so in the case on which Sir Spencer Wells had operated and which was now under his care. In hæmolytic jaundice there were phases of so-called bilious attacks and bile in the urine; he was in the habit of exploring the gall-bladder in such cases, and commonly found either gall-stones or bile mud present, a condition which should be dealt with first. In cases in young people a large spleen was found, but this was not necessarily so, and in older patients hæmolysis probably occurred without splenic enlargement.

Dr. Parkes Weber said that the association with gall-stones had been described by Gilbert, but the proportion of the cases was not a large one. The speaker had suggested the name "spleno-megalic anæmia" for those cases where there were anæmia and hæmolysis but no jaundice. He suspected that the presence of bile pigment in the blood without bile salts might be the cause of the increase of fragility. In obstructive jaundice, where both were present, there was an increased resistance.

Dr. James Galloway showed a case of Banti's disease, which he regarded as a case of splenic anæmia of the Banti type. There had been very severe gastro-intestinal hæmorrhages, and the spleen was considerably enlarged. There was no evidence of syphilis. An ascites had appeared rapidly, which he suggested might be due to portal thrombosis. He invited opinions as to the advisability of removal of the spleen.

Mr. W. D. Spanton said that with the progress of surgery excision of the spleen had become justifiable. In 1866-1875 the mortality was 75 per cent., in 1876-1885 59 per cent., and in 1886-1895 16 per cent.

Other speakers favoured removal of the spleen in Dr. Galloway's case.

Fleet-Surgeon P. W. Bassett-Smith showed a case of kala-azar in an adult from Malta. Every fourth day the man was being treated by intra-muscular injections of atoxyl and of a vaccine prepared from his own cultivated bodies obtained by puncture of the liver. Constant counter-irritation had been applied to the splenic area, and yeast had been given to increase, if possible, the white cells. During the 10 months he had been under treatment, he had not lost ground. No question of splenectomy arose in this case.

Section for the Study of Disease in Children.

Meeting held January 23rd.

The President Dr. Leonard Guthrie, in the Chair.

The following cases and specimens were shown:—

Dr. T. R. Whipham: A case of Kala-azar in a boy, æt. 5. His father contracted Kala-azar in Calcutta a year ago, and died recently from that disease. In March, 1913, when in Calcutta, the boy was taken ill with fever and loss of appetite. The motions at that time were white, but otherwise normal. The abdomen was enlarged when he arrived in England in June, since when he has lost weight and the size of the abdomen has increased. The child is wasted, especially in the limbs and chest; the cervical, axillary, and inguinal glands are enlarged. The abdomen measures 24½ ins. in circumference; the liver extends 3 ins. below the costal margin; the spleen is enormous, extending to the middle line and filling the left iliac fossa. Blood count: Reds, 3,220,000 per cmm.; whites, 2,200; polymorphonuclears, 46 per cent.; lymphocytes, 38 per cent.; large mononuclears, 12 per cent.; transitionals, 4 per cent.; hæmoglobin, 66 per cent. The coagulation time is diminished, being 12 minutes. Leishman-Donovan bodies are present in blood obtained by puncture of the liver. The urine is normal and the motions are now of a proper colour.

Dr. Whipham and Dr. Bassett Smith gave an interesting account of the disease.

Dr. Whipham also showed a case of athetoid movements in a girl, æt. 4½. The movements, which are present in either hand, consist of alternate pronation and supination, which become more marked when objects are grasped. She is the first child of her parents and was born after a difficult labour. The condition is probably due to injury at the time of birth.

Dr. F. Langmead showed a case of malaria in a girl, æt. 3¼. The disease, which commenced in September, 1913, was typical and accompanied by rigors. The mother had malaria while the child was being breast-fed. The spleen extended downwards for four fingers' breadth below the costal margin and the liver was also slightly enlarged. Examination of the blood showed benign tertiary parasites in fair numbers, large intra-corpuscular forms being seen. Under treatment with quinine the spleen has diminished and the patient has improved.

Dr. Eric Pritchard showed a case of abnormal cysts on the shoulders in a baby, æt. 6 weeks. The two cystic swellings were noticed immediately after birth. The presentation is said to have been that of a shoulder (left). The swellings appear to be of the nature of abnormal and persistent capita succedanea.

Dr. J. W. Carr showed a case of (?) Polio-encephalitis. The patient, a boy, æt. 7, had an attack of diarrhœa with severe headache and pains in the limbs in October, 1913. He became unable to stand or speak, and also appeared to be blind. On admission in December, he could not stand alone, and could see only imperfectly, and there was a considerable degree of mental deficiency. The optic discs showed evidence of a subsiding neuritis. After five weeks he began to improve as regards mental condition, sight and movement, though he still has an ataxic gait. Wassermann's reaction negative.

Dr F. G. Crookshank showed a case of Deficiency of Endocrinic Glandular Secretion. The patient, a boy, æt. 32 months, does not speak and is apathetic and flaccid. Some of the features are suggestive of Mongolism. The upper part of the trunk and the arms are relatively less developed than the belly, which is protuberant, and the legs are large and shapeless. The external genitals are poorly developed. It is thought that the child has in addition to some degree of Mongolism, some pituitary deficiency.

Dr. H. D. Rolleston and Mr. E. J. Boyd showed a case of lymphatic Leukæmia under treatment by benzole. A boy, æt. 6½, developed enlargement of the cervical glands after measles and pneumonia. Subsequently the axillary, inguinal, and submaxillary glands also enlarged, and the spleen was palpable. In December, the leucocytes were 60,000; large lymphocytes, 54 per cent.; small, 16.5 per cent., polymorphonuclears, 25 per cent. He was treated with benzole, at first 2 m., and later 3 m., t.d.s. On January 13th, the leucocytes were 16,000; large lymphocytes, 41.5 per cent.; small 46 per cent.; polymorphonuclears, 10 per cent.

Mr. PHILIP TURNER showed a case of a dental cyst following fracture of an incisor tooth, in a boy, æt. 12. The right central incisor was fractured as the result of a fall two years ago. Swelling of the jaw noticed three months ago. There is now bulging forward of the facial aspect of the superior maxilla, depression of the palate on the right side, and widening of the alveolar process. A radiogram showed that the pulp cavity of the fractured tooth was exposed, and that the open apex led directly to the cyst. The right temporary canine had not been shed, and the permanent canine was displaced.

Mr. L. E. C. NORBURY showed a girl, æt. 5½, with deformity of the spine of (?) congenital origin. There was a prominence of the last dorsal and the first lumbar spinous processes. Slight mid-dorsal lateral curvature with convexity to the left. No pain or rigidity. X-ray examination shows a wedge-shaped condition of the first and second lumbar vertebræ. Von Pirquet reaction slightly positive.

Dr. ERIC PRITCHARD showed a specimen of double Hydro-ureter (congenital) in an infant, æt. 7 months, who was admitted for diarrhœa and vomiting. The bladder was not distended but two cystic swellings could be felt internal to the anterior superior iliac spines. The obstruction appears to have been due to valve-like pressure of the dilated ureters, the primary dilatation being probably due to congenital atresia of the ureteral orifices. The renal pelves were greatly enlarged.

Dr. J. PORTER PARKINSON showed specimens from an unusual case of Jaundice, which he considered to have been acute yellow atrophy of prolonged duration. The illness commenced with a rigor. Three weeks later jaundice appeared and the liver was enlarged. The liver was then enlarged but subsequently diminished until death. No leucin or tyrosin was detected in the urine.

Dr. LEONARD GUTHRIE and Dr. G. A. SUTHERLAND made a communication on two cases of Transitory Diabetes Insipidus. The first case was a boy, æt. 2½, in whom the disease lasted about six weeks. He took 12 pints of water a day and the urine, which contained no albumen or sugar, was of specific gravity 1004. There was some diarrhœa, and the motions were of a peculiar bluish-grey colour. In the second case, a boy, æt. 2, the duration was about five weeks. The main symptoms were thirst, drowsiness and polyuria. There was diarrhœa, and the motions were loose, putty-coloured, and offensive. The liver and spleen were enlarged. In each case as the thirst, drowsiness, and polyuria passed off the appetite became voracious for a week or two. A possible explanation is that the intestinal derangement set up toxæmia which, acting on the kidneys, prevented the output of waste products. Another explanation is that the symptoms were due to toxæmic affection of the vaso-motor centres and sympathetic system, or perhaps of the pituitary body.

THE BRITISH OTO-LARYNGOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 29TH, 1914.

Mr. CHICHELE NOURSE in the Chair.

DR. PERCY JAKINS showed the following cases:—(1) A case of cancer of the larynx in a man, æt. 43, with ulceration of both vocal cords; (2) a case of tertiary syphilis of the larynx, with paralysis of the right vocal cord, œdema of the arytenoids, and a positive Wassermann reaction.

The cases were discussed by Mr. C. NOURSE, Mr. C. HEATH, Dr. JACKSON (Plymouth), and Dr. COUBRO POTTER.

Dr. BYRNE replied to the discussion in the absence of Dr. Jakins.

Mr. HEATH read notes of three cases of

AURAL SUPPURATION.

Case 1 (patient shown).—T. J., a boy, æt. 15, had discharge from both ears for eight years following scarlet fever. Years of meatal treatment had proved futile. Eustachian tubes free, and air could be blown through perforations. With the right ear the watch was heard at two inches, with the left only when in contact. Conservative mastoid operation on both sides, enucleation of tonsils and removal of adenoids performed one afternoon. Disease of the antrum found on both sides. Recovery rapid, left the nursing home under a fortnight. Discharge ceased, perforations healed, and hearing increased to 18 inches right, two inches left. Patient went to Australia in a sailing ship. Got a chill "down south," both ears discharged. Right one being painful was re-opened in Australia, but nothing found. On his return to England both ears had healed, but the pain on the right side persisted, due, in the exhibitor's opinion, to inadequate drainage through inner attic route. He therefore re-opened the ear, removed the outer attic wall and the mucous membrane of the roof, thus diminishing the secreting area and the demand for drainage. The ossicles and drum-head being uninjured, hearing was preserved. A few months later pain recurred, and was still regarded as due to inadequate inner attic drainage. Therefore, to insure safety, a radical operation was performed some months later. The mucous membrane of the inner tympanic wall being preserved, the patient can still hear the watch at nine inches. There is no discharge, but the tympanic mucous membrane being moist, fair hearing will probably remain. The ossicles (which were shown) are intact in their bony structures, but the muco-periosteal covering is œdematous, and was partly responsible for obstructing drainage. Mr. Heath pointed out that in early cases such changes in the ossicular periosteum do not occur, and that if the operation had been performed early this ear would have been saved. Prior to the conservative operation upon the other side, the watch was only heard on contact; it is now heard at 18 inches.

Dr. J. COUBRO POTTER expressed the opinion that it was not always advisable in cases of chronic aural suppuration to conserve the drum and ossicles, owing to the liability for fibrous tissue to form in the tympanum after operation, and thus impair the hearing. In regard to closing the Eustachian tube, it is not always a good practice, as after operation hearing is sometimes much improved upon inflation by the use of the Eustachian catheter, after closure of the Eustachian tube the middle-ear is often dry, and a dry ear is often a deaf ear.

Mr. CYRIL HORSFORD also discussed the question of the correct treatment of the Eustachian tube. At the Brighton meeting of the British Medical Association in a discussion on the after treatment of these cases, most members seemed to regard it as a *sine qua non* that the Eustachian tube should be closed. He could not always agree with this. Was it not better to have an ear moist but hearing, rather than dry but deaf? Moisture after operation might be looked on as a sign of success and not failure. Mr. Horsford also thought something might be done in those cases to keep the tympano-meatal cavity moist.

Mr. CHICHELE NOURSE raised the question of the best treatment of the tympanic orifice of the Eustachian tube. It seemed to be an accepted fundamental principle in all cases to curette this orifice. He doubted very much if it was always correct. It would certainly have the effect of drying the tympanic cavity and might seriously impair the hearing.

Dr. LITTLE (Bradford) and Dr. WALKER WOOD also discussed the treatment of the Eustachian tube in mastoid operations.

In reply, Mr. HEATH said that in radical operations he retained the mucosa of the inner tympanic wall and left the Eustachian tube open, because the mucous membrane required a drain, and none was so effective as the tube. To the assertion so often made that with a patent Eustachian tube the tympanic mucosa is liable to infection through it, he would reply that this mucous surface is far more freely exposed to bacterial infection through the large meatus than through the small Eustachian tube, yet it was the latter only which attracted attention. It

appeared to him like straining at a gnat. When possible he preserved the drum-head in order to prevent evaporation from the middle-ear. He would prefer having an ear which is safe and useful even if not quite dry, to one which is quite dry, but deaf.

CASE 2.—Acute otitis media started by tonsillitis with pain in the ear for several days before rupture of the drum-head. There was a tympanic dam of mucous membrane causing extreme deafness by pressing against the drum-head and ossicles. Bone conduction was not increased. Mr. Heath pointed out that the extent of the swelling of mucous membrane was liable to cause obstruction of drainage and acute mastoiditis. Twelve hours later this condition came on, accompanied by severe pain with diminution of discharge. He saw the patient, and removed her to a nursing home for operation. Prior to operation he held a consultation with Dr. William Hill who agreed in the diagnosis of obstruction of antral drainage, *i.e.*, acute mastoiditis. There was no swelling, or tenderness on pressure, behind the ear. Operation: The pent up secretion in the antrum was under great pressure, it was not pus but mucus; the operation had not been delayed long enough for pus to form. Infection streptococcal. The dam of swollen mucous membrane, which was the cause of obstructed drainage, was removed, and shown at the meeting. The antral walls were carious, their lining having been destroyed by the pressure of septic secretion. There was no septic absorption until after this protective membrane had been destroyed. Mr. Heath pointed out that prolonged pain, *i.e.*, pressure, before rupture of the drum-head often causes disease of the antral walls, and that pain persisting after rupture indicates the existence of acute mastoiditis, and the need of a relieving mastoid operation before pus has had time to force its way to the surface or to the brain. Prompt operation in this instance resulted in immediate cessation of pain and fever. This case showed what a great difference there is in the amount of protection afforded to the bone by the lining membrane of different parts of the ear, and demonstrated that the vulnerable part is the weakly defended mastoid antrum.

Mr. HORSFORD would like to ask Mr. Heath from the description of the case what evidence he had to perform a mastoid operation. One often saw cases of pain and temperature after rupture of the drum-head get well. He always performed paracentesis, and gave autogenous vaccines with successful results. He narrated a case in point of pneumococcal infection.

Mr. NOURSE thought it quite legitimate practice in cases of acute otitis media with persistent fever after perforation of the drum should no relief be obtained after free incision of the membrane, to perform a mastoid operation.

In reply, Mr. HEATH said that the persistence of pain and fever after perforation of the drum-head justifies operation. There was far more danger in waiting than in operating. Dangerous dehiscences in the temporal bone may exist and cannot be diagnosed. Patients do occasionally recover without operation in this disease, as in appendicitis, but that does not prove that it is wise to delay and take risky chances. It is a question of danger. Which is greater, waiting or operating? Undoubtedly delay is most dangerous and is at the patient's risk.

Case 3 (patient, Mr. S. J. E., shown).—Discharge from right ear for 23 years, accompanied by deafness, and recently vertigo. Disease started by scarlet fever, Tympanic apparatus destroyed and polypi filling the tympanum. Hearing by air conduction entirely lost; bone conduction diminished. Deafness extreme. Acid-fast squames in the discharge suggested cholesteatoma. Operation: Radical. Cheesy, egg-shaped cholesteatoma found, about an inch in length, probably originating in the antrum, but had increased in all directions and destroyed the bone. Extensive exposure of lateral sinus, and dura mater covering the temporo-sphenoidal and cerebellar lobes, and displacement of contiguous portions of brain. There was a sinus (still visible) leading into the pars petrosa above the external semi-circular canal. Recovery slow but uneventful. Last year the other ear, previously defective, probably from past suppuration, became the seat of otitis media; a few hours' pain before rupture of the drum-head. Next day came to London and was placed in a nursing home. Bed, hot-water bottles applied to ear, salicylate of soda, aperients and autogenous vaccines. Matters went from bad to worse. Tympanic dam formed; deafness and discharge increased. After waiting 12 days a conservative mastoid operation performed. Discharge lessened but did not stop. Inflation, antiseptic irrigation through the attic by way of the now accessible aditus, persevered with for weeks, in the hope of saving this, the only useful ear, was quite ineffective. Disease was already established in the tympanum. It was on account of the rarity of such a condition that the case is considered worthy of record. Four months later a radical operation performed. The mucous membrane of this ear soon dried. Such rapid drying of a mucous membrane undamaged by operation led Mr. Heath to think that it must have undergone serious change before the recent attack of otitis media, and the previously existing deafness lends support to this view. He therefore now considers he was dealing with an ear already considerably altered by disease, and that his chances of saving it by operation or otherwise were not favourable.

Dr. J. COUBRO POTTER referred to the difficulty in diagnosing these various tympanic, attic and other "dams." To him, according to the exhibitor's observations, the treatment in all appeared to be the same.

In reply, Mr. HEATH said that the study of these dams of mucous membrane and their effect upon the drainage of the antrum and tympanum, was most interesting, and when understood, of the greatest help in diagnosis. Sometimes when incising a drum-head for the relief of pressure and pain before spontaneous rupture, the knife after penetrating the tympanic membrane would be found to be penetrating other solid tissues, *viz.*, œdematous mucous membrane, a tympanic dam, such as he had described and illustrated at a former meeting of the Society. In such a case no mucus escapes, because there is none there and no cavity in which it could collect. In a case of this kind which he had treated, only one drop of blood escaped after incision of the drum-head. This was saved and found to contain pneumococci. Though no secretion escaped, the incision gave relief. Next day the pain recurred severely, and when communicated with, he said he would come and operate at 2 o'clock. On arrival the pain had ceased, and the mother asked if operation were still required. Finding that there had been no discharge from the ear, he said operation was still required because the pent-up discharge had not escaped, but had burst into the loose bone below the ear, and though this relieved pressure and pain it still needed to be let out. The subcutaneous tissues behind the ear had meanwhile become œdematous, and removal of the outer table of the skull, half-an-inch from the antrum, gave exit to pus under pressure. This pus, which also contained pneumococci, confirmed the diagnosis of acute mastoiditis. Within two or three hours it had burst through the antral walls and penetrated to the cortex. This patient made a perfect recovery of hearing, and though the infection was pneumococcal, the ear disease was a complication of an attack of scarlet fever.

Mr. CHICHELE NOURSE exhibited a case of double abductor paralysis of very short duration and in which the clinical signs and symptoms pointed to the presence of a mediastinal growth.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

PATHOLOGICAL MEETING HELD FRIDAY, FEBRUARY 6TH, AT THE WEST LONDON HOSPITAL.

The President, DR. F. S. PALMER, in the Chair.

THE following specimens were shown:—

Mr. W. MCADAM ECCLES: (1) Diverticulitis of iliac colon. (2) Empyema of gall-bladder. (3) Two-inch

French nail, swallowed by infant, and passed naturally. (4) Myxo-fibroma of ileum, causing intussusception.

Mr. Souttar: (1) Diverticulitis of ascending colon, with large stercolith. (2) Calcified fibroma of ovary causing obstruction to labour. (3) Strangulated appendix from femoral hernia. (4) Gastric ulcer perforating abdominal wall. (5) Carcinoma of rectum. (6) Fibroids.

Dr. Arthur Saunders: Slides of lymphatic leukæmia.

Mr. Aslett Baldwin: (1) Hydronephrosis. (2) Carcinoma of rectum. (3) Microscopic section of sarcoma of rib. (4) Microscopic section of carcinoma of breast.

Mr. Donald Armour: (1) Two spinal cord tumours. (2) Two brain tumours. (3) Gall-bladder and part of liver removed for carcinoma. (4) Carcinoma of cæcum.

Dr. Ernest Travers: (1) Carcinoma of body of uterus. (2) Microscopic sections of endometrium.

Dr. J. M. Bernstein: (1) Typhoid ulceration of cæcum, colon and appendix. (2) Acute osteomyelitis of humerus. (3) Nasal septum of horse showing glanders.

Mr. N. Bishop Harman: (1) Glioma of the eye. (2) Sarcoma of choroid.

Dr. H. J. Simson: (1) Carcinoma of body of uterus. (2) Fibrosis of uterus. (3) Fibroids. (4) Sloughing fibroid. (5) Extra-uterine gestation.

Dr. R. Elworthy showed a very large number of interesting specimens recently added to the museum.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, February 5th, 1914.

Mr. Adair Dighton read a short paper on

SUBMUCOUS RESECTION OF THE NASAL SEPTUM.

He considered that the operation should not be performed before the 15th to 17th year, nor where there was any evidence of active syphilis. He did not believe in a general anæsthetic, and he emphasised the fact that it was deviation in the upper portion of the septum which was serious.

Dr. Armstrong and Dr. Hay referred to the danger of employing adrenalin when the patient is under chloroform.

Mr. Arthur Evans described the removal of a sequestrum and involucrum from the upper arm of a child. Within six months there was full functional recovery; no bone grafts were needed and no foreign bodies induced.

Mr. Murray referred to the tendency to suppurative pericarditis in cases of osteo-myelitis. He related a case in which he had evacuated the pus from the pericardium, after which the boy recovered.

Mr. Monsarratt gave it as his opinion that as a general rule the diaphysis should not be removed.

Dr. McMurray emphasised the importance of the marrow when bone was implanted

Mr. Simpson spoke and Mr. Evans replied.

Dr. Hubert Armstrong, in a short paper on

SOME CLINICAL MANIFESTATIONS OF CONGENITAL SYPHILIS,

introduced the subject with an expression of opinion that the type of the disease as now seen was decreasing in the severity of the symptoms, but that syphilitic disease of the central nervous system was increasing in frequency. The fulminating case of the infant who practically rotted away despite energetic treatment was becoming a rarity. Recent Wassermann statistics in children were reviewed, and owing to the complication and expense in blood, time and money of this reaction, the need of the perfection of Noguchi's "luetin" cuti-reaction emphasised. On the clinical side, Dr. Armstrong did not regard "marasmus" in which there were no other signs of inherited lues as syphilitic in the true sense, though he thought there were probably cases in which marasmus resulted from the toxic effect of maternal syphilis upon the ovum without actual infection. Such cases would not respond to antisyphilitic treatment. On the question of the part played in the production of congenital deformities by syphilis the opinion was expressed, backed by clinical and Wassermann evidence, that though it was an undoubted factor in a number of cases, it was not so in the majority, which had some other origin. Two rashes—pemphigus neonatorum and eczema seborrhœicum—sometimes mistaken for syphilitic lesions, were described and the diagnosis elucidated. Photographs of a case of "cauliflower" tumour of the anus, a papillomatous mass the size of a large orange, in a boy of nine, and of another patient, a child of eight months, with gangrene of the foot, diagnosed as a combination of Raynaud's disease and congenital syphilis, were thrown on the screen, and a case of paroxysmal hæmoglobinuria in a boy of three related. Other manifestations were touched on, and Dr. Armstrong concluded his paper with a review of the effects of inherited syphilis upon the nervous system. Syphilitic meningitis in children gave a clinical picture resembling that of the posterior basic or meningococcal type. The treatment differing so greatly, lumbar puncture was essential for early diagnosis. Prognosis was fairly good, but blindness, deafness and mental impairment liable to follow permanently. Hemiplegia was often preceded by convulsions and frequently recurrent, the prognosis of functional recovery decreasing after each attack. Illustrative cases were quoted, including one of the fatal termination of untreated cerebral syphilis, death ensuing upon convulsions after the patient, a boy of 11, whose first symptoms dated from a hemiplegia at 7, had gradually become diplegic with extreme spasticity, and imbecile.

The paper was fully discussed by Dr. Hope, Dr. Barendt, Professor Beattie, Dr. Gullen, Dr. Macalister, Mr. Murray, Dr. McKenna, Dr. Warrington, and Dr. Wilson.

Dr. Armstrong replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held in Ruchill Fever Hospital.

The President, Mr. A. Ernest Maylard, in the Chair.

Dr. William C. Gunn discussed

THE PRESENCE OF COMPLEMENT IN INFECTIOUS DISEASES

(full abstract of which will be found on page 170).

Dr. Adam Patrick described

SOME ANOMALOUS FORMS OF THE ENTERIC BACILLUS.

It was found during the investigation of bacilluria in men suffering from enteric fever, that in 6 cases out of 17 the bacilli were not typhoid bacilli, but members of the typhoid-coli group, not previously described. It has always been supposed that the organisms present in typhoid bacilluria are typhoid bacilli, or some contaminating organism, such as B. coli. B. coli did not occur in any of the 17 cases. In seven instances of bacilluria in women with enteric fever, on the other hand, the bacillus present was found in all but one to be B. coli.

These atypical bacilli appeared in the urine on the average after the time for typhoid bacilluria, and persisted for quite a short time—in three instances for one day only. Their appearance was not attended by any constitutional disturbance, and in general the cases resembled ordinary cases of typhoid bacilluria. These bacilli, though practically unaffected by anti-typhoid serum, were agglutinated in varying degrees by the serum of the patient from which each was isolated, in one instance to a greater extent than was the laboratory typhoid bacillus by the same serum. The six bacilli were stored on agar slopes at a temperature of about 6° C., and on re-examination a year later were found to have acquired greater fermentative powers with regard to certain sugars. This property has usually been described as developing by continued growth and sub-culture of an organism in a solution of the sugar, but with these bacilli the power, though afterwards increased by sub-culture, developed in many instances spontaneously.

Dr. W. M. ELLIOTT made a short communication on

THE WASSERMANN REACTION IN CHILDREN FROM THE POORER CLASSES.

His investigation had aimed at ascertaining whether the wasted and unhealthy condition so often found in such children possibly had a syphilitic basis. Of 43 children who were ill-nourished, pale, flabby, and sometimes with sores about the nose or mouth, six gave a positive and two a probable positive reaction, though only three of the eight showed signs of syphilis. Of 45 children who were apparently in good health, three gave a positive and one a probable positive reaction, only one of the four showing signs of syphilis. Of 42 children who were well nourished but had nasal or aural discharge, five gave a positive and one a probable positive reaction, and none showed signs of syphilis. The conclusion drawn was that the proportion of cases in which the impairment of health was due to syphilis was small, but that it was sufficiently large to indicate the desirability of applying the Wassermann test to such children with a view to treatment.

Dr. J. P. KINLOCH discussed "The Excretion of Salt and Nitrogen in the Nephritis of Scarlatina and Diphtheria."

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the fourteenth meeting evidence was given by Sir Arthur Downes, Senior Medical Inspector for poor law purposes of the Local Government Board, and by Dr. E. B. Sherlock, of the Metropolitan Asylums Board.

Sir Arthur Downes stated that the general opinion expressed by poor law medical officers in London was that venereal diseases are less prevalent and milder in type amongst the poor than they were formerly. The opinions of provincial medical officers varied somewhat, but on the whole they appeared to be to the same effect; there were, however, some exceptions, chiefly in seaport towns. His general impression was that the prevalence of venereal disease amongst the very poor was not large.

He explained that under the poor law venereal diseases are dealt with on exactly the same plan as all other diseases, and that it was the duty of poor law authorities to afford relief to all persons in urgent need of any important assistance, such as medical assistance, which they were unable to provide for themselves.

Sir Arthur said that although poor law authorities did not necessarily insist on venereal cases being treated in an institution he believed that a considerable proportion of the authorities objected to affording outside treatment in the case of these diseases. This he thought might have the effect of deterring some people from coming for treatment. The use of the more recent methods of diagnosis and treatment of venereal diseases was confined to a number of the more important poor law authorities. In some of the large unions salvarsan treatment was in use and the Wassermann test was applied. In London a very fine system of poor law infirmaries had been provided, almost all of which were equal in their administration to general hospitals; most of these infirmaries were able to set apart special wards for venereal cases, although they could not always reserve those wards entirely, the number of cases not being sufficient to justify their setting aside beds, which were very valuable. Most of the London Unions sent their Wassermann tests to the Wassermann Institute or the Clinical Research or some pathological laboratory. In the case of the small country unions laboratory provision could not be expected, but the powers of the Guardians to pay for diagnosis and to send patients for treatment in special institutions were very elastic; they had also wide powers of combining amongst themselves for any special purpose.

Referring to the recommendation of the Royal Commission on the Poor Laws that, subject to certain safeguards against abuse, the public assistance authority should have power to detain cases of venereal disease when medically certified to be dangerous to others, Sir Arthur Downes said that he could only support this proposal if the detention was not of a penal character, and was so arranged as to be as little deterrent as possible.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 14th, 1914.

HYDROCELE.

DIVERS are the solutions for the radical cure of hydrocele. The latest is that of formol, glycerine, and alcohol in equal parts as recommended by Dr. Morestin.

The patient is laid on his back and the scrotum painted with iodine at the point of puncture. Neither general nor local anæsthesia is required.

The tumour seized and raised by the left hand, the needle of a hypodermic syringe is inserted for its whole length in its upper part where it should move freely, an indication that it has not wounded the testicle. A little below this point an ordinary trocar is pushed rapidly into the cyst and the liquid evacuated almost completely. The cannula is withdrawn and through the Pravaz needle a drachm of the above solution is injected and the scrotum malaxed to aid in the diffusion of the liquid. No dressing is needed, neither is rest in bed necessary if the patient does not wish it.

Consecutive reaction is not painful, although the scrotum swells considerably for two or three days when regression sets in. At the end of four weeks the parts have returned to their normal condition, but long before this the patient can resume his usual occupations.

CIRRHOSIS OF THE LIVER.

The medical treatment of alcoholic cirrhosis of the liver should tend first of all to diminish the toxines and then stimulate the hepatic function. To meet the first requirement, says Dr. Feissinger, we have only to depend on an appropriate *régime*. Chemical antiseptics are of no use, but lacto-ferments may be employed.

Hepatic stimulants of mineral origin are: bicarbonate of soda at the dose of half a drachm in solution taken half an hour before meals; phosphate of soda at the same doses; benzoate of soda, constantly employed to encourage diuresis and stimulate the hepatic function; sulphate of soda, diuretic and cholagogue. A drachm dissolved in a tumbler of Vichy (Célestins) water is taken each morning, or

Bicarbonate of soda, 1 oz.
Sulphate of soda, 1 oz.

a teaspoonful dissolved in a tumbler of warm water each morning.

Prof. Robin prefers a formula uniting all these elements:—

Bicarbonate of soda, 2 dr.
Phosphate of soda, 1 dr.
Sulphate of soda, 1 dr.
Benzoate of soda, ½ dr.
Iodide of potassium, 15 gr.

for one powder. Dissolve in a quart of boiled water; a wineglass in the morning, another half an hour before each meal and one at night.

Stimulants of the vegetable series are: boldo, an infusion of half a drachm of the leaves sweetened with a teaspoonful of glycerine is taken at bed time; jaborandi, five grains in infusion taken three times a day.

Drastics: podophyllin and compound tincture of jalap. Stimulants of the animal series comprise: glycerine, two tablespoonfuls in an infusion of boldo

taken at night, ox gall, powdered liver, one or two drachms in cachets.

Radium and Cancer.

Dr. Pierre Delbet communicated to the Association Française pour l'Etude du Cancer, the results obtained at the Necker Hospital by radium in the treatment of cancer. The statistics comprised fifty cases diversely localised (skin, parotid, œsophagus, rectum, but chiefly the breast and the uterus). The majority regress for a time, only a few could be considered as cured. Cancer of the os of the uterus was notably improved as regards functional trouble and the general condition. Locally a superficial cicatrix was obtained for a time, but afterwards the cancer continued it evolution, which radium was powerless to arrest; the improvement was only temporary.

The cases reported by M. Delbet dated from two to four years; they were extensive and inoperable.

GERMANY.

Berlin, Feb. 14th, 1914.

At the Berliner Med. Gesellschaft an important discussion took place on the papers of Herren Prof. Bumm and Lazarus. The trend of the discussion cannot be better shown than by a *résumé* of Prof. Bumm's speech on the subject in reply. He said neither time nor experience allowed him to reply to every point raised in the discussion. We were now in the middle of a development of which no one could say what the outcome would be. There were many questions that could be asked in regard to it to which there could be no answer at present. One could only say, "Weiter suchen, weiter probiren," which is freely "Go on seeking, go on testing." There was one question that must be touched on. It was the question nearest to the general practitioner: shall the case be treated by irradiation or by operation? Even this was a question that did not admit of a positive answer. It would be a very easy one to decide if operation did not involve danger and if there were no recurrence after them. The price of the risks of operation would be paid if we could be certain of no recurrences. But what were the facts? Forty to fifty per cent. of recurrences after even the most wide, far-reaching operations. In carcinoma of the uterus the recurrences were about 50 per cent. after radical operation by laparotomy. When the operation was through the vagina the recurrences were 60 to 70 per cent. in young women. The same could be said of mammary carcinoma; recurrence was the rule. The number of cases of radical recovery after operation, however, was still large, and that made the question more difficult to answer. Then there was the danger of operation to be considered. He would mention a case he had had recently—operable carcinoma of the uterus. He had advised irradiation. A consultation inclined more to operation, as it was believed that the glands could also be removed, and after removal of the disease by operation that there was certainty that recurrence could be prevented by irradiation. The patient died from the operation. From the radical operation in cancer of the uterus they had a reduced mortality at one time of 6 per cent.; in the next 100 cases, however, it rose to 15 and even 20 per cent. There were surgical operations that were dangerous, or which involved permanent loss or disturbance of function that made them seriously consider whether irradiation, with its greater risks of recurrence, was not preferable to risky or mutilating operations. It had often been said recently that irradiation was only an old procedure in a new garb, that similar results had been obtained with the thermo-cautery and in many other ways, and they had been given up because no radical cure had been reached by them. Such a comparison could not be made. The effect produced by radium, mesothorium, or Röntgen rays was essentially different from mere mechanical or chemical effects of the knife or cautery. In irradiation there was a direct action on the cancer cells, and if we could do a couple of centimetres deeper what we could already do at the surface we should have done all that could be done by surgical operations. He had recently asked his gynæcological colleagues to examine the uteri they extirpated with the 2 c.m. measure, and see how much that distance exceeded the depth of the diseased portion. Not much further than could now be reached by irradiation. Whoever operated per vaginam could do just as well with the rays. In cases where the operation was likely to be simple and free from danger one would prefer to operate, and especially where the cancer could not be well exposed to the rays. On the other hand, where operation would be followed by loss or disturbance of function the danger would be considerable, and the case was accessible to the rays, it would be best even in operable cases to cure first by the rays. What was lost by doing so? When in a case of carcinoma uteri (he would first restrict himself to the typical case), a carcinoma of the portio, or of the collum, he first healed the surface by mesothorium, or with radium, or with Röntgen; nothing at all was lost by that, even in respect of later operation. On the contrary one would then have to deal with a carcinoma that had been healed that no longer gave off decomposing discharges, so that the danger of infection would have been eliminated. The question, operate, or irradiate, could not at present be answered generally; the decision would follow the circumstances of the case. His meaning was that at the present day it was no longer proper to take one's stand crassly for operation under all circumstances, and only to irradiate in the cases no longer amenable to surgical operations. In this way we should never get any farther forward. It was important to heal the primary carcinoma by the rays, and see whether recurrences were more frequent than after operation. This question had by no means been decided in favour of the rays. Neither was it correct to say that cancer could not be radically cured by rays. He would recommend the perusal of the papers of Wickham and Degrais, where cases enough had been described where cures had been effected—*i.e.*, in so far as a limited lapse of time allowed a judgment to be formed. The *technique* of ten years ago had been quite altered. In those days the rays did not penetrate into the deeper tissues. Any talk of proper irradiation with deep action could only go back a few years.

AUSTRIA.

Vienna, Feb. 14th, 1914.

Heredity and Racial Characteristics in the Crossing of Races.

At the recent Versammlung Deutscher Naturforscher und Aerzte in Vienna, the problem of fertility in racial crossing was discussed by Dr. E. Fischer. He began by examining the data of the fertility of "bastards," as the Burenhottentot half-breeds are specially named, who are the best-known example of intercrossing on a considerable scale. He had himself thoroughly examined those hybrids and their history in South-Western Africa, and had published a monograph dealing with the subject He had found that their numbers remain undiminished, and that they continue fruitful among themselves after many generations. There was, however, no strictly definite proof regarding the crossings of other races. Mulattoes were perhaps somewhat less fertile among themselves, and appeared to have undergone a weakening of constitution; especially in the case of the Mulattoes produced by crossing of the negro with Northern European stocks, while the descendants of Southern European and Negro proved more healthy. Of still far greater interest and importance is the question of the mode and direction of heredity in such inter-racial crossings. Here it can be demonstrated that very many racial characteristics, the inheritance of which has been investigated in the case of plants and of the lower animals by experimental crossing, are transmitted in a similar way; that is to say, in accordance with the so-called Mendelian laws; the parental characteristics of both sides do not, accordingly, appear in mixed form in the grand-children, but "split off," thus leaving

the ancestral features to be reproduced singly in all cases. This fact has been demonstrated with regard to the form of the hair—curled and smooth—and its colour, also with regard to the colour of the eyes and that of the skin respectively, in like manner regarding the form of the nose, by Dr. Fischer himself, in connection with the cross-breeding of Europeans and Hottentots, of the high-arched and flat nose, and by Salaman as regards European and Semitic noses. In the case of many other characteristics, too, is this same course of inheritance in accordance with the Mendelian laws shown to be extremely probable, although not yet demonstratively established as in the case of those just mentioned. Of most special interest is, of course, the question of the inheritance of intellectual qualities in racial cross-breeding. Most of the statements that have been made in this connection have no firm foundation. Exact observation is of extraordinary difficulty. The view which can be maintained with the greatest show of probability is that, in the process of crossing and the development of its products, countless new combinations of the various intellectual qualities of the ancestral stocks really take place. And we can never state positively beforehand whether such new combinations are destined to prove profitable or the reverse in their relations to the progressive culture development of our own and future generations—only after complete mingling of the race concerned has been effected can we carry out carefully, and without the influence of prejudice, an examination of those extremely difficult critical researches and such data are still almost completely wanting. What will be the result of racial mixture? Will new races originate in this way? The most generally received statement at present is that every race impresses its stamp on its products. Presented in this form that statement is false. The fact has been sufficiently demonstrated by experiment in the case of the lower animals, and it can also be stated with regard to man. Certain individual characteristics always break through, whatever be the race in question; of this fact we have example in the dark skin, the curly hair, and the small, turned-up nose. The misconstruing of this phenomenon has led to the view, so widely entertained, that the Semitic type always "breaks through" in the crossing of Christian and Semite, which is inaccurate. The characteristics above named do "predominate"; that is to say, they appear in crosses of the first generation and in 75 per cent. of the following; while the other characteristics do not disappear. New races can result from crossing only through selection and rejection and other auxiliary processes; but never by the process of bastardisation as such. By such segregation and continuous reproduction of individual characteristics is the selective process possible by which the components of a race can again be separated from the general population after racial crossing has taken place—a process to which Luschan gave the name of "Unmingling." Finally, we must "investigate" the direct influence of environment on the racially mixed populations. We know that Boas has recently pointed out that the children born in America of South Italian and East-European-Jewish parents have a form of head somewhat differing from that of their parents. So that we can admit direct influence on racial characteristics—by agencies individually unknown and unexplained. But they do not reach so deep as to obliterate the same so far as to render them indistinguishable. The changeability, however, naturally increases the difficulties encountered in the investigation of the result of the crossing of races; inasmuch as when a resulting population proves to resemble its ancestry, such a collective effect may be due to the altered influence of its environment. But the special observations made in case of actual "bastards," such as those carried out by Dr. Fischer himself in South-Western Africa, demonstrate the fact, with absolutely unquestionable confirmation of Mendel's law of heredity, that the characteristics and differences are actually inherited as definite racial distinctions. Thus the proof is furnished, so far as is necessary, of the fact that the differences of colour of eyes, hair, and skin, which exist throughout Europe are racial distinctions; so are the differences in shape of nose, between Northern Europeans and Semites; and so, likewise, the differences of nose and hair between Europeans and Hottentots.

HUNGARY.

Budapest, Feb. 14th, 1914.

LOCAL ANÆSTHESIA AS A SUBSTITUTE FOR NARCOSIS IN GENERAL SURGERY.

AT the recent meeting of the Budapest Royal Medical Society Prof. Dr. Julius Dollinger said that in his clinic experiments with local anæsthesia were carried out since April 1st, 1913, with the purpose to investigate, that taking in view the present stage of local anæsthesia, how far general anæsthesia can be dispensed with. Since that time they had performed 761 such greater operations, in which formerly general narcosis was necessary. Out of the 761 cases general narcosis was induced only in 31 cases, while the rest (730 operations) have been operated party with local anæsthesia, with injecting around the area of operation, partly with injecting into the nerve stems leading to the respective area. The drug which proved to give best results in his clinic is novocain, in a solution of ½ to 2 per cent. There were cases in which 600 c.c. have been injected from the ½ per cent. solution without any harm to the patient. A *conditio sine qua non* of the success is that the operator shall wait 15 to 20 minutes before commencing the operation. Then the anæsthesia is perfect.

As regards the operations performed in local anæsthesia, he mentioned the following: 11 trephining, 1 suppuration of the antrum mastoideum, 2 Denkel operations, 5 resections of the lower jaw, 4 resections of the tongue, 9 tumours in the ocular cavity, 31 struma, 20 lymphomata colli, 3 tracheotomies, 1 suture of the trachea, 8 resections of ribs partly on account of gangrene of the lung, partly on account of abscesses of the liver, which latter have been opened through the diaphragm. Out of the latter, in one case general narcosis had to be resorted to. Out of 16 operations for breast cancer general narcosis had to be resorted to only in one case. As for abdominal operations, 16 extirpations of gall-bladder (on account of stone) have been performed under local anæsthesia, 2 pancreatic cyst cases, 9 gastro-enterostomies, 6 pylorus resections, 3 enteroanastomoses, 4 colostomies, 1 extirpation of the spleen, 18 exploratory laparotomies, 52 appendicites. General narcosis became necessary mostly in cases of abdominal operations. Out of 142 abdominal operations local anæsthesia had to be replaced by general narcosis in 19 cases only, the rest having been completed without general anæsthesia. When extirpating the gall-bladder, he injects novocain solution between the liver and gall-bladder too; in resecting the stomach he injects the solution into the minor curvature in the proximity of the cardia. Dr. Dollinger operated 160 hernias under local anæsthesia, and out of these only one single case in general narcosis. Anal operations were performed in 22 instances, among them one stricture in general narcosis, nephropexies 2, pyelotomies, nephrectomies 5, high bladder incisions 3, castrations 6, resection of the testes 3, hydrocele 11, varicocele 8, and Pearce Gould amputations of the penis 2, were operated under local anæsthesia. The last operation included also the extirpation of the glands. Out of the operations of the upper limbs, in one instance one whole limb has been removed together with the scapula; there were 7 chronic luxations of the humerus replaced by bloody operations, 6 elbow sprains, 4 elbow resections, 6 fresh but badly-healed fractures were sutured, 2 amputations on the upper limbs, 5 nerve sutures, and on the lower limbs 3 chronic and one congenital luxations of the femur were replaced by bloody operations, two amputations on the thigh, 12 badly-healed fractures and pseudo-arthrites, 8 arthrectomies, and two talus extirpations.

On the upper limbs mostly the Kuhlenkampf anæsthetising method was employed, while on the lower limbs the Reppler method (injecting the nerve stem) has been made use of. Injecting around the area to be operated upon has been administered in two

instances of Macewen osteotomy, and 8 other operations on the bones. Out of the 77 great operations performed on the limbs general narcosis has had to be made in five cases only.

As to the preparation of the patients for the operation, this is done as well as in the cases of a general narcosis. The patient gets ½ gram veronal on the evening previous to the operation, the same quantity on the morrow of operation, and one hour before the operation he gets 1 to 2 centigrams (¼ grain) morphia subcutaneously. Some of the patients show signs of general malaise after the operation. However, this, as a rule, does not last longer than one or two days. Novocain poisoning occurred in one instance only, in the form of a syncope, which, however, entirely disappeared after the lapse of one hour.

UNITED STATES OF AMERICA.

New York, Feb. 7th, 1913.

RADIUM AND CANCER.

DURING the past few weeks the lay press of the country has taken up the question of radium in the treatment of malignant growths. In every part of the United States newspapers have heralded radium as a cure for cancer. That part of the Press known as yellow has, of course, published the most sensational and exaggerated statements regarding the curative properties of radium when applied to cancerous growths. Such journals have out-Heroded Herod, but, as said before, the entire Press of the country has, with surprising unanimity, and with daily and voluminous reiteration, suddenly discovered in radium the specific for cancer. The remarkable popular demonstration in support of radium may be traced, in the first instance, to certain statements regarding radium in the treatment of cancer reported to have been made by Dr. Howard A. Kelly, the well-known surgeon of Baltimore, and who is acknowledged to be an authority on the subject. He is also known to be enthusiastic concerning the value of radium as a means of checking the spread of malignant growths and of occasionally causing these to disappear wholly, and has undoubtedly expressed most optimistic views with respect to the future of radium treatment. These expressions of opinion have been seized upon by newspaper writers, and have afforded the opportunity for highly coloured, not to say lurid articles. Dr. Kelly has been subjected to severe criticism on the part of many members of the medical profession for having given an opening to the lay press to publish far and wide misleading statements as to the curative properties of radium. It has been aptly pointed out that our knowledge of radium in this direction stands almost where it has stood for some considerable time, and yet the newspapers are leading the public to believe that recently discoveries have been made which place radium on a pedestal as a curative agent. Dr. W. L. Wallace, Surgeon to the Crouse-Irving Hospital, Syracuse, N.Y., writing in the *Bulletin* of that Institution for January, draws attention to the fact that no longer ago than November 13th, 1913, at the Clinical Congress of Surgeans of North America, Dr. Kelly claimed to have saved three patients in forty suffering from cancer of the cervix by the use of radium after extensive operations (MEDICAL PRESS, December 24th, 1913), a result which certainly does not justify exaggerated claims for radium. At the same Congress, Prof. Krönig, of Frieburg, as reported in the MEDICAL PRESS, December 24th, stated that by means of radiotherapy they had not succeeded in curing a single case of metastatic carcinoma. In fact, the majority of those who have made a special study of cancer here agree with the views of Drs. Wickham and Degrais given in a paper read before the International Congress held in London during last summer. The gist of these was that operation is advocated in all operable cases, followed by application of radium if a recurrence is to be feared. In those cases in which the growth is difficult of operation radium treatment is advocated both before and after the operation. The authors further admitted that radium had only a local and palliative effect, but that in certain cases of cancer a state of apparent cure had remained for several years. The consensus of opinion of members of the medical profession in America appears to be that in existing circumstances the popular propaganda in favour of treating cancer by radium undertaken by the lay press is peculiarly premature and inopportune. As readers of the MEDICAL PRESS are aware, many of the leaders of the medical and surgical profession in America have been instrumental in inaugurating an educational campaign against cancer by the agency of the Press and of magazines. The object of this campaign is to teach the public how to recognise some of the early symptoms of cancer, so that an individual with such symptoms may consult a medical man, and if his or her fears are realised that operation may be done ere it is too late. The news, however, which has been spread broadcast that radium will cure cancer, will undoubtedly deter many sufferers from undergoing operation, and thus lives will be lost which might have been saved, and much pain, misery and expense will be entailed which might have been avoided. In addition, a large number of cancer patients will fall victims to quacks, who will not be slow to avail themselves of the opportunity given to them by the wholesale advertising of radium as a cure.

THE COST OF RADIUM.

It is possible, however, that some good may come from the newspaper publicity of the professed curative effects of radium on malignant growths. The cost of radium bromide is almost prohibitive, and furthermore it cannot be obtained in sufficient quantities to afford a fair and proper test of its curative or remedial properties. Dr. Kelly has been quoted as saying that if he had a sufficient quantity of radium he could prove that the assertions as to its curative action on malignant growths were true. He may be correct in this statement, and, in any event, enough is known of the beneficial effects of radium to make it highly desirable that radium should be produced in quantities enough to obtain from it its therapeutic effects in the highest degree possible, and to be able to treat all cases of cancer with it which lend themselves to such treatment. There is a distinct feeling in this country that the commercial spirit is too much in evidence as regards the production of radium, and consequently with respect to its cost. The feeling has found expression in a public demand that the United States Government control the output of radium. Secretary Lane of the Interior Department has proposed that all radium-bearing lands be withdrawn from public entry, and that the radio-active ore from these lands be extracted for use in the hospitals of the country in the treatment of cancer. Dr. Kelly, Dr. Robert Abbe, of New York, Dr. C. F. Burnam, of Baltimore, and Dr. Harvey H. Gaylord, of Buffalo, appeared on Jan. 19th before a committee of Congress to urge the Government to act promptly to prevent radium-bearing ores in the public lands from falling into the hands of private individuals, who might monopolise them and prevent radium from reaching hospitals except at exorbitant prices. Dr. Abbe, who is probably the first authority in the country on X-ray and radium treatment of cancer, told the Committee that radium was now selling at inflated prices, but that it would, so far as he could judge, remain high for years to come. The chief source of radium in America is said to be carnotite, an ocherous pigment found mainly and in great abundance in Colorado and Utah, and it is the public lands in these States in which carnotite is found that the Government is being urged to set aside for the extraction of radium for the benefit of suffering humanity. Of course, private interests are fiercely opposed to any such policy on the part of the Government, but it appears that in this instance, at any rate, the public weal will be placed above selfish commercial interests. In reference to the cost of radium, the fact must be borne in mind that other influences may tend to render radium less costly. It seems now that recent modifications of the X-rays, notably those of Coolidge, may bring these rays into active competition with radium in the treatment of malignant growths. In one way, then, it is well that the sub-

ject is being so thoroughly ventilated. At the same time, the publication of erroneous or misleading statements as to the effects of radium by the public Press is to be deprecated. It is neither in the best interests of the community at large nor of the medical profession. In such matters it is better to be too conservative than too radical, and to err on the side of caution.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

MIDWIVES IN SCOTLAND.

ONE of the sessions of the Scottish Nursing Conference held in Glasgow last week was devoted to a discussion on midwifery nursing. Dr. A. K. Chalmers, Medical Officer of Health for Glasgow, read a paper on "The Need for a Midwives Act for Scotland." The present conference, he said, was a good opportunity of having the matter considered dispassionately. It was the almost inevitable result of the work undertaken by local authorities in connection with infant mortality, and the question naturally arose as to the kind of person into whose hands the mothers were to come. England had the advantage of compulsory registration, while in Scotland there was not even a register to which they could refer to ascertain the people who undertook this work. The recent legislation making notification of births compulsory had been of great administrative value, and had enabled them to arrive at certain facts. In Glasgow less than half the confinements were attended by medical men, and more than half by midwives. As regards puerperal fever, it was 3 per 1,000 of the cases attended by doctors and 5 to 7 per 1,000 of the others. Probably more than half the midwives practising in Glasgow were untrained, and it was a curious result of the increased payments possible under the maternity benefit sections of the Insurance Act that a number of old women had re-entered practice as midwives. In any case, whether as a result of the Insurance Act or not, during the last twelve months the number of labours attended by medical men had increased. A letter was read from Dr. J. W. Ballantyne, Edinburgh, supporting the view that there should be a Midwives Act for Scotland. Provision should be made for obtaining medical aid in abnormal cases, and for the payment of medical men called on by local authorities. Miss Paterson, one of the Scottish Insurance Commissioners, stated that it was the opinion of the Commissioners that Scotland should have a Midwives Act. It was admitted by the English Central Board of Midwives that the women trained in Scotland were second to none on the register. It was not fair that these women should have to face the competition of untrained nurses. When the matter was discussed no difference was made in the public mind between trained and untrained midwives. A resolution in favour of an Act was passed unanimously.

GENERAL BOARD OF LUNACY.

Dr. Carsewell, Glasgow, has been appointed a Medical Commissioner in Lunacy for Scotland. Under the Mental Deficiency Act, Miss Kate Fraser, M.D., Ch.B., D.P.H., at present Medical Officer to the Govan School Board, and Mr. James Sturrock, M.D., Medical Superintendent of the Criminal Lunatic Department, Perth, have been appointed Deputy Commissioners of the General Board of Lunacy.

GLASGOW ROYAL INFIRMARY.

From the annual report just issued of this hospital it appears that, notwithstanding the Insurance Act, the contributions by employees in public works show an increase; nor is there, on the other hand, any falling off on the part of annual subscribers, as in the case of some hospitals, but on the contrary an increase, though not a great one, in the annual subscriptions. Although the ordinary revenue showed a deficiency of £25,121 as against the ordinary expenditure, the extraordinary revenue was sufficient not only to extinguish this, but to enable the directors to transfer £16,239 to the reconstruction fund and still carry £14,446 to capital account. There was a daily average number of 656.8 patients treated in the wards, and a daily resident staff of 277. The University Court having arranged with the managers to institute lectureships at the Infirmary for classes which should be open to women as well as men students on diseases of the throat and nose, of the ear and of the skin, have appointed to these lectureships Dr. John Macintyre, Dr. J. Kerr Love and Dr. Alex. Morton respectively, who are the heads of these departments at the Infirmary.

SCOTTISH NURSING EXHIBITION.

This exhibition was opened on 7th inst. with an address by Professor Glaister, who, in the course of it, said that it appeared to him that the time would soon arrive when municipalities in the van of sanitary progress as Glasgow was would consider it a part of the educative measures of their propaganda to establish permanent exhibitions of the chief objects pertaining to the prevention of disease and the advancement of the public health. At the conclusion of his address, Professor Glaister discussed the charge made against preventive sanitary and philanthropic societies that their operations were running counter to the laws of nature respecting the survival of the unfit.

RADIUM FOR GLASGOW.

At the annual meeting of the Ladies' Auxiliary Association of Glasgow Royal Samaritan Hospital for Women this subject was introduced by Dr. Nigel Stark. The question, however, has been under consideration for some time in the city. A movement was initiated by a number of medical men and leading citizens interested in hospital work. A committee of this body has been formed to go into the question and will meet in a few days when it is expected that arrangements will be made for the purchase of a supply of radium which will be available for use in hospitals and in private cases.

GLASGOW LOCAL MEDICAL COMMITTEE.

A meeting of the medical practitioners on the panel in the Glasgow area has been held in the Christian Institute, at which the annual report of the Medical Committee was discussed and adopted. The Committee afterwards met and unanimously elected Dr. A. T. Campbell chairman and Dr. James R. Drever secretary.

BELFAST.

BELFAST MEDICAL GUILD.

THE Council of the Belfast Medical Guild invited the members of the medical profession of Belfast to a supper, which was held on the 11th inst. A large number attended, close on a hundred availing themselves of the Council's invitation. The chair was occupied by the President, Mr. Fullerton. The President, after the toast of "The King" had been honoured, referred to the work the Guild had done in the two years it had been in existence. Much time had been spent by the members in connection with medico-legal questions arising out of recent legislation, and numerous meetings of the Council and committees had been held. It was thought by some of the members that the present year might with advantage be devoted to the more pleasant and social side of professional life. With this end in view a club-room had been taken in one of the most central restaurants in the city, the "Carlton," where members could meet their friends and where refreshments might be had at a reduced figure. Arrangements had also been made for cards, chess, draughts, etc. It was hoped in this way to bring the members of the profession together in a social way and to develop and increase the spirit of brotherliness among them. The Chairman referred to the arduous work of the general practitioner and the need for more time to be spent in recreation. He hoped this move would help rather than hinder the progress of our oldest medical siciety, the Ulster Medical Society, which had been housed in such palatial premises by the public spirit and generosity of Sir Wm. Whitla. He believed that the scientific aspect of the professional

work of the Belfast medical practitioner would also be stimulated by intercourse of a social kind. A large and varied programme of music and recitation was then proceeded with. It is to be hoped that the rather solemn duties of the medical men in this district will, as in other districts, be a little leavened by other such evenings.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

MEDICAL INCOMES AND THE NATIONAL INSURANCE ACT.

To the Editor of The Medical Press and Circular.

Sir,—I thank you for the opening paragraph in this week's Medical Press and Circular, but I think you might have rubbed it in a little more vigorously so far as G.P.s' emoluments from insurance were concerned. The comparatively large average of £230 looks fairly big on being stated as an average, but how very few medical men have received anything like this amount. The returns published in the *B.M.J.* show a much less total. A few men who live in industrial areas, and who did not consider their pledge binding, have received thousands each for the year, but the vast majority of men who joined the panel at or after January 15th have not received more than £100 each, and many men lost as much or more from clubs which were automatically taken out of their hands by the Insurance Act than they gained, and for the clubs they had not to keep records and sign weekly certificates and do any amount of clerical work. The advantage from the Act, of course, is that doctors have not to find medicines.

In my own case, for over 500 insured persons I have received for the year £132. Formerly doctors had not to treat as club patients people earning over £3 a week, nor the sons of well-to-do people who have to enter an office to learn the A B C of stockbroking, banking, or merchandise. The lawyer, as you clearly infer, would not be such a fool as to engage to give advice to the industrial class—to attend to wills, defend in police courts, arrange matrimonial differences, etc., for 1s. 9d. a quarter for each one who might select him, and would certainly not form a consultative body to advise on difficult cases without further charge. So far on this subject I think all G.P.'s would go with you. But then comes the fly in the ointment. Your further paragraphs show that it is not the G.P. but the hospital doctors for whom you have a soft corner in your heart. Why should G.P.'s be paid and hospital staffs exploited? you ask, and in the leading article you elaborate the subject, particularly referring to special hospitals, and ask, "Why should consultants on the staffs of the hospitals be asked to give their services free to insured persons?" The answer is contained in a further paragraph of your leading article: "If deprived of their hospital appointments, as some of them assuredly will be by the inexorable competition of the Insurance Act, the professional career of the ejected will in not a few cases be brought to a disastrous termination." Hospital staffs cannot have it both ways—superiority over panel doctors and a high career as consultants by virtue of appointment, and also enter into competition with G.P.'s. What is the history of most special hospitals. Were they originated for the advantage of the public or for the benefit of the would-be consultants, or to aid poor ignorant general practitioners who know not the difference between lichen and scabies, nor aortic disease and aneurysm, or any of the other specialisms that students are supposed to know before getting a qualification? Although I am not favourably disposed to the Insurance Act for the reason I gave you some time ago that it enslaves the profession, yet if it have the effect as you indicate of closing some of the special hospitals, I think it is "a consummation devoutly to be wished for." Specialism without special knowledge has been the curse of the medical profession for the past twenty years.

I am, Sir, yours truly,

An Old Radical.

London, S.W.
February 14th, 1914.

[Our correspondent apparently endorses the view that all medical services under the Insurance Act, except those rendered by men on honorary hospital staffs, should be paid for under the Act. The majority of cases in special hospitals come because they are sent by general practitioners or because they cannot get special treatment from panel doctors. Surely our correspondent does not claim that the G.P. is master of all the specialities; if not—his argument falls to the ground.—Ed. M.P. and C.]

HOSPITALS FOR THE STUDY OF DISEASE IN DOMESTIC ANIMALS.

To the Editor of The Medical Press and Circular.

Sir,—I have read with great interest Dr. Ernest Glynn's articles in your issues of the 4th and 11th February, and I hope they may lead to something being done in the direction so ably indicated. The matter well deserves the encouragement of the Government; we can look back with satisfaction to the support given by the State at the instigation of Mr. Joseph Chamberlain to the foundation of the London School of Tropical Medicine, which has rendered such good service to mankind.

On one point I would say a word of warning. John Hunter's aphorism, "Do not think, try," may be applied in certain cases as follows: Do not let us think that a micro-organism is ultra-microscopic in all its phases until we have tried well—that is, searched well by aid of the miscroscope—to ascertain whether it does not also assume other phases in which it is readily visible. This caution applies especially to such protozoa as assume the chromidial condition in certain phases of their life cycle.

I am, Sir, yours truly,

J. Jackson Clarke.

Portland Place, W.
February 13th, 1914.

THE NEED FOR SPECIAL COMBINED DEPARTMENTS FOR VENEREAL DISEASES IN GENERAL HOSPITALS.

To the Editor of The Medical Press and Circular.

Sir,—The news that the London Hospital is, through the generosity of the Grocers' Company, about to establish a "Salvarsan Ward" for the in-patient treatment of cases of syphilis will be received with satisfaction, not only by syphilologists, but also by all interested in the eradication of a disease which is more dire in its results than tuberculosis. The old prejudice against the admission of an immoral disease—the relics of a pharisaical exclusiveness—must now go by the board, and syphilitics, even in the active stage, in spite of all the purists' objections, must now receive in-patient accommodation upon equal terms with consumptives. The fear of contagion need not preclude the spread of such a movement, for it is as easy, surely, to secure prophylactic disinfection against syphilis as it is against typhoid fever.

Why should not special departments for venereal disease be established, say, as offshoots of existing skin departments at all the large general hospitals? The two diseases are treated side by side at the principal Continental clinics, as everyone who has visited them knows, and as the manifestations of early syphilis are so *essentially cutaneous*, it seems a waste of energy to place cases of syphilis in a department by themselves.

Let us take the bull by the horns now and organise such departments as soon as possible. Some of the smaller special hospitals have been treating skin and venereal diseases for many years past, thus combining economy in administration with the natural grouping of disease.

To my mind the greatest argument in favour of such

an amalgamation lies in the fact that syphilitics would not mind attending a skin department, whereas they would shrink from the publicity involved in attending a department reserved especially for venereal diseases.

I am, Sir, yours truly,

G. NORMAN MEACHEN, M.D.,
(European Editor, *The Urologic and Cutaneous Gazette*).

[The subject is referred to in our editorial columns. —ED. M.P. and C.]

REVIEWS OF BOOKS.

LECTURES ON MEDICINE TO NURSES. (*a*)

WHEN a book reaches its sixth edition no detailed criticism is necessary, because the popularity of the work has been well demonstrated. We are not surprised at this in the present case, for Dr. Cuff has acquired the art of treating his subject in a very practical manner. No doubt the long connection of the author with the fever service at the North Eastern Fever Hospital accounts for the able way in which the infectious diseases are discussed. We do not think the book is quite suitable for the junior nurse who is just commencing her studies, but for others it should prove invaluable, and it should be of special service to all as a work of reference in medicine. In our opinion the continued success of the book is assured.

LITERARY NOTES.

WE have received from the publishers, Messrs. Baillière, Tindall and Cox, a special public health number of the *Veterinary News*, dated February 7th, 1914. It contains an abundant supply of editorial matter dealing with many of the important ways in which veterinary medicine is concerned with the public health. We may take this opportunity of congratulating the editor upon the improvements that have recently characterised the above-mentioned journal. The type is good and clear, and while there is an abundance of signed original communications, it does not fall into the grievous blunder of proffering an excess of editorial matter for the notice of readers. Certain modern medical journals of our acquaintance appear to consider it essential to their credit and renown to put in type each week the contents of a small volume squeezed within the bursting covers of what was formerly a modest, readable weekly. The *Veterinary News*, although it has now attained the respectable age of "No. 527, Vol. XI.," still retains the slim vigour of a reasonable and prosperous adolescence.

MEDICAL NEWS IN BRIEF.

The Non-Panel Movement in Liverpool.

THE Liverpool Non-Panel Union issued a manifesto last week urging that insured persons should have absolute and unrestricted freedom of choice of doctor, as they had before the Insurance Act came into force. It is proposed to call an early public meeting to further this policy. The manifesto states that it is estimated that between 300 and 400 Liverpool doctors have stedfastly declined to have anything to do with the Act, and that there are about 10,000 non-panel doctors in the kingdom, who have formed the National Medical Union for the purpose of striving to preserve the freedom of their profession and encouraging the public to maintain the liberty of the subject.

(*a*) "Lectures on Medicine to Nurses." By Herbert E. Cuff, M.D., F.R.C.S., Medical Officer for General Purposes to the Metropolitan Asylum Board. Sixth edition. London: J and A. Churchill. 1913.

The Hospital Saturday Fund.

AT the annual dinner of the Hospital Saturday Fund at the Holborn Restaurant on Saturday evening last, Sir Thomas Vezey Strong, who presided, said that in 1911, when the fund reached its high-water mark, the total receipts were nearly £46,000, which enabled some 63,000 benefits to be conferred. In 1913 the receipts had fallen between £4,000 and £5,000. Since the Insurance Act came into force the London hospitals had reported a decrease in the out-patient departments. It was therefore not surprising that there was more and more difficulty in obtaining contributions from the workers. Another difficulty was the number of strikes.

Sir Reginald Dyke Acland said he thought that as time went on the hospitals would find that they had a new sphere of work open to them, and that in the future they would act more as consultants to those who had obtained the services of panel doctors in the first instance. There would be some scheme of medical relief by which trivial and everyday ailments would be dealt with by the panel doctor, and those who require more serious and more skilful treatment would be passed on to the hospitals.

The Liverpool School of Tropical Medicine.

THE Secretary of the Liverpool School of Tropical Medicine has received a letter from the Board of Trade expressing cordial thanks for the part taken by the School in the organisation of the Tropical Diseases exhibit at the recent Ghent Exhibition, and especially thanking Professor J. W. W. Stephens, who represented the School on the Committee of Organisation, and Professor R. Newstead, who collaborated with him in the preparation of the exhibit relating to malaria and other disease. The letter concludes:—"The success which has attended the organisation of this exhibit, the first of its kind to be contributed by this country to an international exhibition abroad, justifies the Board in hoping that it may be found possible to demonstrate even more fully on a future occasion the activities of British medical institutions in the field of tropical medicine. They trust that when such occasion arises they may be permitted to appeal once more to the Liverpool School of Tropical Medicine for the assistance which has been so readily given in the case of the Ghent Exhibition."

Proposed Medical School for Wales.

THE Chancellor of the Exchequer on the 12th inst. received at the Treasury a deputation with regard to the Medical School for Wales. The deputation, which was introduced by Mr. David Davies, M.P., consisted of Lord Kenyon, Lord Merthyr, Colonel E. M. Bruce Vaughan, Sir Almroth Wright, Dr. Ewan Maclean, and Professor D Hepburn. Lord Merthyr was able to announce that the whole of the money, approximately £90,000, necessary to erect and equip the new building, had already been promised. Of this amount Sir W. J. Thomas had promised £30,000, and the donor of the balance wished to remain anonymous. The deputation urged the claims of the Committee of the Institution for a Treasury grant for its maintenance, and it is understood that the Chancellor of the Exchequer, on behalf of the Government, promised that very careful and sympathetic consideration would be given to their request.

Poison by Mistake.

AN inquest was held last week at the West Heath Isolation Hospital, Birmingham, on the body of a canvasser named William Kendal, who died from consumption, but who had had a dose of wrong medicine inadvertently administered to him by a nurse.

Nurse Ethel Freer said she gave the dose from the poison cupboard without looking at the label, feeling sure as to the exact spot in which she had placed the bottles. What she gave the patient was an inhalation mixture containing creosote and carbolic acid, instead of a cough mixture.

Medical evidence was to the effect that the deceased was in such an advanced stage of consumption that his life could probably not have been prolonged many hours, but that his death was accelerated by the mistake.

The Coroner said such an error ought to be impossible in a public institution, and he thought the authorities should make some pronouncement as to their intentions concerning the nurse.

The Medical Officer said she had resigned.

The jury found death was slightly accelerated by the administration of a dose of wrong medicine, and expressed the view that bottles of different shapes and colours should be used to distinguish the physic.

University of Oxford.

IN a Congregation held on February 14th, the following degree was conferred:—D.M., F. O. Stohr, Trinity.

University of Cambridge.

AT a Congregation held on February 13th the following degrees were conferred:—

M.D.—F. W. W. Griffin, King's; J. P. Hill, Caius.

M.C.—S. H. Rouquette, King's.

M.B. and B.C.—W. D. Ross, King's; W. B. Gourlay, Trinity; J. W. Tonks, Caius; H. A. Douglas, Selwyn

B.C.—R. W. Ironside, Pembroke; J. P. Hill, Caius.

Royal College of Surgeons of England.

THE following have been admitted Members of the College:—

A. D. Anderson, University; E. B. Argles, St. Mary's; H. A. Ash, Cambridge and London Hospital; G. Aspinall-Stivala, St. Bartholomew's; C. H. B. Avarne, London; E. R. Bailey, L.D.S.Eng., Guy's; A. C. Ballance, B.A., Oxford and St. Thomas's; F. D. Bana, Bombay University and London; F. M. Barnes, St. Thomas's; W. C. P. Barrett, University; M. H. Barton, University; F. P. Bennett, St. Mary's; A. H. F. Bizarro, Lisbon University and University; P. R. Boswell, B.A., Cambridge and Guy's; A. Bouchage, M.D., Paris University; F. C. S. Broome, Guy's; D. A. Carmichael, Kingston University and London; H. Chand, Lahore and Charing Cross; S. F. Chellappah, Ceylon and London; T. L. Chiplonkar, Bombay and Middlesex; E. L. Christoffelsz, Ceylon and London; W. H. Cornelius, L.D.S.Eng., Middlesex; F. H. L. Cunningham, St. Bartholomew's; J. C. Davies, B.A., Oxford and St. Thomas's; L. R. G. de Glanville, Liverpool and London; R. M. de Mowbray, St. Thomas's; C. K. G. Dick, St. Mary's K. J. Dikshit, Bombay and London; R. H. Dix, Durham; P. Dvorkovitz, St. Bartholomew's; G. D. East, B.A., Cambridge and St. Bartholomew's; M. E. Bakry, St. Thomas's; R. Errington, Durham University; A. P. Ford, London; A. N. Garrod, B.A., Cambridge and St. Bartholomew's; N. Gray, Cambridge and St. Bartholomew's; F. H. Guppy, St. Bartholomew's; H. Gwynne-Jones, London; W. R. H. Heddy, Middlesex; D. A. Henderson, Toronto University and Middlesex; C. L. Herklots, B.A., Oxford and University College; E. S. W. Hirsch, St. Mary's; G. A. Hodgson, Leeds; T. J. H. Hoskin, B.A., Cambridge and Middlesex; N. S. Jatar, Bombay and University College; D. W. Jones, Guy's; G. L. Jones, Cardiff and Middlesex; T. A. Jones, B.A., Cambridge and London; M. M. Khan, Bombay and London; J. G. L'Etang, St. Bartholomew's; G. H. S. Letchworth, B.A., Cambridge and St. Bartholmew's; R. J. McN. Love, London; N. P. L. Lumb, St. Thomas's; R. G. Lyster, St. Bartholomew's; K. H. McMillan, St. Thomas's; D. G. McRae, London; J. E. Margant, M.D., Paris University and St. Mary's; F. D. Marsh, B.A., Cambridge and St. Bartholomew's; E. H. Marshall, King's and St. Thomas's; W. H. Marshall, B.A., Cambridge and St. Thomas's; J. H. Mather, Liverpool; R. K. Merson, Cambridge and London; G. C. Metcalfe, Cambridge and University College; L. E. Napier, St. Bartholomew's; H. G. Oliver, Cambridge and London; W. J. Parramore, University College; C. F. Pedley, Cambridge and Guy's; R. A. Preston, London; J. L. Priston, London; G. B. Pritchard, L.D.S.Eng., Guy's; W. R. Pryn, Guy's; J. H. Rawson, St. Thomas's; S. A. Riddett, L.D.S.Eng., Leeds and Middlesex; G. D. Robertson, St. Mary's; P. H. C. C. Schmidt, Freiburg University; A. G. Shera, B.A., Cambridge and University College; C. Sherris, Guy's; R. Silcock, St. Mary's; F. G. A. Smyth, St. Bartholomew's; T. R. Snelling, London; A. H. Southam, B. A., Oxford and Manchester; M. T. W. Steedman, B.A., Cambridge and St. Bartholomew's; C. K. Sylvester, St. Bartholomew's; J. B. Thackeray, London; M. C. Thavara, Guy's; F. Tooth, Sydney University and Guy's; H. Topham, Leeds and London; T. R. Trounce, L.D.S. Eng., Guy's; D. S. Twigg, Sheffield; J. B. Vaidya, Bombay and University College; R. E. S. Waddington, St. Bartholomew's; G. H. D. Webb, University College; F. E. Weerasooria, Ceylon and University College; J. R. White, New Zealand University; S. B. White, B.A., Oxford and Westminster; L. C. Wilkinson, St. Bartholomew's; J. F. W. Wyer, B.A., Cambridge and St. Bartholomew's.

Royal College of Surgeons in Ireland.

THE Charter Day Dinner of the Royal College of Surgeons of Ireland was held last Wednesday, the President and Fellows being honoured by the presence of His Excellency the Lord Lieutenant. A large company was present and a very pleasant evening was spent. Among those who spoke were His Excellency the Earl of Aberdeen, Mr. R. D. Purefoy (President), Mr. F. C. Dwyer (Vice-President), Sir Charles Cameron, Dr. James Little, the Master of the Rolls, and the Rev. J. P. Mahaffy, Vice-Provost of Trinity College. On behalf of the Council of the College, His Excellency presented the President with a silver tray in recognition of his eminent services to the College. At the same time a handsome pendant was presented to Miss Purefoy. Messrs. C. W. Wilson, Melfort D'Alton, John Horan and Morgan contributed an excellent musical programme.

DR. W. T. GRENFELL, C.M.G., will lecture on "My Life in Labrador" at the Queen's Hall on Monday next. This will be his first public lecture in London for the purpose of raising money for his work in Labrador, and the American Ambassador will preside.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

PERSIMMON.—The term "albumen" is now confined to describe the chief constituent of the white of egg; "albumin" to this constituent when found to exist elsewhere, such as in the albuminous bodies, inclusive of all substances having a general resemblance to albumen.

DR. T. W. (S. Wales).—The hypnotic action of *Humulus lupulus* is very feeble, but, nevertheless hop pillows are credited with inducing restful sleep in certain types of insomnia.

ROYAL WARRANT FOR MESSRS. A. WULFING AND CO.

The medical profession has long been acquainted with the products of Messrs. A. Wulfing and Co. Awards of merit have been bestowed on the firm at various professional congresses and exhibitions held in various cities in Europe. The King of Spain has recently given his Royal Warrant to Messrs. Wulfing for Sanatogen, Albulactin and their other products. The bestowal of this warrant gains additional interest from the fact that, as we are informed by Messrs. Wulfing, albulactin is used in the Royal Nursery for their Majesties' infants.

EX-HOUSE SURGEON.—It is usual to make a personal visit of introduction upon all the medical men residing in the immediate neighbourhood.

DR. PEARCE.—We will make inquiries, and let our correspondent know privately by post.

SHIP'S SURGEON: R.M.S.P. AND P.S.N.C.

We are asked to state that under the revised arrangements which have just been concluded, the rate of remuneration of Ship's Surgeons on the Companies' South American Mail Steamers has been fixed at £12 10s. per month; on the R.M.S.P. West Indian, Canadian and "D" Class Steamers to South America, the pay is now £14 10s. per month. In addition to this pay they are allowed to charge fees for professional attendance on passengers as under:—5s. per visit to 1st Class, and 2s. 6d. for 2nd Class Passengers. Surgeons on the Companies' Steamers have a private cabin and a surgery set aside for their use, and there is also a hospital fitted with every modern convenience. Hospital attendants are carried on the Mail boats, and doctors on the R.M.S.P. Mail Steamers are in addition allowed a personal servant. The many advantges of life on board are too numerous to mention here, and they should not need any recapitulation to members of the medical profession, but it may be pointed out that a voyage on the Steamers of either Company presents additional attractions in the shape of the many interesting ports of call on the routes. On the South American run the ships call at ports situated in no less than 6 different countries, and also at such well-known beauty spots as Madeira and Las Palmas. The West Indian route, although perhaps not quite so cosmopoliton in its character, is every bit as interesting, and also moreover affords an opportunity of visiting the Panama Canal.

Application for appointments on the R.M.S.P. Steamers should be made to the Company at 18, Moorgate Street, London, E.C., and on the Pacific Line boats to the Pacific Steam Navigation Co., 31 James Street, Liverpool.

MR. A. HOPE (Leeds).—There are numerous artificial foods now upon the market which contain protein of a vegetable nature, though the better known ones contain those derived from milk. A glance through our advertisement columns will show the merits of some of these excellent preparations.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 18TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lectures:—Prof. A. Keith: Evolution and Diseases of the Anthropoid Apes: Lecture I., Living Forms of Anthropoids: Their Distribution and Chief Characters; Lecture II., The Growth and Form of Brain in Anthropoid Apes; Lecture III., A Comparison of the Periods of Development, Growth, and Life amongst the Various Forms of Apes. (Illustrated by specimens from the Museum of the College; the epidiascope will also be used.)

THURSDAY, FEBRUARY 19TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Dr. H. G. Adamson, Dr. Freeman, Dr. Nixon, Dr. Pernet, Dr. Norman Meachen, Dr. J. M. H. McLeod, Dr. Russell Wilkinson, Dr. Knowsley Sibley, and Dr. Corbett. 8.30 p.m.: Special Meeting: Debate on Pityriasis Rosea (to be opened by Dr. Graham Little).

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Mr. E. W. Scripture (New York): Speech Defects of Children and their Treatment.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Dockrell: Seborrhœa and Psoriasis dealt with as Stages of the Same Dermatitis in Symptoms, Diagnosis, and Treatment.

FRIDAY, FEBRUARY 20TH

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases and Specimens by Dr. Dundas Grant, Dr. W. H. Kelson, Mr. C. Ernest West, Mr. Richard Lake, Mr. G. J. Jenkins, and Mr. W. M. Mollison.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Paper—Fleet-Surgeon P. W. Bassett-Smith, C.B., M.R.C.P. and S., R.N.: Recent Researches Relating to Undulant or Mediterranean Fever. (Specimens illustrating Barton's Bodies and the Other Blood Changes in Oroya Fever will be shown.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lectures:—Prof. A. Keith: Evolution and Diseases of the Anthropoid Apes: Lecture I., Living Forms of Anthropoids: Their Distribution and Chief Characters; Lecture II., The Growth and Form of Brain in Anthropoid Apes; Lecture III., A Comparison of the Periods of Development, Growth, and Life amongst the Various Forms of Apes. (Illustrated by specimens from the Museum of the College; the epidiascope will also be used.)

MONDAY, FEBRUARY 23RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF ODONTOLOGY) (1 Wimpole Street, W.).—8 p.m.: Mr. F. St. J. Steadman: Oral Sepsis as a Predisposing Cause of Cancer.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Clinical and Pathological Meeting.

TUESDAY, FEBRUARY 24TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE) (1 Wimpole Street, W.).—5.30 p.m.: Dr. R. Hutchinson and Dr. John Parkinson: Case of Paroxysmal Tachycardia in a Child of 2¾ Years. Dr. Gordon R. Ward: Secondary or Symptomatic Leucæmia, with Special Reference to Cancer with Bone Metastases.

Appointments.

CARSWELL, JOHN, L.R.C.P.Edin., L.F.P.S.Glasg., a Medical Commissioner in Lunacy for Scotland.

FULLER, H. WARDLAW, L.D.S.Eng., Dental Surgeon to the Poplar Schools at Shenfield, Essex.

LITTLE, FRANCIS ERNEST, L.R.C.P.Lond., M.R.C.S., Honorary Consulting Surgeon to the Teignmouth (Devon) Hospital.

NORRIS, A. H., M.R.C.S., L.R.C.P.Lond., D.P.H., by the Home Secretary a Medical Inspector of Reformatory and Industrial Schools.

PALMER, F. W. MORTON, M.D., B.C.Cantab., Honorary Medical Officer to the Teignmouth (Devon) Hospital.

ROBB, A. LAWRENCE, M.B., Ch.B.Aberd., Assistant School Medical Officer to the County Council of East Sussex.

TITTERTON, JOHN TARRATT, M.B., C.M.Edin., Medical Officer of Health of Saltash (Cornwall).

WILKINSON, KENNETH D., M.D., Ch.B.Birm., Pathologist to the Birmingham and Midland Freed Hospital for Sick Children.

Vacancies.

Manchester Royal Infirmary and Dispensary.—Appointment of two Honorary Assistant Physicians, two Honorary Assistant Surgeons, and an Honorary Dental Surgeon. Applications to Walter C. Carnt, General Superintendent and Secretary. (See advert.)

Cardiff City Mental Hospital, Whitchurch, near Cardiff.—Second Assistant Medical Officer. Salary £250 per annum, all found. Applications to the Medical Superintendent.

Free Eye Hospital, Southampton.—House Surgeon. Salary £100 a year, with board, lodging, and laundry. Applications to Edward C. Redman, Secretary.

Dewsbury and District General Infirmary.—House Surgeon. Salary £120 per annum, with board, residence, and washing. Applications to Edward Hemmingway, Secretry, Infirmary, Dewsbury.

Devon County Asylum.—Assistant Medical Officer. Salary £220 per annum, with furnished quarters, board, and laundry. Applications to the Medical Superintendent of the Asylum, Exminster.

St. Bartholomew's Hospital, Rochester.—Resident House Physicial. Salary £110 per annum, with board, residence, and laundry. Applications to Charles Speyer Secretary.

Preston Royal Infirmary.—House Physician. Salary £100 per annum, with board, residence and laundry. Applications to Mr. Walter Davies, Secretary, 5 Winckley Street, Preston.

Births.

DONALD.—On February 12th, at Liskeard, Cornwall, the wife of John Donald, M.D., of a daughter.

MELVILLE.—On February 14th, at Muir House, Tidworth, the wife of Colonel C. H. Melville, Royal Army Medical Corps, of a son.

ROPER.—On February 14th, at Exeter, the wife of Dr. F. A. Roper, of a son.

TATTERSALL.—On February 13th, at Beachy, Neath, South Wales, the wife of Dr. Norman Tattersall, of a son.

Marriages.

FRANKAU—MCDOUGALL.—On February 11th, at All Saints Parish Church, Milford-on-Sea, Claude Frankau, F.R.C.S., of 63 Wimpole Street, W., younger son of F. J. Frankau, of Hampstead, to Edith Lorne, third daughter of the late A. F. McDougall, of Rendham, and Mrs. McDougall, of Milford-on-Sea.

SECRETAN—CROSSE.—On February 10th, at St. Giles' Church, Reading, Walter Bernard Secretan, M.B., F.R.C.S., eldest son of Walter Secretan, of Croydon, to Dorothy Crosse, younger daughter of the late Rev. Edward Ilbert Crosse.

Deaths.

BARTLETT.—On February 12th, at 14 Woodfield-road, Ealing, Lydia Sarah, beloved wife of Edward Bartlett, M.R.C.S., L.D.S., of 38 Connaught Square.

COLGATE.—On February 14th, at The Seven Gables, Eastbourne, Ethel Dobell Colgate, wife of Henry Colgate, M.D., F.R.C.S., aged 55.

FARRANT.—On February 10th, at Sierra Leone, Captain Percy Farrant, R.A.M.C., aged 32.

GILCHRIST.—On February 8th, at Cimiez, Nice, Dr. A. W. Gilchrist, aged 58.

KNOX.—On February 8th, suddenly, at Church House, Bakewell, Derbyshire, John Knox, M.D., aged 69.

MAXWELL.—On February 13th, at 29 Woolwich Common, Woolwich, Theodore Maxwell, M.D., B.A., B.Sc., aged 66.

PAUL.—On February 14th, at "Costebelle," Torquay, John Ernest Paul, M.D., son of the late Deputy-Surgeon General John Liston Paul.

SKINNER.—On February 12th, at 124 Devonshire Street, Sheffield, Edward Skinner, L.R.C.P.Edin., M.R.C.S.Eng., aged 66.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, FEBRUARY 25, 1914. No. 8.

NOTES AND COMMENTS.

A Tuberculous Panel Patient.

THE sanatorium benefits have come into operation with the blessing of the medical profession, and with the approval of all parties in Parliament. It is somewhat disconcerting under such circumstances to find sanatorium benefit dragged into the field of politics. In the election contest last week at Poplar the constituency was circularised by a non-governmental candidate with the history of a clerk, aged 22, who last November applied for sanatorium benefit. He died on February 14th, and all that time "all the Insurance Committee offered him was six quarts of milk and some cod liver oil." On the strength of this statement the voters were asked to note how the Government had deceived the people, and to vote in favour of drastic amendments and improvements of the Act. This treatment of the subject is disingenuous, a survival of Eatanswill tactics hardly creditable to a great London constituency. A cold official account, moreover, places the clerk's relations to the Insurance Act in a very different light. His application reached the committee on December 8th, when the panel doctor recommended medicine and cod liver oil, and, in reply to a specific question, advised home treatment for the patient. Milk was allowed on December 13th, and the doctor told to state his requirements and to say if the milk was sufficient. On January 24th the patient's father applied, and the matter was referred to the panel doctor. The specific question was asked of the latter on February 7th as to whether he advised treatment other than domiciliary; the answer on February 12th was that the patient was too far gone, and, as a matter of fact, he died two days later. The case evidently was not fitted for sanatorium treatment from the first. Anyway, if there be any blame attached to anyone it does not lie with the administration of the National Insurance Act. It seems unfair that an attempt should be made to make political capital out of the unhappy death of a victim of tuberculosis by attacking the only practical organisation ever yet devised by Society for the succour of those in like distress.

Political Contests and Sanatoria.

WHATEVER be the defect of the National Insurance Act from the medical point of view, there is one thing in which its value is conspicuously apparent, namely, the treatment of tuberculosis. Until Mr. Lloyd George appeared on the scene—a modern Juppiter armed with thunders that have not yet ceased to reverberate—there was no national organisation for dealing with what Fleet Street loves to describe as the "great white scourge." The voluntary consumption hospitals did their best, but failed to do more than touch the fringe of the problem. For the rest there was nothing but a little haphazard relief from various charitable and Poor-law sources. Now all that has been changed. An attempt has been made to supply residence in a sanatorium for all consumptives whose condition demands institutional treatment. It can hardly be expected that an organisation on so vast and costly a scale would spring into existence within twelve months. As a matter of fact, it seems likely that two or three years must yet elapse before the accommodation will meet the demand. During the year 1913 no less a sum than £891,000 has been spent on sanatorium benefit. That amount has been expended by the State in the treatment of deadly disease which previously had been left practically without skilled medical attention. That great step in advance is due to the National Insurance Act, a particular point upon which all medical men, no matter what their opinions upon the Act generally, must agree. From the outset of this legislation, indeed, medical men have had nothing but approval of the sanatorium benefits. Then, again, it is to be assumed that the above-mentioned sum of £891,000 does not include domiciliary treatment of consumption.

A New Children's Charter.

THE past week in Parliament has witnessed the second reading of a non-party Children's Bill. Thirteen years is now the absolute minimum age for leaving school; that anomalous compromise, the "half-timer," is abolished; street-trading is not allowed for boys under fifteen or girls under eighteen years of age. The Bill passed the Commons by a big majority, 157 voting in its favour and 35 against it. The minority was represented by Sir Frederick Banbury and a few others on the somewhat forlorn ground that the State should not intervene between parents and children. Curiously enough, they were supported in their opposition to the Bill by Mr. Wedgwood, an advanced Radical, because the poorer classes were already too much dragooned by the State bureaucrats. While he agreed with education and wholesome conditions of environment, and so on for the young, he lodged a strong protest against further compulsion. A majority of 152 against these views, however, illustrated the inevitable trend of modern opinion. After all, the science of public health is based on common-sense laws that are well within the grasp of the man in the street. The central principle embodied in measures for the protection of children is that the health of the young is essential for the succeeding adult generation. If ever the world be blessed with a millenium of universal health (and why

not?), it must be brought about by the education of the people whose representatives crystallise into law the teachings of science with popular assent and approval. The medical profession as a whole will cordially approve a measure which extends the protection of young persons.

Finger Prints.

THE recent death of the famous ethnologist, M. Alphonse Bertillon, recalls the time when his wonderful anthropometric system was first brought before the Paris police. Previous to the year 1882 no systematic measurements of convicted criminals were taken in Paris, and it was not until eleven years later that Bertillon's system was made general in this country, upon the recommendation of a Departmental Committee. Owing to the variable influence of the personal equation, the measurement system, scientific as it was, broke down, and in 1901 a second Departmental Committee recommended that Bertillonage shoud be discarded in favour of the Henry system of identification by finger-prints based upon the work of Francis Galton. The fourfold classification of Henry, now commonly adopted, of whorls, loops, arches and composites, simplifies the study of finger-prints considerably, and the number of identifications now on the register at New Scotland Yard is said to exceed 200,000. So popular has the system become that many private individuals possess autograph registers of their own in which to record the "thumbo-graphs" of their friends. Next we shall see medical diplomas adorned, literally, with the sign-manual of the holder in the shape of his finger-print, instead of, or in addition to, his ordinary signature. The former is a permanent record, whereas the latter may change with advancing years.

LEADING ARTICLES.

A LAWYERS' PANEL.

SOME weeks ago Mr. Lloyd George, in one of his recurrent fits of optimism when dealing with the fortune of other folk, made much of the average income of £230 that had accrued to panel doctors under the Insurance Act. How the lawyers would jump at such a grant! cried he, with a fine display of rhetorical fireworks and sarcasm. It does not do to take a public orator too seriously, especially when his utterances flow in a copious flood comparable to that which is lost in the turbulent sprays of Niagara. We pointed out at the time of the speech, however, that the legal profession, if it contemplated joining a State panel, would have to reproduce more or less the facts, circumstances and conditions attached to the existing medical Insurance system. We sketched a respectful picture of the lawyers founding a complex system of hospitals and dispensaries, where legal advice and assistance of every kind would be provided free to all poor persons, that is to say, roughly, perhaps to about two-thirds of the community. This free legal benefit, be it remembered, would be absolutely the best and most highly skilled and responsible that could be obtained (*vide* the work of the voluntary medical charities). In addition to the privilege of serving on the honorary staffs of legal hospitals lawyers would be permitted to apply for £230 (average) panel posts. It is delightful to picture the feelings of a solicitor called upon to perform the varied and exacting round of multifarious service which the panel doctor has to render at a munificent sum, varying according to local conditions, from some 6s. to a remotely possible 8s. per patient per annum. No more easy office hours for the solicitor; he would have to sit morning and evening at times convenient to the insured. Above all, he would be liable to be called to distant visits and to night work without limit. Private practice would naturally be easy under such circumstances, for legal gentlemen who fortunately are not harried and perplexed by the disconcerting developments of a rapidly progressive science like that of medicine. The moral of our sermon lay obviously in the fact that the medical profession has been saddled with a State service on terms that would be contemptuously dismissed offhand by the lawyers as simply farcical and degrading. But what was written in jest is apparently coming true, partly, at any rate, in sober earnest. Last week it was announced that a number of new rules had been drafted by a committee of the Lord Chancellor with several judges and members of the bar. Their scheme affords legal assistance to litigants who wish to sue *in formâ pauperis*. The irony of that particular method has hitherto been its serious expense. In future an application from the poor petitioner must contain a short statement of his case and the affirmation that he is a poor man. A panel of local legal men willingly to serve will then investigate the case and furnish an "opinion" gratis. No court fee will be chargeable, ad it is actually proposed to raise a fund of £50,000 to pay the petitioners' necessary out-of-pocket expenses, including the cost of witnesses. So far the new rules have applied only to divorce. This suggested revolutionary departure is in various ways one of the most striking evidences of social dissatisfaction which have cropped forth in the present generation. The legal profession does not represent a quarter from which altruism and self-sacrifice are expected. Yet there is no valid reason, so far as can be seen on the surface, why the burden of ministering to the woes and wants of mankind should be specially cast on the shoulders of medical men. So habitually overworked and underpaid is the medical profession that the Chancellor of the Exchequer, in forcing upon them medical service under the Insurance Act, actually boasted that thereby he had doubled the previous rate of pay at three or four shillings per head! Strong politician as he is, we doubt if Mr. Lloyd George would try to saddle the legal profession with a similar panel service. The lawyers are finely organised for defensive purposes and have a whip hand in Parliament. What would happen were the secretary of the Incorporated Law Society offered a lucrative post while negotiations were being carried on for legal insurance legislation? A

lawyer, however, is not likely to commit a tactical error of that sort when dealing with lawyers, however far he might adventure in that direction when dealing with a badly organised profession like that of medicine. If the future is to see a State medical service, there is no obvious reason why a similar principle should not be applied to law, as it has been for many centuries applied to religion.

HOUSING CONDITIONS IN DUBLIN.

In November last, when the Local Government Board appointed a Departmental Committee to inquire into the housing conditions of the working classes in Dublin, we, in common with other organs of public opinion, pointed out that the method chosen was inadequate for its purpose. We are still of that opinion, though we gladly admit that Mr. O'Conor and his colleagues have produced a valuable, and for an official document, a remarkably courageous report. Nevertheless, thoughtful and careful as it is, it cannot carry the weight that a report of a Vice-Regal Commission would have, and it will be exposed to criticism that such a report would have escaped. At the same time it has some points of value, which a report by a more independent body would miss. In its strong condemnation of the public health administration of Dublin, it must be regarded as a judgment, not only of the Dublin Corporation and its sanitary staff, but of the Local Government Board itself. The facts concerning the tenement houses of Dublin must by now be fairly familiar to our readers, and it is not necessary for us to recapitulate them in detail. A little over one-fifth of the population of Dublin—22.9 per cent., to be exact—live in one-room tenements; 78 per cent. of the total number of tenement lettings are of single rooms. More than one-fourth of the tenement houses belong to the class described by the sanitary staff of the Corporation as "Third Class" – that is to say, "houses unfit for human habitation and incapable of being rendered fit for human habitation." This class of house accommodates 22,701 persons. The Committee states that the closets for the tenement houses are nearly always insufficient in number and are kept in a filthy condition. The halls and landings and yards are also in a filthy condition, and not uncommonly strewn with human excreta. It is no wonder that with one-fourth of the population living in such conditions, the death-rate of Dublin is higher than that of any other large city in the kingdom. The Committee considers carefully the powers possessed by the Dublin Corporation for dealing with the tenement question. It was necessary to discuss this in some detail, as apologists for the Corporation have been fond of declaring that its powers were inadequate. It now appears that not only has the Corporation failed to enforce its own bye-laws on the owners of tenement houses, but it has neglected to carry out the duties mandatorily imposed by Parliament with regard to the keeping of a register of tenement houses. In particular, in regard to the provision of closets have the bye-laws been dispensed with. The Committee found that in the case of over a thousand tenement houses, one closet had to serve from twenty to forty or more persons. The bye-laws provide for one closet for every twelve persons. The Committee sum up in one sentence a view often expressed in these columns:—"The plea of the Corporation in regard to the insufficiency of their powers would have considerably more force were it supported by evidence of a rigid administration of existing powers." In regard to this matter, the Committee brings a very serious specific charge. Under the Dublin Corporation Act of 1890, there is power to grant a rebate of taxes to the extent of 25 per cent. on premises which are suitable as dwellings for artisans or labourers. The object is obviously to encourage the provision of suitable dwellings. It appears that, as a matter of fact, rebates have been given on houses classed by the sanitary staff as "third class" under the definition given above, and the rebate has been on the authority of the Superintendent Medical Officer of Health! In several instances these rebates have been given to members of the Corporation, who own property of this kind—"incapable of being rendered fit for human habitation." It cannot be said that the majority of the Committee puts too heavy a condemnation on the sanitary administration in stating "that it would seem that the want of a firm administration has created a number of owners with but little sense of their responsibility as landlords, and that it has helped much in the demoralisation of a number of the working classes, and increased the number of inefficient workers in the city." The recommendations of the Committee are far-reaching. The third-class tenements must be swept clean away. Instead of these it is suggested that a sufficiency of self-contained cottages to accommodate every working-class family should be provided. The Committee arrives at the conclusion that some 14,000 cottages will be required, which would cost some three and a half million sterling. Sensible suggestions are made for the encouragement of private enterprise, as, for instance, considerable extension of the present powers of giving rebate of taxation. It would be reasonable, for instance, to give a full rebate of taxation for a period of, say, ten years, half rebate for another ten years, and 25 per cent. thereafter. It is, of course, assumed that the conditions governing a rebate would in future be rigidly observed. After, however, allowing full scope for private enterprise, a problem still remains for the community. A careful analysis of figures shows that under the present powers of the Corporation such an expenditure would place on the rates an additional charge of 1s. 5½d., if the rent charged were such as the tenants could reasonably pay. This charge is certainly greater than the city could bear, and there is, we believe, a good case for direct aid from the State. The problem will require grave consideration and thought, to which this report will give much help. If the labour dispute which dislocated the trade of Dublin for several months past has so far done little good to either party to the quarrel, it has, at any rate, roused the public conscience to the fact that a large proportion of Dublin workmen live under conditions in which decency and self-respect are all but impossible. The working-classes of Dublin must be given a chance.

CURRENT TOPICS.

Advice on Sanatorium Building.

FOR the adequate treatment of consumption by the open-air method it is not essential that palatial edifices should be erected. A high degree of comfort can well be attained by simply constructed buildings which must, of course, fulfil their primary function as hospitals for the sick, and afterwards as residential hotels. The Local Government Board has recently issued to county councils and county borough councils a circular, prepared by the architect and the Medical Officer to the Department—Mr. Brook Kitchin and Dr. Newsholme—containing advice as to the economical provision of new permanent residential institutions for the treatment of pulmonary tuberculosis. The unit taken in setting out details is 100 beds in buildings, with 10 additional beds in shelters. It is suggested that the site of a sanatorium should be sufficiently large to permit of the employment of a considerable number of patients in the open air, and that it is desirable that a site of 50 acres should be provided for 100 patients if land is readily available and the cost is low. Not less than 20 acres, however, may suffice for that number of patients where suitable land is dear or difficult to obtain. In all cases at least one-fifth of an acre for each patient should be allowed. Some hints are also given as to the planning of institutions according to the stage of disease of the patients to be admitted. The accommodation, it is urged, should be so arranged that a floor space of at least 64 square feet will be available for each patient. Patients' rooms should be not less than 8 ft. 6in. high, and the wards should be higher. In view of the importance of the continuous open-air treatment of patients, it is suggested that it is unwise to encourage them to collect in a recreation room, except for a very limited time or on special occasions, and therefore any other common room, except one for meals, may be regarded as almost superfluous. The authors of the memorandum say that it will usually be unnecessary to heat the patients' quarters, except the dining hall and some of the rooms for patients requiring special nursing, and that a system of low-pressure hot-water heating will be found most economical. Electric lighting may be employed where the electric current is available or can be produced economically.

The Modern Eskimo.

PEARY, in his book, "The North Pole," describes a curious form of neurosis which affects the Greenland Eskimo. It is called "piblokto." During an attack "the patient, usually a woman, begins to scream and tear off and destroy her clothing. If on a ship she will walk up and down the deck, screaming and gesticulating, and generally in a state of nudity, though the thermometer may be in the minus forties." The performance usually ends by the lady dashing about on the ice like a leaf-less Eve, till forcibly rescued by her calmer friends. An anthropologist with the expedition was sure that there was some loss of consciousness in all cases subsequent to the attack. The Eskimos attribute the disease to an evil spirit. The Freudians, on the other hand, would see in it some form of sex manifestation. Love makes the world go round, and its psycho-analytic extensions do the same for the human head. As piblokto is almost exclusively a feminine attribute, we may assume its purely sexual character. A psychic trauma produces in the childlike Eskimo a comparatively simple outburst instead of the complex manifestation that would be preferred by a more highly civilised woman under similar conditions. In these conditions simple savagery has its advantages. The Eskimo who behaves in the manner described is only liable to hurt herself. It seems essential to our neurotics—who have a truer social instinct—to make themselves a nuisance to all with whom they come into contact.

Braces and the Well-Being of the Lungs.

IT will be generally admitted that every condition which interferes with physiological breathing diminishes the standard of health and *pro tanto* creates an increased liability to pulmonary tuberculosis, whether the interference comes from breathing impure air or from mechanical hindrance to the proper movements of the chest in inspiration. It is contended in some quarters that wearing braces or suspenders to maintain the trousers in position constitutes such a hindrance. They are usually drawn tightly over the shoulders and cannot do otherwise than hamper the expansion of the thorax in inspiration. Possibly this may, in part, explain the physiological observation that, in men, inspiration is chiefly diaphragmatic in contrast with the inspiratory act in women in whom it is chiefly thoracic. It is not as though the use of braces were indispensable to the maintenance of the nether garment in position. On the Continent, at any rate, their use is the exception among the working classes, who trust to a belt to obviate any risk of sudden denudation, and the respiratory freedom thus obtained is indisputably an advantage. Not until corpulence obliterates the natural waist does it become necessary to sling the trousers over the shoulders. The reality of the mechanical hindrance is shown by the fact that braces never form part of the equipment of the athlete—cyclist, tennis player, boxer or what not. Trousers cut to be suspended over the hips do not necessitate an inconvenient degree of constriction, at any rate, in the well-built subject still possessed of a waist, so that braces might well be regarded as one of the drawbacks incidental to advancing years, possibly indispensable but assuredly undesirable. The wearing of braces, however, has been and is practically universal among the males of races that affect trousers, while pulmonary phthisis is happily undergoing a notable decrease. Moreover, the general mortality does not differ between the brace-wearing and non-brace-wearing sexes as would happen were the ill effects of the suggested chest constriction by the brace a reality.

Fashion in Surgery.

ONE would think that a really scientific procedure, based, as it should be, on ultimate and undeniable truth, would be quite independent of the vagrant variations of the moment's modes. Surgery, above all the other branches of clinical medicine, claims to be scientific, but we find its ablest exponents wavering like weathercocks in the corporeal trimmings they recommend from time to time. There is a sort of tendency to do some particular operation when there is no special indication for doing anything else. It used to be gastro-enterostomy. For a few years every skilled surgical sempster spent his mornings short-circuiting somebody's intestinal tract. Then he grew tired of stitching, and lately he began to undo the things he ought not to have done, and let the patient's aliment revert to the *cursus quo ante*. Then tonsils had a turn. They were amputated, snared, cauterised, and shelled out like peas. We looked upon a non-tonsilliferous people, and saw that it might not be good. Remorse took hold of us, and we began to think about tonsils. The

thought struck someone that since we have tonsils in our throats they may have been put there for some purpose. So the tonsil acquired a function. There is little agreement and less evidence as to what the function is, but the human tonsil has certainly had one for the last two or three years. We cannot rehabilitate the once evicted structure, but we can give it a close season, lest the breed become extinct and tonsillectomy a memory. The *Johns Hopkins Hospital Bulletin* gives reasons for leaving tonsils and their attendant adenoids where they are. General sepsis, endocarditis, torticollis, meningitis and such unpleasant complications have been traced to their removal; and other disadvantages are raised. It seems that we must have an operation for doubtful organs. There are still several left. No one has yet treated the sinus pocularis.

The Injurious Effect of Noise.

It is curious to observe the different effects produced by noise upon different individuals. The highly sensitive and nervous person can neither work with his brain nor sleep while any loud, intermittent or discordant sounds are going on. Even the noise of happy children at play floating in through his study window he cannot endure, while the lugubrious strains of the weekly organ-grinder are to him a maddening torture. His more phlegmatic neighbour, on the other hand, whose ear is less musically inclined, remains blissfully unconscious of the piano next door, and were the telephone to ring every minute throughout his waking hours he would scarcely be conscious of anything unusual. There is no doubt that musical people suffer more intensely from the effects of noise, considered as irregularly produced sound-vibrations, than others who are said in common parlance to have "no ear for music." In these days of increased industry and invention we have to pay the penalty for our super-civilisation in the shape of its most important and injurious by-product, noise, as Dr. Clarence Blake, of Boston, has significantly remarked. If otologists are agreed that noise in excess predisposes to deafness—or, at any rate, blunts the finer sensibilities of hearing—then deafness should be on the increase at the present time, in spite of silencers and rubber tyres. A musical contemporary attempts to explain the modern demand for mere noise in orchestral pieces by the fact that our nervous system would be conscious of no thrill in the concert room by listening to the old masters. A scientific investigation into the effect of different noises upon the sense of hearing would be of assistance in determining the injurious influence, or otherwise, of noise. Where deafness is bliss it may be folly to hear.

Air-Borne Diseases.

The belief is still rife that a large number of diseases is conveyed by the breath of infected individuals, and that the germs of such affections are scattered by the four winds of heaven. Friends of patients suffering from influenza or pneumonia are frequently told that they may sit by the bed, provided they do not "take their breath." Nervous people, carrying eucalyptus-laden handkerchiefs, may be seen timidly inquiring at the door of a house wherein such a patient is lying, fearful even to step over the threshold lest they should, perchance, inhale some germ that might have escaped from the sick room. It is hard to kill old beliefs of this kind. Nevertheless, the theory of the aerial convection of certain infectious diseases has held its ground even up to the present time. Careful inquiry, conducted upon the lines of bacteriological research, has resulted in undermining this faith to a considerable degree. Dr. Charles V. Chapin, of Providence, R.I., has contributed to the *Journal of the American Medical Association* a thoughtful article upon the subject, in which he shows that for tuberculosis alone is there any evidence that air-borne infection is a factor of any importance, and even this is not absolutely conclusive. Germs may flourish upon particles of dust, or they may be transmitted from one person to another in the act of sneezing or coughing, but neither in the case of consumptive sanatoria nor fever hospitals can it be said that cross-infection is common. The evidence as to the aerial transmission of measles is conflicting at the present time. It is likely that further researches may yet cause many of our views regarding the aerial spread of disease to be seriously modified.

PERSONAL.

Dr. John Selfe has been appointed Assistant School Medical Officer to the Cheltenham Education Committee.

Dr. J. W. Fraser has been appointed whole time School Medical Officer to the City of Hull Education Committee.

Dr. Sydney J. Cole, M.D., B.Ch. Oxon., has been appointed Medical Superintendent of the Wilts County Asylum, Devizes.

Mr. L. A. Parry, M.D., B.S.Lond., F.R.C.S., has been appointed Assistant Surgeon to the Sussex Eye Hospital, Brighton.

Dr. G. Hely-Hutchinson Almond, M.B., B.Ch. Oxon, has been appointed Assistant Pathologist to the Royal United Hospital, Bath.

Mr. Herbert F. Marshall, F.R.C.S.E., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Macclesfield General Infirmary.

Dr. E. B. Sherlock, M.D.Lond., has been appointed Medical Superintendent of the Dareuth Industrial Colony of the Metropolitan Asylums Board.

Prof. Gustav Killian, of the University of Berlin, will deliver the Semon Lecture for 1914 at the Royal Society of Medicine, 1 Wimpole Street, W., on Thursday, May 28th, at 5 p.m.

Professor Arthur Keith, F.R.S., was awarded the triennial medal of the West London Medico-Chirurgical Society upon the occasion of the annual dinner thereof last week at the Wharncliffe Rooms.

Mr. John W. Bird, M.R.C.S., L.R.C.P., who acted technically as "common informer" in the recent action against Sir Stuart Samuel, M.P., whereby the former was awarded £13,000, is an ex-naval surgeon.

Mr. J. Ireland Bowes, M.R.C.S. Eng., L.S.A., was the recipient of a suitable presentation the other day upon his retirement from the post of Medical Superintendent of the Wilts County Asylum, after a tenure of nearly forty years thereof.

Professor H. R. Kenwood, C.M., M.B., D.P.H., F.R.S.E., has been appointed a Representative of the University of London (also in respect of University College) at the Twenty-ninth Congress of the Royal Sanitary Institute, to be held at Blackpool in July, 1914.

CLINICAL LECTURE

ON

THE USES OF DRIED MILK IN INFANT FEEDING. (a)

By ERIC PRITCHARD, M.A., M.D.Oxon., M.R.C.P.Lond.,

Physician to Queen's Hospital for Children; Physician to Out-patients, City of London Hospital for Diseases of the Chest, Victoria Park, etc.

WHETHER regarded from the economic, commercial or nutritional point of view, milk is such a valuable food that there is little cause for surprise that human ingenuity has been constantly engaged in attempts to discover some practical means of preserving it, and thus preventing the serious losses which naturally occur in so perishable an article of food. But so innumerable and deep-rooted are the prejudices in favour of fresh milk, that inventors and manufacturers have experienced almost insuperable difficulties in obtaining a market for even the best varieties of preserved milk. In spite of the physiological evidence that a limited degree of heat does not impair the nutritive qualities of milk, the public and, I regret to say, a small section of the medical profession still believe that a diet of boiled milk is incompatible with good nutrition. The huge collective experience of Infant Consultations not only in England, but also throughout Europe and the whole of America, has proved beyond question that the sterilisation of milk has had even a greater influence in reducing infant mortality than the most careful attempts to provide an absolutely irreproachable milk supply. In this connection it is particularly interesting to note that the chief pioneers of the "pure milk" movement in America are now the most active agitators for pasteurisation. For reasons which I have elsewhere (b) summarised, it is beyond question true, that a limited degree of heat does not impair the nutritive qualities of milk, although excessive heating or prolonged keeping may destroy certain principles in milk or other fresh foods which are essential for good nutrition. These principles are known as vitamines, but they can be so easily supplied in an independent form, in orange juice or grape juice for instance, that their possible destruction by heat is no argument against the pasteurisation, sterilisation or desiccation of milk if these operations confer other and important advantages.

There are many factors concerned in infant mortality, and of these good and careful mothering is undoubtedly the most important. This condition has been more or less satisfactorily provided wherever infant consultations have been introduced, but some of the best results, of which I have personal knowledge, have been in those consultations in which the teaching of good mothering has been combined with the employment of dried milk. The experiences of Leicester, Sheffield and Marylebone in England, and in many centres in France and Belgium, prove this conclusively; and in this connection I cannot refrain from quoting a passage (translated) from Professor C. Porcher's "Le lait desseché," page 122. (c)

"At a certain infant clinic in Gand (Belgium) the infant mortality rate was 260 per 1,000 in the year 1901. In the year 1903 sterilised milk was supplied to the infants, and the rate fell to 150 per 1,000. In the year 1907 a house-to-house visitation scheme, carried on by trained health workers was inaugurated, and the death rate fell to 60 per 1,000. In the year 1908 dried milk was substituted for sterilised dairy milk, and the rate fell to 34 per 1,000." This striking experience proves that the very best results are not irreconcilable with the use of dried milk. Dried milk, however, without good mothercraft, is of no more avail than breast-milk, dairy milk or any other kind of food under similar conditions.

Before I proceed to a description of the methods of employing dried milk in infant feeding, I may perhaps be permitted to make a few general remarks on the history of its manufacture.

Although attempts were made in the middle of last century to further advance the stage of condensation of milk and completely dry it, all efforts in this direction proved a complete failure until, in the year 1903, Mr. S. Amundsen succeeded in employing on a commercial scale a method of desiccation invented a few years previously by Dr. Ekenberg. Necessity is the father of invention, and the establishment of Mr. Amundsen's factory in Kristinnia was almost the necessary consequence of the fact that in this district of Sweden there was a considerable butter industry, and a large and unavoidable loss of by-products and residuals: the separated milk, although largely used for the fattening of pigs and other animals, proved so perishable and difficult of transport, that it entailed a very considerable waste of valuable material. By the Ekenberg process, which I shall shortly describe, the separated milk was reduced to dryness and distributed among farmers in a highly convenient and transportable form as a food for their animals. This early venture, however, cannot be described as an unqualified success, and chiefly for the reason that the market for desiccated separated milk was at that time extremely limited, and partly because the method could not then be used for the desiccation of milk from which the butter fat had not been extracted. This difficulty in the drying of fat has proved the rock on which many milk-desiccating ventures have come to grief.

It was not long, however, before the Ekenberg process was so far improved that it enabled manufacturers to produce dried milk on a commercial scale without the preliminary removal of the cream, and from that time forward one improvement after another was introduced until at the present moment there are three distinct methods of manufacture, each good in its way, and each possessing special advantages.

The principle of the Ekenberg process consists in the partial condensation of the milk at a low temperature under reduced pressure, and its subsequent desiccation within the interior of cylinders heated to a comparatively low temperature. The milk solidifies into a crystalline mass on the surface of the cylinders which are kept in constant rotation, and this mass is subsequently broken up and pulverised. This method is not employed to any large extent in this country, but it is more popular in France and in other parts of Europe. In England the method usually employed is that which is known as the Just-Hatmaker process. In this method the previously concentrated milk is spread on the outer surface of rotating cylinders which are heated to a high temperature by steam (160° C.). The thin film of milk dries very rapidly on the highly polished surfaces, and when dry is scraped off by sharp knife-blades, and subsequently pulverised as in the Ekenberg process. This is the process which has been made familiar to a large section of the British public by frequent demonstrations at Earl's Court and other exhibitions.

The third process is generally known as the Bévenot-de-Neveu method, the process consists in

(a) A lecture delivered before the Post-Graduate Course of the National Association for the Prevention of Infant Mortality.
(b) "The Milk Problem," Bedrock, January, 1913, page 515.
(c) Asselin et Hougeau, Place de l'Ecole de Medecine, Paris, 1912.

concentrating the milk "in vacuo" and at a low temperature, and then forcing it under high pressure (250 atmospheres) through minute perforations in a metal disc into the drying chamber. The nebula of homogenised milk is then surrounded by an envelope of dry and hot air and swept across the chamber. Owing to the fine state of division of the particles in which the condensed milk is presented, and to its intimate contact with dry air, the milk is almost instantaneously desiccated and falls as an extremely fine powder to the floor of the chamber. The moisture thus evaporated is carried off as a cloud of steam, while the snow-like desiccated milk is rapidly swept up from the floor and packed in tins or other receptacles.

The distinguishing feature of this method lies in the rapidity with which the concentrated and homogenised milk is evaporated in the drying chamber. So finely atomised is the milk that even at comparatively low temperatures the moisture is almost instantaneously evaporated; indeed, this evaporation is so rapid that the water is removed from the coagulable ingredients such as the whey proteids, before they have time to become coagulated by the heat, at least this is the explanation which has been given to account for the possibility of reconstituting with water the coagulable substances which have been desiccated by this method. On any other grounds it seems difficult to explain how it is that substances such as meat juice and chlorophyll can be completely desiccated by the method at temperatures which would, under normal conditions, coagulate and destroy their organic properties, and thus render them insoluble in water.

By the Bévenot-de-Neveu process of desiccation, milk and whey can be reduced to the condition of a very dry powder containing no more than 1 per cent. of water, apparently without losing any of their natural properties, that is to say none of the enzymes or vitamines appear to be destroyed, and the milk when reconstituted with water can be coagulated by rennet or heat, precipitated with acids, and soured by lactic acid ferments just as is the case with milk fresh from the cow. Moreover, when allowed to stand the cream will slowly rise as it does with fresh milk which has been homogenised.

These results are to my mind of immense advantage, for the chief objection usually raised to desiccated milks is that they are so profoundly altered by the heat to which they have been subjected in the course of manufacture that they no longer possess those subtle and vital properties which are supposed to be essential for good nutrition.

Milks desiccated by the three processes which I have briefly described certainly possess very different physical properties. Some of them possess distinctive chemical properties as well, for to certain of them chemical substances such as phosphate of sodium, saccharated lime or glucose are added to facilitate the operations of drying and to render the finished product more readily soluble in water.

The appearance of milk which has been dried on the surface of cylinders as in the Ekenberg or Just-Hatmaker processes, and subsequently scraped off and pulverised, is that of irregular polygonal plaques of varying dimensions and of striated structure, whereas the powder dried by the Bévenot-de-Neveu process is very much finer and more homogeneous.

As regards solubility, the cylinder-dried milk is fairly soluble in hot, but resistant to cold water. The Bévenot-de-Neveu milk is equally soluble in hot and cold water, and can be readily reconstituted by beating with a fork or special whisk.

The appearances of the two kinds of milk, *i.e.*, the cylinder-dried and the air-dried, are also quite distinctive. The colour of Just-Hatmaker milk is biscuit yellow, that of Bévenot-de-Neveu milk of a peculiarly snow-like white, and when allowed to stand the fat rises in the former as a yellow oil, whereas in Bévenot-de-Neveu milk the fat rises in the form of a rich cream. The odour of the cylinder-dried milk is very agreeable, and distinctly biscuity in character. The odour of Bévenot-de-Neveu milk is slightly tallowy, especially when it has been kept for some time. This tallowy smell is due to the oxidation of the fat, a result which appears to follow from the fine state of division in which the fat particles are presented to the oxygen of the air. Although this oxidation in no way affects the nutritive value of the milk, from a commercial point of view it undoubtedly detracts from its popularity. This, to my mind, is a great misfortune, for in all other respects Bévenot-de-Neveu milk is as superior to other varieties of desiccated milk as fresh milk is to stale milk. This taste, however, is one to which most people soon become accustomed, after they have drunk the reconstituted milk for some little time; indeed I have noticed that children who have been brought up on Bévenot-de-Neveu milk seem to dislike the taste of fresh milk. Inasmuch as this suety or tallowy flavour at present interferes with the domestic employment of desiccated milk of this variety, I hope most sincerely that some method of packing with nitrogen or other indifferent gas will be introduced to prevent this regrettable oxidation of the fat.

Dried milks, whether prepared by the cylinder or the air-process, are usually sold in three qualities, firstly, as "full-fat" milk from which no cream has been extracted before drying; secondly, as "half-cream" in which part of the fat has been removed, and thirdly, as desiccated milk from which all the cream has been separated. To these three varieties yet a fourth may be added, namely milk modified to the standard required, or supposed to be required, for infant feeding.

These milks vary in price in proportion to their cream content. Full-cream milk sells at about 1s. 6d. per pound, and separated milk at about 7d. When reconstituted with water and made up to their origina bulk, the best dried milks cost practically the same as the best dairy milks, *i.e.*, about 4d.–5d. a quart.

Had I time and space, I should like very much to enumerate the economic and domestic uses of dried milks, but I will content myself by referring to one point only. Dried milk is, indeed, as Professor Porcher says, "la vache dans le placard," that is to say, if you have dried milk in the house you are as well off as if you kept a cow in the larder ready to be milked at any moment. Dairy milk deteriorates from the moment it is milked up till the moment of consumption; if it is consumed 18 hours after milking the degree of deterioration may be very extreme. Dried milk represents milk which has only deteriorated between the time of milking and the time of desiccation; this usually is not more than four hours, and need not be more than one hour.

Now let me proceed to a description of the uses of dried milk in infant feeding.

In the first place I would very strongly emphasise the fact that dried milk is no better adapted to the physiological requirements of infants than is ordinary cow's milk. That is to say, if infants are to be fed exclusively on desiccated milk the latter must be modified to the nutritional and digestive requirements of the particular infant in the same way that cow's milk must itself be modified.

I am well aware that many medical men are of the opinion that infants can be brought up quite successfully on whole milk which has not been modified in any way, and I am prepared to concede the point that some infants will muddle through without any serious disasters even on diets so little suited to their needs as the unaltered milk of the cow. But I deny altogether that the best results can be obtained in this way.

The physiological requirements of the infant and the calf are quite different, they live under different conditions and grow at different rates.

If there is any truth in the generally held belief that the proportions of proteid, fats and carbohydrates in the milk of different species of mammals is designed to meet the distinctive requirements of their own particular young, it seems to me to be most illogical to expect that the milk of two mammals so widely separated as the human being and the cow can be mutually interchangeable.

It is the simplest thing in the world to teach an infant to digest cow's milk, even in the undiluted or in the non-citrated condition, but because a food is easily digested it does not necessarily follow that the proportions of its main constituents are well adapted to the physiological requirements of the consumer, and if I know anything about the physiology of nutrition, I am prepared to state quite definitely that cow's milk, in its unaltered condition, is not adapted to the physiological needs of the infant. If cow's milk is to be used with success in infant-feeding, it must be modified by dilution and fortified with fat and sugar, or treated in some other way to bring it up to the approximate standard of breast-milk, and if dried milk is to be used for the same purpose, it also must be modified in the same way.

At times I am almost reduced to despair when I observe medical men, who might be expected to have a wider knowledge, employing desiccated milk for the feeding of infants, just as if it were a ready-made and perfectly adapted food, and only required to be dissolved in water.

If a good variety of dried milk is diluted with water in the proportion of one part of the powder to eight parts of water, the resulting mixture is, or should be, of the same percentage composition as the undiluted milk from which it was originally prepared.

If, therefore, undiluted cow's milk can be regarded as a good food for a baby, all that it is necessary to do is to prescribe so many ounces of the reconstituted dried milk made up in the proportion of one drachm of the powder to one ounce of water.

But if you wish to modify the resulting mixture so that it shall approximate to the composition of breast-milk, you must proceed more carefully, dilute more freely and add cream and sugar.

Assuming the percentage composition of breast-milk to be: 1.5 per cent. proteins, 6.5 per cent. carbohydrates, and 3.5 per cent. fat, a mixture of this percentage composition (Formula I) can be prepared by combining two tablespoonfuls of "full-cream" dried milk, six teaspoonfuls of sugar, one ounce of thick cream (46 per cent. fat), in one pint of water. Such a mixture, however, in this noteworthy respect fails to correspond with breast-milk, *i.e.*, it supplies practically the whole of its protein content in the form of caseinogen, and not in the form of caseinogen plus whey-proteins. Some authorities attach very great importance to whey-proteins in infant-feeding, and attribute many of the failures to rear infants successfully on cow's milk, or dried milks, to this defect.

In breast-milk, the total 1.5 per cent. of protein is made up of .5 per cent. caseinogen and 1 per cent. whey-proteins, whereas in cow's milk the proportion is, approximately, 3 per cent. caseinogen to 1 per cent. of whey-proteids, and in ordinary desiccated milks the deficiency of whey-proteids is even more accentuated. If, therefore, dried milk is to be so modified as to correspond to breast-milk in respect of its content in whey-proteids, these whey-proteids must be added independently.

From this point of view, it is extremely fortunate that the Bévenot-de-Neveu process of desiccation permits of the manufacture of a whey powder which, when reconstituted with water, almost exactly reproduces the original whey from which it was prepared. Dried whey powder of this kind is sold under the name of Sweet Whey or Sec-Wa, and, indeed, at a comparatively low price.

Now, by an appropriate combination of dried milk, whey powder, sugar and cream we can prepare a humanised milk which has a percentage composition the same as human milk, namely: Caseinogen 0.5 per cent., whey proteins 1 per cent., sugar 6.5 per cent. fat 3.5 per cent. The formula is as follows (Formula II.):

Full-cream dried milk, 3 teaspoonfuls; Sec-Wa, 2½ tablespoonfuls; sugar, 2 teaspoonfuls; thick cream, 1 oz. (46 per cent.); and water to 1 pint.

This is a very valuable substitute for breast milk, but somewhat expensive to use owing to the large quantity of dried whey powder and cream required in its preparation.

According to the view I hold, this care with respect to the exact balance between the different kinds of proteins, *i.e.*, the caseinogen and whey-proteins, is only necessary in the case of quite young or delicate infants who have not acquired the power of digesting caseinogen.

For strong, healthy infants, who have been accustomed to take ordinary cow's milk, or who have been gradually habituated to larger quantities of caseinogen by a graduated course of feeding, I strongly recommend a mixture of the following formula (Formula III.); Proteins 2.5 per cent. (caseinogen chiefly), sugar 6.5 per cent., fat 3.5 per cent.

This is prepared by combining 1 oz. of "full-cream" dried milk, ½ oz sugar, 1½ ozs. thick cream (46 per cent.), and water to the pint.

The transition from Formula II. to Formula III. should be slowly and carefully conducted by the gradual substitution of the sugar and the full-cream dried milk for the whey-powder.

I feel this account would be incomplete without referring to the use of dried separated milk, although the only advantage in using "separated" milk is one of economy.

I am now feeding a large number of infants on desiccated separated milk and modifying it for use by adding supplementary fat, and also by adding a small quantity of sugar. The best fat to add is cream, but this is expensive, but any other fat or oil will answer the purpose; perhaps a combination of several fats is even better than one single variety of oil, which may not contain the different fatty acids in the required proportions. But I have obtained such excellent results with an emulsion of linseed oil which is generally known as Marylebone cream (*a*), that perhaps it is hardly worth while complicating the issue with such fine considerations and nice distinctions, although at the present time I am experimenting (*b*) with other oil combinations, which contain olein, stearin and palmitin in relatively the same proportions as they exist in butter fat.

The formula for preparing 20 ozs. of a mixture of separated dried milk and Marylebone cream is as follows (Formula IV.):

Separated dried milk, 1½ ozs.
Marylebone cream (50 per cent. fat), 1½ ozs.
Sugar, ½ oz.
Water, to 1 pint.

The cost of feeding infants on such a mixture is extremely low—about 2d. a day.

In all cases in which dried milks or other preserved foods are employed, I believe it to be a safe precaution to give in addition some fresh fruit-juice or other anti-scorbutic. I always make it a practice to order a teaspoonful of orange juice, or the expressed juice of two grapes to be given to all infants [illegible] exclusively on dried milks.

Although I have given a considerable number of formulæ for the preparation of various milk mixtures made from desiccated milk products, any person who slavishly follows these formulæ will assuredly fail to achieve the best results. The whole art of scientific feeding consists in the adaptation of the food to the individual requirements of the infant. The individual requirements of the infant can only be understood by a long study of the infant both in health and disease, and by a full appreciation of the caloric values of food elements, and the expenditure of heat and energy in the growing child. These matters I have discussed in other lectures.

The formulæ I have supplied doubtless subserve

(*a*) Sold by the British Drug Houses at 3s. 8d. per gallon.
(*b*) Since writing this I have succeeded in preparing a very satisfactory and cheap emulsion.

useful functions but every up-to-date practitioner ought to have the percentage composition of the ordinary foods employed in infant-feeding so completely at his finger-ends, that, under any given conditions, he can devise or correct formulas for himself.

In order that practitioners may be able to make such manipulations for themselves, I append here the average percentage composition of dried milks, and their caloric values; and also the percentage composition and caloric value of cream, Marylebone cream, and sugar:—

Percentage Composition.

Article.	*Proteins.* Casein-ogen.	Whey Proteins.	*Sugar.*	*Fat.*	Approximate Caloric Value per Gramme.	Ounce.
					Calories.	Calories.
Dried Milk—						
Full cream	24.50	1.94	38.92	28.00	5	146
Half cream	30.58	2.42	39.70	15.10	4	119
Separated	31.40	2.49	55.00	1.00	4	104
Whey powder	—	14.25	74.50	0.27	4	102
Thick cream (46 per cent.)	—	—	3.00	46.00	4	122
Thin cream (16 per cent.)	—	—	4.00	16.00	2	48
Marylebone cream	—	—	—	50.00	5	127

I almost hesitate to give directions for the quantity of any of the milk mixtures prepared in accordance with the formulæ I have supplied, or with those devised by the reader, to be given to any particular infant. All quantities must be based on the physiological requirements of the individual.

As a rough basis for calculation it may be assumed that a normal infant, living under normal conditions and of the age of three months, requires from 40-50 calories per pound of body weight. That is to say, an infant of this age, weighing 10 lbs., requires an amount of food of the value of 400-500 calories in the 24 hours. Younger and smaller infants require a rather larger number of calories per pound of body weight, and older and larger infants rather less. From these data it is comparatively easy to adjust the quantity of food to the requirements of different infants, full allowance being made for special conditions. For instance, more food is required in cold weather, and when the infant is growing rapidly and manifesting great muscular activity than in hot weather when it increases in weight slowly and is inactive.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by F. Legeu, M.D., Surgeon to the Tenon Hospital, Paris. Subject: "The Age for Prostatectomy."*

ORIGINAL PAPERS.

LACERATIONS OF THE PERINÆUM AND THEIR TREATMENT. (a)

By E. HASTINGS TWEEDY, F.R.C.P.I.,
Gynæcologist to Dr. Steevens' Hospital, Dublin.

This subject has received but scant attention of late years, and the general belief is that the last word has been said concerning it. Yet even to-day there obtains a vast difference of opinion as regards details of treatment. These differences are much too important to be ignored, for, in truth, they depend on fundamental principles of obstetrics, principles which are fast being lost sight of because of the very perfection of our surgical art.

It was formerly taught that tears of the perinæum occurred as a mere splitting through the median raphe, and their importance was gauged by their length. The old classification of three degrees of tear is still reproduced in text-books, and remains a dogma which has long since outlived its meaning.

The classical symptoms associated with partial rupture of the perinæum are not dependent on the extent of the median rupture, but rather on the severity of the lesion in the levator ani muscles.

These muscles have been aptly compared to a sling the thong of which is represented by the perinæum.

Were a sling loaded with a breaking force, it is obvious that its dissolution must take place in one of three directions: (1) Rupture might occur through the centre of the thong; (2) one or both lateral supports might give way; (3) these lateral supports without actually breaking might be dragged from their attachments to the thong. Similarly, lesions of the perinæum may occur in these three different directions, but whilst the first and second varieties are very rare, the last, *i.e.*, tearing of the muscle away from its perineal attachment, is very common.

I do not know how far it is recognised that the muscle fibres are seldom snapped asunder, but that in the majority of cases they are torn from their insertion into the perinæum. Such a catastrophe will leave the skin and superficial fascia intact, and it is the rule rather than the exception to see vigorous and misdirected efforts made to support the perinæum at a period long after its tearing has actually occurred.

The intimate connection between the muscle and mucous membrane causes both structures to give way together, and such tearing is almost invariably followed by a slight flow of blood. This blood is often confused with the "show," but it should rather be looked upon as a certain indication, not that the perinæum will tear, but rather that it has already torn.

The retraction of the muscle away from the perinæum can be easily demonstrated by inserting a finger through the vulva during a pain. If one feels inclined to adopt a suggestion recently put forward as a means of preserving the perinæum, an object lesson pointing to a similar conclusion can be learned. The plan I allude to is the fixing of a wide cross-stitch into the thinned-out perinæum before the skin has ruptured. This is supposed to afford support, and failing such support it is said to provide a properly placed suture for closing the laceration. It is needless to say that this device fails in both its objects. It does not prevent the tear, nor will it be found to hold within its grip any more important structures than skin and superficial fascia, proof positive that the muscles have already separated before the skin lesion occurs.

Support of the perinæum as carried out in the Rotunda Hospital is a rational and useful procedure. It cannot do harm, and it probably does much good. To make it effective, however, it is necessary to bring it into operation before the blood flow occurs.

The thinly stretched-out perineal skin, deprived of its underlying supports, rarely escapes uninjured from the subsequent processes of labour.

(a) A paper read before the Section of Obstetrics, Royal Academy of Medicine in Ireland, February 6, 1914.

A clear view of the tear can be obtained immediately after the birth by adopting the following manœuvre :—

The left arm is passed between the legs from before backwards whilst yet the patient is on the side. Three or four fingers of the corresponding hand enter the vagina, and are turned so as to make their knuckles look toward the anus ; a wide speculum is thus formed which holds forward on its palmar surface the cord and membranes.

The Y-shaped laceration is now clearly seen with its deep lateral sulci forming the arms of the Y, which arms are separated by an œdematous tongue of mucous membrane, part of the back wall of the vagina. If the apex of the tongue be now pressed by the middle finger up toward the cervix the full extent of the raw surface becomes apparent and the ragged muscle ends can be made out. It is clear that the most perfect anatomical reunion will not occur unless the upper and lower surfaces can be united throughout their widest extent and that any closure of the vaginal mucous membrane preliminary to deep suturing must diminish this area, and prevent the approximation of important muscle bundles.

Diminution of this area was at one time thought to be an important advance in treatment as it lessened the amount of tissue gripped by the perineal sutures, but the fallacy of this belief is now very apparent.

Many still employ separate sutures for the mucous membrane, and claim that a more accurate adaptation of parts can thereby be procured, and a more perfect barrier against infection from lochial discharges be obtained.

My former colleague in the Rotunda Hospital, Dr. T. H. Wilson, now Professor of Midwifery in Dublin University, was a firm believer in the advantages obtained by these sutures, and differed in this respect from all his predecessors so far as I could ascertain. I watched his results with close attention and formed a very definite opinion that no justification existed for the belief that suppuration was rendered less likely by the presence of vaginal sutures ; on the other hand, I have often seen deep suppurating tracts result from the insertion of buried catgut into the vaginal tears. Furthermore, the muscle fibres which lie to the outer borders of these mucous membrane rents are not placed in a position anatomically correct when fastened to the side of the mucous membrane tongue. My greatest objection, however, to the closure of the lateral sulci as a separate proceeding is that their closure involves the placing of the patient in the cross-bed position and nearly always calls for the administration of an anæsthetic. Such exposure and disturbance come at a time when it is most desirable to keep the patient quiet and at rest. There are many serious objections to the employment of the cross-bed position when it can be avoided. It most certainly increases labour shock, exposes the patient to cold, and is very frightening. To perform an aseptic operation in this position requires the presence of many assistants. Without such help it is very hard to satisfy the requirements of surgical cleanliness, and I have never seen a perinæum stitched in this manner under the conditions which obtain in a private house where these requirements were satisfied. The operator's hands, instruments, or ligatures are almost certain to come into contact with structures far removed from surgical cleanliness. The position is more fitted to the consultant whose chief work is performed amidst the costly surroundings of a modern operating theatre than to the practising obstetrician.

It is my custom to suture the perinæum immediately after the infant has been severed from its cord and before the fingers employed for exploring the wound have been withdrawn.

At this time the patient has not fully recovered from the effects of the anæsthetic, and can be kept from embarrassing movements by the arm held between her legs. If stout unchromicised catgut be used, no necessity will arise for cutting out the sutures, and the patient need never be aware of the fact that she has been torn.

A large needle three inches long, with a curve which falls just short of a semi-circle, is held in the hand without the aid of a needle-holder. It is threaded with a long suture, the end of which is wound round the little finger to keep it clean. The needle point is entered at the skin edge of the posterior extremity of the wound. It is then rotated so as to make its concave surface look toward the floor. This enables it to sink deeply into the lateral tissues, and when it has sufficiently accomplished this purpose it is again rotated and pushed on until it lies beneath the tip of the index finger, the one which holds back the base of the tongue of mucous membrane. It now pentrates deeply into the upper raw surface and is brought out through the skin at a point which corresponds to its entrance. The second suture is placed in position about half-an-inch in front of the first one. It pierces the apex of the tongue before crossing to the upper surface. Other stitches similarly may be placed in position, and each will enfold a smaller amount of tissue than its predecessor.

It will be noted that all sutures lie parallel to the bowel, and the latter consequently is in no danger of injury.

This operation appears to me to approach very closely the ideal in obstetrics, for with minimum effort maximum results are obtained. The plan permits of full exposure of the raw surfaces. Aseptic difficulties are absent. The direction of the sutures, which are made to run parallel to the bowel, precludes the possibility of its injury, and success depends on one's own efforts, not on that of the assistants.

The best results in obstetrical practice are not obtained by costly surgical appliances, and it is upon the recognition of this fact that the success of the Dublin school has been built. No published figures from any obstetrical hospital approach the Rotunda in lowness of morbidity percentage, and in no other institution are the efforts of Nature exploited to a greater extent. In proof of this assertion, I need only point to the incidence of persistent occipito-posterior position. A comparison of figures will show that forceps is less often applied to overcome this abnormality in Dublin than elsewhere, and failure in normal rotation is observed in less than 1 per cent. of infants born. Similarly throughout the whole history of the Hospital there has been shown a clear appreciation of the limitations of surgery.

Obstetrical surgery does not run on lines parallel with those of general surgery, and this elementary principle should not be lost sight of.

The general surgeon surrounds himself with elaborate paraphernalia and relies greatly upon the co-operation of his assistants. He can afford to finish his work to its most minute detail, and can with impunity permit himself mental lapses which might spell disaster in midwifery practice. In the latter the actor relies wholly on himself. He has to perform his part without any stage properties, and win success despite of adverse surroundings. In order to do so, his resources must be skilfully husbanded, and, discarding the mere trimmings of his art, he must hold firmly by the essentials.

I must not be taken as condemning the scientific arrangements available in the modern up-to-date hospital. In such hospitals it is possible to demonstrate the brilliancy of obstetrical surgery, and to show how fool-proof the conduct of a normal delivery can be made. Nevertheless it remains true that unnecessary interference cannot be practised even in these aseptic institutions without increasing the morbidity percentage rate.

The secondary repair of incomplete lacerations can be accomplished with great certainty and ease by a slight modification of the original Lawson Tait operation.

After the preliminary incision the scissors should be laid aside and not again used ; the deepening of the raw surfaces can be more quickly and safely accomplished by a gauze wipe, or by the gloved fingers. The separation follows the direction of the original tear, that is to say, the apex of the tongue remains adherent to the rectum whilst deep sulci are opened

up at either side of the bowel. The muscle bundles occupy the outer edges of these surfaces, and if they are brought together by deep sutures a perfect repair is accomplished. The method of blunt dissection obviates the necessity of passing a finger into the rectum, and is perfectly free from danger to the bowel. It makes the operation almost bloodless, for it is often a matter of amazement to see how large are the vessels laid bare without being ruptured. The directions previously given for inserting sutures should be followed, but when the needle has taken up a thick, lateral mass of tissue it is best to make it cross the rectum and follow the course recommended by Tait. The last of the three cross-stitches should hold in its grip thick lateral masses of tissue, and must not be inserted through any thin skin flap. The danger of narrowing the vulvar orifice to too great an extent will be thus avoided, and any raw surface which remains may be closed by one or two superficial catgut sutures passed from above downwards.

I do not care to operate on secondary repair until the expiration of two months after the birth of the child. Before this time the parts are soft and vascular, and have not completed their full involution.

In rare cases of operative delivery, the fibres of the levator muscles are snapped in two, and not merely torn from their insertions. The laceration will then assume alarming proportions. It may extend up the vagina to the cervix and leave the rectum bare of all attachments, save those connected with its posterior wall. The sphincter usually escapes destruction, and is seen to cross this gaping cavity in a clear dissection. Hirst describes a very severe laceration of this nature where he was enabled to see clearly the obturator foramen. The perineal tear in these cases is not placed in the mid line, but passes to one side of the raphe.

Under such untoward conditions success in treatment will depend on our ability to reunite the muscle bundles, and a painstaking effort to do so will usually yield favourable results.

In complete laceration of the perinæum the levator ani muscles are never torn, and therefore none of the symptoms associated with incomplete tear arise. The muscles though separated are functioning perfectly. They remain enclosed in their intact sheaths, and obtain their points of resistance from the portions which still remain united at the median raphe. The cardinal factor in the cure consists in the efficient approximation of the severed ends of the sphincter muscle.

The immediate operation consists in stitching the torn bowel with interrupted catgut sutures in such a way as to make the knots occur on its inner lumen. Then the sphincter ends are joined by two sutures, the first of which is placed to the side of the anus and on a level with its back wall. It passes through the portion of the muscle nearest the skin. The second one placed half-an-inch above the first embraces the deep border of the muscle. Both should pierce the outer coats of the rectum as they are passed across it, before entering the corresponding tissues at its other side. The perinæum proper is then to be attended to, and it is not necessary in this instance to gather up deep lateral masses of tissue, for the levator muscles not being retracted can easily be brought together. To perform this repair it is easier to have the patient placed in the cross-bed position than on the side, but when conditions are not favourable as regards assistants and surgical cleanliness, the side position is much to be preferred.

The secondary repair is carried out on precisely similar lines and the Lawson Tait incisions enable it to be accomplished in a very perfect manner. Howard Kelly's suggestions for the after treatment of complete tears are of the utmost value. He keeps the bowels confined for many days by giving opium and excluding all food, save albumin water, and this in small amounts. When the bowels are subsequently moved by an injection of olive oil the fæcal accumulation will be quite small.

An important point remains to be dealt with, namely, the time best suited for the repair operation.

In recent tears immediate union is theoretically the best, but in practice a cure may with equal confidence be looked for at the expiration of eight or ten hours, and indeed granulating surfaces brought together on the eighth day heal with great certainty.

NERVES IN ILLNESS. (a)

By PRESTON KING, M.D.

The title of my paper for this evening may sound little vague and perhaps rather comprehensive. I am not proposing, however, to discuss even briefly the diseases of the nervous system, so that any anxiety on that score may at once be set at rest. And if the title is comprehensive, it has in that fact this advantage, that I shall be able to say all I want without wandering beyond its scope.

By "nerves" I mean not only those of sensation, but also and more especially the whole nervous organism with its higher psychic centres. For I want to speak especially of the influence that the mind has upon the body, and how it can at times be used in the treatment of disease.

What I have to say is in part the result of observing illness in others throughout several years of practice, and in part the outcome of my own personal experience of disease. Of these two fields for investigation I would lay more emphasis upon the latter, for no one can know the fine abnormalities of "nerves in illness," and the influence of the mind, better than the man who has been ill himself; and if that man happens to be a doctor, and can therefore bring a scientific training to bear upon his case, I think his experience in this matter, however feebly expressed, is worthy of attention.

In this connection I would remind you of the words of Oliver Wendell Holmes in his "Morning Call":

"'Tis a small matter in your neighbour's case
To charge your fee for showing him your face.
You skip upstairs, enquire, inspect, and touch,
Prescribe, take leave, and off to twenty such.

"But change the time, the person and the place
And be yourself the interesting case,
You'll gain some knowledge which 'tis well to learn;
In future practice it will serve your turn."

If the knowledge that we gain at our own bedside teaches us nothing else, it at least helps us to see ourselves as our patient sees us, so that we are the better able to appreciate his feelings and to sympathise with him in his illness.

I think we are too apt sometimes to dismiss as of little or no account much that our patient tells us of his symptoms and sensations, partly because these are not consistent with our own ideas about his case, and partly because they form no part of the text books' description of his illness. Books of necessity describe diseases as distinct, but they do not help us to read between the lines of the notes of our patient's case; experience alone enables us to do this. In health no two individuals are alike, and in illness they therefore cannot be expected to be the same, though suffering from the same disease. We should do well to remember this when we speak of medicine as a science.

As there is no science of human nature, for no two individuals will be certain to act the same under similar circumstances, so there is no science of medicine, for we know that each case has to be treated differently.

Medicine is an Art, the application of all sciences, and the unknown factor of our patient's mental state, and of his nerves for the time being, is what we have to solve, if we would discover his personal equation, and be in a position therefore to treat him properly.

It is not the physical defects of his various organs only that we have to treat, but the whole man with his personal and pathological peculiarities. In doing all this, in discovering *who* as well as *what* we have to

(a) Read before the Bath Clinical Society, February 6th, 1914.

treat, our patient will often help us if we let him talk and tell us of his various feelings and ideas. Much that he says will in itself be of little importance, and very often based upon remarkable views of anatomy and pathology, but the talking will do him good, and, if we listen sympathetically, we shall not only learn the man we have to deal with, but also shall have gone a long way towards gaining his confidence, and as we all know, this is essential for the proper treatment of any case.

It is the impossibility of such sympathy occurring between the doctor and his patients that makes contract practice bad; in this, by the very nature of things, the patient is a case, and a case alone, and time does not allow for the finding of the individual. Before speaking of "nerves in illness" in a more general sense, and the effect of the mind in certain constitutional diseases, I want to say a few words about the functional disturbance of some of the sense organs in illness.

Generally the disturbance takes the form of hypersensitiveness, and when the nerves of hearing are involved this may be a cause of real distress. The sick-room should be quiet. Our patient should see us by his bedside before he knows that we are in the house. What has to be said should be spoken in quiet tones, but above all with no attempt at keeping from him what we are saying. He is sensitive, he is perhaps suspicious, and he is apt to conclude that what he is not wanted to hear is of the most untoward import. The whispered voices of his nurse and doctor may disturb him, and mingle with his waking dreams, where their outspoken words would hardly be perceived. I know the truth of this, for I have experienced it myself.

Further it is well always to assume that our patient, though he takes no notice, can hear and understand, and nothing therefore should be said in his presence that we mind his knowing. The sense of smell is often abnormally acute in illness; you who indulge in smoke would do well to remember this; and further I would urge you not to use carbolic soap, for the patient is sure to think that you have just come from an infectious case. The cutaneous nerves are similarly hypersensitive, especially in the direction of heat and cold. A member of our profession in this city has today a fine warm pair of motor gloves, given him by a lady patient, for he touched her, and his hands were cold.

With regard to the eye, hypersensitiveness to light in nearly all acute diseases is sufficiently well known. Delusions of vision are due rather to changes in the seeing centres of the brain than to the eye itself, and I would remark in passing that the figures that are seen are very real. Of snakes and animals I cannot speak from personal experience, but the people that I saw were apparently just ordinary people, not thin, shadowy ghosts, but real solid men and women, who obscured the furniture behind them. I have seen them and I know.

I pass on now to consider the influence of the mind in certain states of illness.

In asthma and hay fever the nervous element will be allowed by all, and I need not enlarge upon it here. In nettlerash, too, in which some old authors saw a connection with asthma, the nervous factor may be marked. I suffered from this irritating disease for two years; it used to come out for about half an hour at a time once in twenty-four hours, getting daily later in its advent, till it had gone the round of the clock, when it would start again. Diet had no influence upon it, and medicines less, until I saw Dr. Stainer, the skin specialist, of St. Thomas' Hospital, who suggested a nervous element and prescribed aspirin, which had an immediate and marked effect for good.

A case of hysterical hip, where morphia had to be given for the pain, and where no organic disease was found when the joint was opened at St. Thomas's Hospital, after I had tried in vain for weeks to cure it, and they had had the case under observation for a month, and where a cure took place suddenly on a voyage to the Cape, occurs to me as a case of "nerves in illness." A few weeks ago I saw a case of hysterical deafness, the only one I remember to have ever met with. The deafness was very real, and was, I am convinced, of mental origin, for, among other things, it would alternate for a few weeks at a time with the most acute hearing, when the ticking of the clock and the singing of the birds were a cause of real distress.

These cases I know you will say were of orthodox hysteria. But what is hysteria? Are not the cases we class under this disease just those in which the real cause is an abnormal working of the psychic centres, those in which the mental factor is at fault, and in which, when other treatments fail, we should try suggestion, and attempt a cure through the influence of the mind?

As the best example of the general effect of "nerves in illness," I would instance influenza. Those of us who have had it can fully appreciate the feelings of the Judge who, recovering from this disease, told another Judge that if he argued with him he would cry. There is nearly always a more or less marked nervous depression accompanying or following influenza. A case of this kind was that of a young curate who, on first getting out, had his wideawake hat tied under his chin with bootlaces "to keep his head warm," and who had always six or more pairs of socks airing on the fender.

In another case a man on taking his first walk would say that he envied the occupant of a hearse he had met on its way to the cemetery. These two cases both recovered with sympathetic treatment, but others—and we have all known them—drift into profound and hopeless melancholia, and end in one of our houses for the treatment of the insane.

It is during convalescence from this and other forms of illness, when the patient's nerves have not yet recovered the normal tone, that a cheerful word or the reverse has an instant effect for good or bad. Someone says "I am glad to see you looking better," and you feel better at once; or on the other hand he says "I am sorry to see you looking so ill," and you feel inclined to creep home and die. So great is the effect of mind over matter, of the mental state on the body's welfare. Who will deny this influence of the mind for good or evil on the body's health? Only those, I think, who have never been ill themselves, or those who have never given the question any proper thought.

A doctor cannot treat himself if he is ill, nor can he treat his family; he may give the self same medicine that another would, but he cannot put into the bottle those all-important ingredients, suggestion and faith, or prescribe for the mental factor as the other can. Do we not every day, consciously or unconsciously, use suggestion in our practice? I think we should do well to use it more.

Years ago when I was an assistant in another town I was asked by an old lady what good I thought my visits were since I gave her no medicine. She had nothing the matter with her of orthodox disease, but I found that my principal had been giving her a mixture of burnt sugar and water, and not the best sugar at that. I prided myself on my honesty at the time, because I did not prescribe for her imaginary ailments, but now I regret my folly, and not folly only by loss of personal gain, but more especially folly because I withheld the sugar and water which did her good. I had not then learnt the truth about "nerves in illness," or I should have prescribed the bottle of suggestion that she wanted.

The employment of suggestion in the treatment of disease is, I know, apt to be abused, and has been so abused in the hands of the charlatan and the quack, but this it seems to me is no argument against its proper use. Do we fear to prescribe opium or alcohol when they are needed? And yet the abuse of these, and especially of the latter, is a far more present danger than suggestion ever could be.

A case in my own experience in which suggestion succeeded beyond my expectation occurred some years ago. The patient was a distant cousin of my own, a boy of eight. He had been operated on for empyema, but the tube had been removed and, surgically, all was

well, though he was desperately ill and very weak. This small boy, who, by the way, was not my patient, had always been very fond of me, for I had known him from a child, and he had the most absolute confidence in all I said. I was staying in the house with his parents on the night of which I speak, and as he had been kept awake for days by the pain he suffered, till his father said he almost wished that he might die, I said I would try what suggestion might do for him. When I entered his room he was throwing himself about and crying out in pain. I stood by his bedside and, for a quarter of an hour, in a quiet, monotonous voice, kept telling him that he had got no pain, and that what pain he had been having was taken away that afternoon with the tube we had removed. He assured me that he had pain, but I persisted in what I was saying, and continued telling him that the pain was gone, till at the end of the quarter of an hour he became quiet, and, shortly after, slept; from that time onwards there was no return of the pain, and convalescence was in the end complete. He had got into a habit of pain, his will power was in abeyance through his illness, and he needed another's healthy mental state to aid his own, and the absolute confidence he had in me was essential for this help to work.

In another case more recently, of insomnia, an understanding between my patient and myself that at a certain hour I should be telling her to sleep, was successful beyond my hope. It worked upon the first occasion, and too often afterwards to be disposed of as a mere coincidence. On one occasion my patient told me that I had not thought of her until half an hour later than the time arranged; she was quite right, I had been out to dinner, and had forgotten. I do not pretend to explain this. I only tell you of the facts. It may be it was all subjective upon her part. It may be that it was due to telepathy. I mention these cases as they seem to have a distinct bearing upon the subject of "nerves in illness." I want to pass on now to say a few words upon the question as to how much of the truth about their chance of recovery we should tell our patients.

As to the friends, they should be told our opinion, and all that we can tell them, absolutely and without reserve. But for the patient himself is it not otherwise? Should we ever tell him that there is no hope of his recovery? I think not. I feel very strongly we should not, save in most exceptional cases.

Our duty is to save, or if we cannot do that, at least, to prolong life; and do we not all know cases where the course can only be slowly downwards, and in which a knowledge of the truth would inevitably hasten the end? I do not mean for a moment that we should say what is not true, but I do say that when other means have failed we should still make use of the mental factor, and encourage hope. I have never found it necessary to tell my patient that he is dying; he has known it soon enough. Oliver Wendell Holmes is very explicit on this point. He says:—

"A physician is not—at least ought not to be—an executioner, and a sentence of death on his face is as bad as a warrant signed by the governor. As a general rule, no man has a right to tell another by word or look that he is going to die. It may be necessary in some extreme cases; but as a rule it is the last extreme of impertinence that one human being can offer to another. . . . If we only let Nature and the God of Nature alone, persons will commonly learn their condition as early as they ought to know it, and not be cheated out of their natural birthright of hope of recovery."

I feel sure in my own case, when I was suffering from double pneumonia, when by all the rules I should not have outlived the night, when my doctor felt practically sure that he would not see me in the morning, that if he had told me what was in his mind, not only should I not be speaking to you now, but I should have died during that night just over twenty years ago. But my doctor had not told me what he thought, and so had let me retain my birthright of hope. It was not his silence only, though, that saved me, but another's spoken words who told me I was dying. For the intense anger which I felt at what he said and at what seemed to me his ignorance and his folly—for how did he know, I argued, and in any case the crisis was not due so I fancied, for two days yet, seemed to awake the dormant mind and rouse me from the apathy in which I lay, bringing out in truth the influence of "nerves in illness," for I began to recover from that time.

If we only knew when and how to apply the stimulus of excitement, as it was applied to me, I think we might sometimes rouse our patient from that apathy and torpor in which he lies, and through which he is drifting on into the Infinite. I think, too, on the other hand, that there are states of mental excitement in acute disease when the soothing influence of music might act as a powerful therapeutic sedative. If by music we

"Wake the sounds that cannot lie for all their sweet beguiling
The language we need fathom not, but only hear and feel,"

we might produce results through the influence of the mind which are entirely beyond our grasp by other means.

As a profession we probably have never yet fully recognised the importance of the mind, conscious and subconscious, as one of our most powerful therapeutic agents in the treatment of disease.

NOTES OF TWO CASES OF RHEUMATISM TREATED WITH RHEUMATISM PHYLACOGEN.

By J. D. GILRUTH, M.A., M.D.Edin.,
Surgeon, Arbroath Infirmary.

Case 1.—R. W., male, æt. 35.—Admitted to infirmary December 7th, 1912.

Previous History:—Patient, a healthy man up till ten years ago; when following his trade in London he contracted rheumatism in his feet. For three weeks he followed his work in a crippled condition and then came north. After coming home he was much worse and was confined to bed for four months. His condition afterwards improved, but he was never quite rid of the trouble. Two years ago he had another attack and was confined to bed for six months, and he was worse in the warm weather—arms, legs and neck all being attacked. Treated with all the usual remedies without result.

Condition on admission:—Patient admitted to ward on date stated, in a crippled condition, unable to turn head, his left arm practically useless, knees bent and unable to go about without the aid of sticks. Patient had no history of gonorrhœa or any cause otherwise tending to rheumatism. No heart murmur, kidneys functionating well, slightly anæmic, has pasty colour of face.

Treatment:—Thyroid gland was commenced on January 16th, 1913, and continued for some weeks without result.

On February 18th, treatment was commenced with Rheumatism Phylacogen, when 5 c.c. were injected, the injections being continued thus:—5 c.c. on February 26th, 5 c.c. on March 1st, 5 c.c. on the 4th, 5 c.c. on the 5th, 6 c.c. on the 7th, 6 c.c. on the 9th, 6 c.c. on the 13th, 7 c.c. on the 17th; 50 c.c. in all being administered. The following are the notes of the case from February 26th onwards. Injection administered in arm at 1 p.m.; during afternoon arm got stiff, red and very much swelled, temperature (previously running between 97.5 and 99) rising after 6 p.m. to 100.9. 27th: Patient complained of being stiff all over. 28th: Arm almost normal, patient feel-

ing better. March 1st: Injection in the other arm at 2 p.m.; temperature at 6 p.m. 100; a little redness round point of injection, not so bad as on the 27th, also stiffness and swelling. March 2nd: Symptoms subsiding and patient feels more supple. March 3rd: arm normal. March 4th: Injection in left thigh at 2 p.m.; temperature at 6 p.m. 99.2, a little redness and swelling and also stiffness. March 5th: Patient feels more supple, very little discomfort in leg; injection in right hip at 2 p.m.; temperature at 6 p.m. 101. March 6th: Swelling, redness and stiffness all over, more so than after the previous injections, temperature at 6 p.m. 99. March 7th: Morning temperature 97.4, local symptoms much better and movement better all over; patient had injection in right shoulder at 2.30 p.m.; temperature at 6 p.m. 100.8, a little redness and swelling and a good deal of stiffness. March 8th: Temperature normal, patient feeling much better. March 9th: Patient still better, can raise his left arm higher than he has done for two years; injection in left shoulder at 6.30 p.m. March 10th: Temperature at 3 a.m. 99.8, still a little pain where injection was given, but feels better on the whole; temperature at 6 p.m. 99.6. March 11th: Temperature normal, patient feels much better. March 12th: Patient feels better in every way. March 13th: Patient feels much better; injection at 9 p.m. March 14th: Temperature at 3 a.m. 99.2, hardly any local reaction. March 17th: Patient moves about a little and walks ever so much better, holding himself straighter than he has done for two years. March 18th: Owing to the inmates of the infirmary having vacated to temporary premises, clinical notes discontinued. Patient went to a convalescent home on the 26th, feeling very much better. Seen on April 23rd, was in good health, free from pain and intends starting work immediately. August 4th: Patient has been at work since May and continues quite well. January 5th, 1914: Patient has continued quite well. He is out of town now, but I have never heard of him having any relapse.

CASE 2.—B.S., female, æt. 37.

Previous history:—Patient has suffered from anæmia since she was 21. Two years ago she was affected with a very bad cold which developed into rheumatism, both arms and hands becoming very stiff, it being almost impossible for her to use her fingers. The stiffness next attacked her legs, and gradually every joint in her body became affected. Every available remedy—salicylates, opium, iodides and many other drugs—was tried without much success. Patient went to Edinburgh and received hospital treatment for a period of nine weeks, treatment consisting of massage, cataphoresis and generally, hygiene and diet. She returned home a good deal better, but in the course of a very short time again became very stiff and simply dragged herself along at her work

Treatment:—Patient was admitted to the infirmary on February 17th in a very crippled condition. Phylacogen treatment was commenced on February 26th, 5 c.c. being injected in the right arm. A slight rise of the temperature followed, arm a little swollen, with a good deal of redness and stiffness. February 27th: Arm much better, patient feels much more supple all over. February 28th: Arm almost well, but patient complained of ankles, right knee and arms being more stiff than usual. March 1st: 5 c.c. Phylacogen in left arm at 2 p.m.; redness, stiffness and swelling came on gradually, temperature at 6 p.m. 100. March 4th: 5 c.c. Phylacogen in left hip at 2 p.m.; a little redness, swelling and stiffness, not so severe as when given in arm; temperature at 6 p.m. 99.8. March 6th: 6 c.c. Phylacogen in right hip at 2 p.m.; local symptoms much the same but feels better all over, temperature at 6 p.m. 99.8. March 7th: Temperature sub-normal, patient feels better, local symptoms subsiding. March 8th: 6 c.c. Phylacogen in right shoulder at 2 p.m.; 6 p.m. temperature 99.6; stiffness, redness and swelling not so bad as previously, but patient feels like a log, not able to move. March 9th: The early part of the day patient feels very stiff and so heavy cannot move without help, towards evening much better and able to sit up again. March 10th: Much about the same till evening, when she finds it impossible to move right leg; ankle very painful, also right leg, patient screams on ankle being moved. March 11th: Temperature normal, patient feeling better; 6 c.c. Phylacogen injected at 7 p.m. March 13th: Patient feels joints better; 6 c.c. Phylacogen at 8 p.m.; site of injection a little painful, no redness or swelling and no increase of temperature. March 14th: Temperature normal, patient feels very little discomfort. March 15th: Patient feels much better; 6 c.c. Phylacogen injected at 8 p.m., no rise in temperature, but swelling, redness and pain. March 16th: Patient feels better. March 17th: Patient feels very well, up, and seemed much better; 7 c.c. Phylacogen at 8 p.m. March 18th: Temperature at 3 a.m. 100, a little swelling and redness. March 20th: 8 c.c. at 8.30 p.m.; temperature normal. March 22nd: 10 c.c.; temperature 99.9. March 25th: 10 c.c., temperature 99.4. March 31st: 10 c.c. at 11 a.m., temperature at 6 p.m. 99.8. April 2nd: 10 c.c. at 2.30 p.m.; temperature 99.4. April 4th: 10 c.c. at 8 p.m.; temperature 100.2. From March 18th no detailed clinical notes were taken. There was always considerable pain and swelling locally, but on the other hand in 48 hours there was an increased feeling of well-being and freedom from pain. The period of reaction coincided with the rise of temperature, and only very seldom was the pulse rate increased.

The patient left hospital on April 10th, feeling much better. Seen on April 23rd, she walked freely and expressed herself as being much better in every way. During May patient had a relapse and was subsequently treated at home, receiving the following injections: 5 c.c. on May 30th, 5 c.c. on June 2nd, 5 c.c. on June 6th, 6 c.c. June 9th, 7 c.c. June 12th, 7 c.c. June 15th, 7 c.c. June 18th, 8 c.c. June 21st, 8 c.c. June 24th, 8 c.c. June 29th, 8 c.c. June 30th, 8 c.c. July 4th, 9 c.c. July 7th, 10 c.c. July 10th. The temperature varied from 99 to 102. July 12th, patient felt very well, walked two miles, very little stiffness. August 4th, patient is better than she has been for years—she walked six miles one day last week, and is now about to return to work.

January 5th, 1914:—Patient returned to work in August and has remained quite well ever since. The stiffness of the ankles entirely disappeared, and about a month ago I saw her coming down a steep road showing no signs of her old halting walk. She is convinced, as I am, that but for the Phylacogen she would have been in her old condition of helplessness.

CLINICAL RECORDS.

PARAFFINUM FLUIDUM IN GASTRIC ULCER.

BY J. C. McWALTER, M.D., F.R.F.P. and S.

GASTRIC ulcer we have always with us, and all the cases cannot be operated on. There is a clamant cry for relief, and the classical mixture of bismuth and

morphine has probably been given oftener than ever since the Insurance Act came into operation.

With such a mixture oxalate of cerium is of immense value when hunger pain prevails, and the present note is to urge the importance of using paraffinum fluidum also.

Probably its effects are purely physical and mechanical, but I find that where say two ounces of pure fluid paraffin is added to the ordinary eight-ounce bottle of bismuth mixture, the constipation which otherwise results is prevented, and the ulcerated surface appears to heal with greater rapidity. Paraffinum fluidum, given with sodium salicylate, also seems useful in cases of threatened appenditicis, though possibly only as an intestinal lubricant.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Appendicitis Complicated with Ureteral Calculus.—Mr. Arthur Edmunds operated on a man, æt. 22, who had been sent to the hospital as a case of acute appendicitis. The history of the case as at first given by the patient comprised the usual symptoms of an acute onset, abdominal pain centred in the right iliac fossa and vomiting. On examining his abdomen the right rectus was found to be rigid, but no tumour could be felt. There was tenderness over the right iliac fossa, but there was a spot even more tender in the loin just below the last rib. The patient was obviously ill: his temperature and pulse were raised, his tongue furred. The tender spot in the loin excited suspicion, and under cross-examination the patient remembered that he had had a previous attack, in the course of which he had passed blood in his water. The diagnosis arrived at was that the case was one of appendicitis, but that in view of the tenderness in the loin and the history of hæmaturia it was possible that the patient had a stone in his ureter. Several courses presented themselves: in the first place the operation might be postponed until more thorough investigation by X-rays and the cystoscope had thrown some more light on the case. As it was late at night, and this would have entailed postponing operation for at least twenty-four hours, this course was not considered advisable; in the second place, the appendix might be removed, and later on the urinary tract might be thoroughly investigated; and in the third place, the appendix might be removed and the ureter explored as far as possible through the abdominal incision, the nature of the treatment to be carried out being left to be decided on later on during the course of the operation. This plan was ultimately carried out.

An incision was accordingly made at the outer border of the right rectus, the appendix exposed, and found to be the seat of a slight recent attack of inflammation and of considerable chronic mischief. It was removed in the ordinary way. In the course of opening the abdomen the retro-peritoneal tissue was found to be œdematous, and on feeling along the course of the ureter a hard nodule was found about the size of the last joint of the finger, situated low down in the pelvis close to the bladder. Keeping one hand within the abdomen to serve as a guide, the peritoneum was then reflected inwards until the nodule was thoroughly exposed retro-peritoneally. This was somewhat difficult on account of its depth, but by prolonging the incision downwards and retracting the edges of the wound, a satisfactory access was ultimately obtained. The peritoneum was then closed and some gauze temporarily packed into the upper part of the wound over the peritoneal incision. The nodule was then fixed between two fingers of the left hand and the point of a scalpel passed between the fingers thrust into it. It was then quite obvious that the nodule was an impacted ureteral calculus. The ureter was then carefully incised over the stone, which, after a good deal of difficulty, was safely removed. The difficulties met with on removing the stone were due to the fact that it was very firmly impacted at such a depth that all the manipulations had to be guided by touch and not by sight. No attempt at suture of the ureter was possible; a drainage tube was passed down behind the peritoneum. It was noticed that this tube pressed unduly on the iliac vessels, and to avoid this the peritoneum was reflected from the back of the right rectus and the tube brought out through the muscle close to the middle line. A small tube was put into the upper end of the wound to protect the peritoneal incision and the wound closed.

Mr. Edmunds said this case illustrates the frequency with which an operation for appendicitis reveals the presence of some other intra-abdominal disorder, either dependent upon the appendicitis or quite unconnected with it. It is a common surgical experience that the removal of an appendix does not cure the patient; there are discomforts due to the formation of adhesions and to the injury which must of necessity be done to the abdomen. These are to a certain extent inevitable, although care in covering all raw surfaces of the peritoneum and general operative dexterity will minimise them. There remain, however, the cases in which the appendix has not been the source of a patient's illness, and in these cases it is hardly to be wondered at that appendicectomy does no good. There is finally the group of cases in which, although there is definite appendicitis, other conditions exist. During the past twelve months he had come across three cases in which there was unsuspected cholelithiasis, and in two of them ovarian cysts were present as well. In other patients such conditions as angulation of the colon, hydro-salpinx, prolapse of the uterus, and in the present case ureteral calculus were discovered. In all of these the diagnosis of appendicitis was confirmed at the operation, and although some of these complications were suspected beforehand, the majority of them had given rise to no definite symptoms, such discomforts as they may have caused being obscured by those of the appendicitis. All cases of appendicitis, with the exception of those in which there is actually acute infection present, in which the abdominal contents must be disturbed as little as possible, should be approached by the surgeon with an open mind, and he should be prepared to deal at the time, if the patient's condition permits, with such complications—that is to say, the operation for chronic appendicitis should be an exploratory one. Removal of the quiescent appendix may be as easy and safe an operation as any in surgery, and if the appendix alone be at fault, one of the most satisfactory, but unless the possibility of other conditions is considered it will often be extremely disappointing.

The patient made an uninterrupted recovery. There was a little oozing from the tube that led to the ureter, but there was no true extravasation. Otherwise the wound healed by first intention, and the patient completely lost his symptoms.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section of Obstetrics and Gynæcology.

Meeting held Thursday, February 5th, 1914.

Dr. W. S. A. Griffith in the chair.

Dr. Herbert Spencer showed a specimen of fibroma of the hymen, of the size of a pigeon's egg, removed from a woman, æt. 28, a *virgo intacta*. The tumour was a very cellular fibroma, and was ulcerated on the surface. It grew from the right half of the hymen, which formed its pedicle. Dr. Spencer knew of no record of such a case. The patient remained well after $3\frac{3}{4}$ years.

Remarks by Dr. Stevens and Mr. Clifford White.

Dr. Herbert Spencer showed a degenerated myomatous uterus resembling the pregnant organ, weighing $7\frac{3}{4}$ lbs., removed by total abdominal hysterectomy from a virgin, æt. 43. It closely resembled a pregnant uterus, which it was thought to be by experienced gynæcologists present at the operation. A section showing four myomata embedded in jelly, the

result of degeneration, further increased the similarity. Dr. Spencer pointed out the value of bulging of the lower segment (which he believed never occurred in ordinary pregnancy), and of the absence of ballottement. True ballottement he had never met with in any tumour except the pregnant uterus, but if the jelly in this case had become liquefied it is possible that ballottement might have been obtained.

Remarks by the PRESIDENT, Dr. EARDLY HOLLAND, Dr. WILLIAMSON, Dr. AMAND ROUTH, Dr. BLACKER, Dr. MAXWELL, and Professor BRIGGS.

Dr. SPENCER replied.

Dr. STEVENS read a short communication on

THREE CASES OF CÆSAREAN SECTION.

CASE 1.—Cæsarean section; labour obstructed by one half of a uterus diadelphys. Patient, æt. 20, was admitted to Queen Charlotte's Hospital on account of obstructed labour due to a pelvic tumour. This was her second pregnancy, the first having terminated normally. On examination, the head was found high up and the os three-quarters dilated. There was much œdema of the cervix. A soft tumour was felt behind the cervix bulging the posterior vaginal wall forwards below the head. It was thought to be an ovarian dermoid. It could not be pushed up. Cæsarean section was performed, and difficulty was experienced in releasing the fœtal head from the pelvic cavity. After closing the uterine incision in the ordinary way, the tumour behind the uterus was investigated, and found to be one-half of a double uterus with its Fallopian tube and round ligament complete. It was freely movable from the pregnant half. As the patient had already gone through one normal delivery it was decided to leave the double uterus alone. A complete decidual cast of the unimpregnated half of the uterus was passed on the third day. The patient did well.

CASE 2.—Eclampsia; vaginal Cæsarean section. This case occurred in a primigravida, æt. 27, in the 24th week of pregnancy. A great many fits had occurred during the day before admission to Queen Charlotte's Hospital, and during the following night. On admission the patient was quite unconscious. The urine was very scanty and loaded with albumen. The fundus uteri reached the level of the umbilicus. There were no uterine contractions, and per vaginam the cervix was long and rigid. Owing to her very serious condition rapid delivery seemed to be indicated, and vaginal Cæsarean section was performed (vaginal hysterotomy). The operation presented no difficulties, the cervix being closed by interrupted catgut sutures. The fœtus and placenta were delivered through the incision without any great trouble. The coma gradually lessened after the operation, and the patient could be roused on the day following to drink fluids. On the third morning after she was conscious and made a very good recovery. When examined on the 14th day the vaginal incision and the cervix had healed completely.

CASE 3.—Uterine fibroids, one impacted in the pelvis obstructing delivery; Cæsarean hysterectomy. The case occurred in a patient, æt. 33, married five years; no previous pregnancy. She was first seen in March, 1913, and found to have a fibroid the size of an orange low down on the posterior surface of the uterus, and others at the fundus. The cervical fibroid could not be pushed above the brim. Pregnancy had practically been prevented during the five years of her married life. As she seemed anxious to have a child, it was suggested that a normal sexual life should be led, and she became pregnant soon after April 1st, 1913. In June the uterus was definitely enlarged, and although the cervical fibroid remained fixed it was decided to let the patient go to term and undergo Cæsarean section. This was done at the Mildmay Memorial Hospital on January 8th, 1914, the uterus being eventrated to see if myomectomy was possible. It was then found that the uterus was very distorted and that the supposed cervical tumour was really in the lower part of the uterine body, the whole expansion of pregnancy having occurred at the expense of the anterior uterine wall, the posterior being occupied by the large fibroid. There were other fibroids also. Multiple myomectomy, together with Cæsarean section, seemed out of the question, as it involved many incisions and much mutilation. Supra-vaginal Cæsarean hysterectomy was therefore performed. The case did well, except for troublesome distension and vomiting of large amounts of fluid, accompanied with collapse, which occurred on the eighth and twelfth days, due to dilatation of the stomach.

Remarks by PRESIDENT, Prof. BRIGGS, Dr. HERBERT SPENCER, and Dr. BARRIS.

Dr. STEVENS replied.

Mr. GORDON LEY showed a specimen of congenital sacro-coccygeal tumour. Specimen had been removed by Mr. Preston Maxwell at the Hospital at Yung Chung, China, from the left buttock of a girl, æt. 16. It had existed since birth, and for 13 years sinuses, discharging sebaceous material, had existed in the gluteal cleft. The specimen consisted of a cyst, lined by skin, into which projected a well-formed hand with three fingers. The skin was covered by hair. In the wall of the cyst were bones, two of which resembled ribs. Accompanying the cyst was a piece of bowel opening on a skin-covered surface. In microscopical sections this resembled the recto-cutaneous junction. Mr. Ley demonstrated that the tumour was a teratoma; he stated that such a tumour might arise (1) from a primary germinal blastomere, (2) from a totipotential cell derived from post-primary blastomere. He pointed out that the inclusion of a twin save along the great longitudinal fissure was impossible, owing to the attachment of the amnion of the parent fœtus. Inasmuch, therefore, that the tumour in the case lay behind the rectum, it could not be an included twin. He suggested that the tumour probably arose from an aberrant totipotential cell or from a totipotential cell at the posterior growing point. He was of opinion that the comparative frequency of sacro-coccygeal tumours made the latter hypothesis the more probable.

UNCONTROLLABLE UTERINE HÆMORRHAGE.

Drs. H. BRIGGS and R. A. HENDRY (Liverpool) gave a report on 104 bleeding uteri after hysterectomy.

The collection of uteri from the Gynæcological Laboratory of the University of Liverpool between April, 1901, and July, 1913, was arranged in three divisions—(1) ten, aged 28 to 35; (2) eighty-one, aged 36 to 45 (delayed climacteric); (3) thirteen, aged 50 to 72 (post-climacteric hæmorrhage).

Tables were produced—(1) of the position, weights, and measurements of the uterus; (2) of the hæmorrhage, its age incidence, its mode of onset, its puerperal relation, its duration, and its relation to the thickness of the endometrium; (3) of parity; and (4) of complications.

The familiar effects of uterine hæmorrhage vary vastly from a grave secondary anæmia to an almost inappreciable invalidism or inconvenience; the corresponding resourceful management recognises a small percentage of uncontrollable uterine hæmorrhage; clinically important and pathologically attractive to the investigator.

A typical bleeding uterus was then described and shown to illustrate uncontrollable uterine hæmorrhage in the absence of an exercisable veto against "the uncontrollable"—a veto founded on the rarity of ultimate failure.

Protraction of diagnosis and treatment forcibly promoted hysterectomy.

Curettage was reviewed in its efficacy and failure in both exploration and treatment.

In non-maligant cases the limiting line against repeated curettage must somehow be drawn.

The total 40 local complications from the same or a dissimilar cause, distributed amongst 33 cases, left 71 uncomplicated cases in which the bleeding uterus reigned uninfluenced by collateral local disease.

Dr. Hendry, as Ethel Boyce Fellow in Gynæcological Pathology during the past three years, had examined the 104 uteri—3 were sacrificed to mincing in unsuccessful searches for hæmolytic lipoids; 101 were submitted to a histological inquiry in reference to (a) the musculature, (b) the fibrous tissue, (c) the elastic tissue, (d) the blood vesels, (e) the evidences of infection.

Under these headings the pathological report was

presented in detail—eighteen post-mortem uteri were examined as controls. Sparse nucleation of the muscular bundles, consistent with hypertrophy or with subinvolution, fallible as evidence of muscular degeneration, was constant in the bleeding uteri before the climacteric. Variations in the fibrous and in the elastic tissues were identical in the bleeding uteri and the controls. With the solitary exception of calcification of the media in the uterus of a 17-para, the vascular changes were also identical in the bleeding uteri and the controls. Of the bleeding uteri four showed an acute infection; and from twelve a chronic infection, either primary or secondary, could not be excluded. No abnormal histological changes could be found in the endometrium and no relation could be traced between varieties of endometrium and the duration or severity of the bleeding.

From the present available clinical and pathological evidence embodied in the report, the thesis is deducible that uncontrollable uterine hæmorrhage is a functional disturbance.

The disturbers, local and general, are numerous and varied. Amongst them, arteriosclerosis, fibrosis uteri, chronic metritis, and chronic infective endometritis have been appraised too highly and too widely within the fields of gynæcological pathology and treatment.

Remarks were made by the President, Dr. Williamson, Dr. Willett, Dr. Hendry, Dr. Handfield Jones.

Professor Briggs replied.

Section of Ophthalmology.

Meeting held Wednesday, February 4th, 1914.

The President, Sir Anderson Critchett, Bart., in the Chair.

Mr. Frank Moxon showed cases of congenital diffuse opacity of the cornea in two sisters. The children and the family had been healthy; there was no history of syphilis, tubercle or miscarriages. One of the children was ill with sickness and diarrhœa at a year old. Both Wassermann and von Pirquet reactions were negative. There was slight photophobia, but the fields of vision appeared to be normal. The cornea was milky, but there was a fairly good fundus reflex. The opaque spots were fairly evenly distributed throughout the thickness of the cornea. Lenses and vitreous were clear.

Mr. J. H. Fisher considered that the tension in all four eyes was somewhat raised, and that there was a possibility of its being a variant of congenital glaucoma; the changes were mainly in the epithelium.

Mr. Angus MacNab showed a case of nodular opacity of the cornea, which he considered bore a relation to Mr. Moxon's case. In a similar case, shown before the Ophthalmological Society, the epithelium over the nodules was somewhat heaped up. At the extreme periphery of the cornea there were loops of vessels which passed into the cornea, and that seemed to be slightly so in Mr. Moxon's case.

Mr. J. B. Lawford showed a case of brawny scleritis. The ætiology, as in all these cases, was obscure. It was an inflammatory process, with much infiltration by cells; there was nothing to suggest new growth. Every test applied to the case had turned out to be negative.

Mr. W. S. Inman showed, through Mr. Leslie Paton, a case of irido-cyclitis in a boy who had been living in Northern Nigeria, and was now suffering from trypanosomiasis Gambiense. Last October his left eye became inflamed, and three weeks ago its fellow behaved similarly. Mr. Inman had the Wassermann reaction done, and it was positive; he probably had an idea of a syphilitic origin. But Wassermann was positive in the disease afflicting the patient. There was a beautifully marked circinate rash on the front of the thigh, and enlarged, soft posterior cervical glands, from which, failing it being found in the blood, the trypanosome could generally be recovered. The Rhodesian form of the disease seemed to be more severe than the Gambian. Mr. Daniel, whom he asked about the case, said he would rather treat such a case with repeated small doses of atoxyl than with salvarsan.

Mr. Treacher Collins referred to a case of sleeping sickness which he saw with Sir Patrick Manson, and described the appearances. Eye diseases seemed to be very uncommon in connection with sleeping sickness.

Mr. Ormond showed a case for diagnosis, and Mr. Whitehead (Leeds) discussed it.

Mr. Cunningham showed a case of massive exudate in the retina.

The Section then proceeded to discuss

THE USE OF SALVARSAN IN OPHTHALMIC PRACTICE,

opened by Mr. W. Lang. He reviewed the knowledge up to date, and discussed the probable mode of action of salvarsan. During the early stages of syphilis, before the spirochætes had reached the avascular tissues, salvarsan acted readily and quickly; but later it was less efficacious, though gummata of iris, sclerotic and ciliary body seemed to be favourably influenced by the treatment. With regard to the parasyphilitic diseases, the Argyll-Robertson pupil had been once known to again react to light following intravenous injections of "606." Ophthalmoplegia externa and primary optic atrophy had not been definitely improved by the treatment. After injecting a large dose of salvarsan into a rabbit's vein, none of it was found in the cornea, though specially searched for. The usual dosage of salvarsan for the adult male was .6 of a gramme, and for the adult female .5 of a gramme; while if neo-salvarsan were used, the dose must be 50 per cent. more. The destruction of the parasites should be effected as soon as possible before they had the opportunity of becoming immune to the drug. He instanced cases in which greatly increased doses with that object had been very efficacious. Thanks largely to Mr. Browning, salvarsan was now known to be a successful treatment for sympathetic ophthalmia, and studies on the blood condition enabled one to foresee the onset of the condition.

Lieut.-Col. Gibbard, R.A.M.C., said that though salvarsan had not supplanted mercury, its action was more rapid and intense, and he narrated some striking cases illustrating this fact. Secondary lesions seemed to be more intractable than primary, and relapses were more frequent. The feature of secondary cases was the tendency to affections of the central nervous system, which was much more often involved than was formerly supposed. He did not believe this was due to salvarsan; cases were heard of more because everyone was on the lookout for untoward symptoms following the use of the new drug salvarsan. He knew of only two cases of cerebral nerve disturbance in 1,200 cases where the drug was used. And where this did occur, an increased dosage caused a disappearance of the trouble. Syphilitic meningitis was more prone to relapses, because of the inaccessibility of the subarachnoid space. Having killed off the main army of the organisms, it seemed necessary to keep in the blood a remedy which would deal with scattered survivors. At his headquarters they had given 4,000 intravenous injections, and the soldiers concerned were followed up wherever they went.

Mr. S. H. Browning read an interesting paper, in which he detailed his citological studies and the reasoning which led him to suggest giving salvarsan for sympathetic ophthalmitis. He had had excellent results in syphilis from salvarsan given per rectum. That the drug was absorbed when so given was proved by the occurrence of an arsenical rash following the method. Out of 500 to 600 cases he had not heard of a single instance of ocular palsy, optic neuritis, or other similar trouble. The most successful results from the method were in syphilitic iritis; gummata of the sclera also vanished in a marvellous manner with salvarsan and potassium iodide. He agreed with the general opinion that in interstitial keratitis it was not much good, though there had been one or two notable exceptions. His usual method was to give the drug intravenously. Neo-salvarsan was more toxic than salvarsan.

The debate will be continued at a special meeting of the Section.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, JANUARY 30TH, 1914.

The President, J. F. O'CARROLL, M.D., F.R.C.P.I., in the Chair.

JUVENILE MUSCULAR DYSTROPHY.

THE President showed a boy, aged sixteen, who, up to June last, was in good health. Going to school in that month he got several wettings and sat in his wet clothes. Towards the end of the week in which this occurred he noticed stiffness when getting up from his bench. After about three months feebleness in walking ensued. For this condition he came for treatment. No weakness was then complained of in his upper limbs. There was not much to be seen in his lower limbs. The muscles of his shoulder girdle were considerably shrunk. His wrist and fingers were stiff, but could be extended, though with some pain. The hands showed muscular failure of the palm, thumb, and little finger. There was no defect in sensation. Almost all movements could be performed, but with diminished power. It was also noticed that he had a little palatal paralysis. The case was one that suggested juvenile dystrophy, but there was nothing positive about it. The fact that the patient had slight palatal paresis pointed to the possibility of the condition being somewhat more than mere primary muscular trouble

ANTERIOR POLIOMYELITIS.

Dr. G. PEACOCKE showed a man suffering from this condition. He had been affected at the age of forty-five. The lower limbs were affected, and showed the various phenomena characteristic of the disease when fully developed.

Dr. ELLA WEBB enquired if anything was known as to the prognosis in these cases when they occurred in patients at an advanced age. In her experience of the condition occurring in young children the prognosis turned out better than the text-books would lead one to believe.

Dr. C. F. PURSER discussed the question of how long cases of anterior poliomyelitis remained infective.

FATAL ANÆMIA.

Dr. PEACOCKE read notes of a case of the above that occurred in a man aged forty-three years. His symptoms dated from February, 1913, when he suffered from pain after food, vomiting, weakness, and anæmia. Under treatment these symptoms almost entirely disappeared, but after a time returned. He first came under observation in August, 1913. His symptoms then were vomiting, with absence of HCl in stomach contents, obstinate constipation, great muscular weakness, feeble action of heart, dark pigmentation of skin of abdomen and chest, severe anæmia of a secondary type. He gradually became weaker, and died on December 2nd. His temperature was irregular, but never exceeded 100° F. No tumour could be felt in abdomen, the walls of which were markedly rigid. Heart and lungs normal. Autopsy revealed no evidence of disease.

In the absence of any malignant disease or disease of the adrenals, was this a case of pernicious anæmia, although the blood examination showed a low colour index—5—and there were no changes in the erythrocytes except some poikilocytosis?

FATALITY FROM SALVARSAN.

Dr. NESBITT reported a fatality after 0.4 grm. salvarsan intravenously in a poorly developed man of twenty-five, the subject of syphilis, either congenital or acquired early in life. Death took place twenty-five hours after the injection, which was followed by two rigors, with symptoms of collapse. At autopsy multiple gummata of the liver were found, the remaining organs being healthy. In the absence of signs of arsenical poisoning or other apparent cause of death, the theory of excessive liberation of toxin was advanced to account for the result.

Dr. H. C. EARL, in showing the pathological specimens in connection with the case, said the most striking organ was the liver, which contained numerous gummata, both large and small, of which sections were shown under the microscope. The larynx showed on the epiglottis a mucous membrane which was thickened, but not ulcerated. The kidneys appeared normal, but congested. In the upper portion of the spine the third, fourth, and fifth cervical vertebræ were necrosed. The cord and the dura mater seemed unaffected. The heart was healthy. The brain was not obtained.

Dr. MELDON said he listened with interest to the paper, as at the Lock Hospital a good number of cases were treated with salvarsan, and a great many of the patients were in a shaky condition. He suggested that the first point to be attended to was to have the alimentary canal thoroughly cleared out, as otherwise the reaction would be found to be very much greater. He would have been diffident about giving a dose of salvarsan in such a case as Dr. Nesbitt's on account of dyspnœa. In a doubtful case he thought it best first to put the patient on mercury and iodide of potash in order to destroy as many of the spirochætes as possible, and thus lessen the reaction afterwards. He considered it was rather soon to expect arsenic poisoning. He suggested that in these very bad cases the risk was well worth taking.

Dr. O'KELLY thought it was of the greatest importance that such cases should be reported. He would be suspicious of some lesion in the brain.

Dr. LILIENSTEIN (Germany) recalled the case of a patient, æt. 52, who died one hour after an injection of salvarsan, and in that case the patient showed evidence of marked arterio-sclerosis. In another case the patient developed a complete paraplegia after salvarsan, and died of pneumonia.

Mr. HENRY MOORE said *a propos* of a cerebral cause of death that it was Ehrlich's idea that all local lesions, within twelve hours after injection, swelled up enormously, and during this swelling if there was any syphilitic lesion in the brain it would cause compression and kill the patient, but he expected in this case the dangerous period from this point of view had passed. He had never seen a liver showing so many gummata.

Dr. NESBITT said he was glad to hear that it was the opinion of the members of the Section that blame did not attach to him for the administration of the drug in this case. He did not consider the patient very dyspnœic. The brain was not examined, as it did not occur to him that the patient died from nervous or brain involvement. There was no loss of consciousness, paralysis, or anything of that sort. There was no arterio-sclerosis. Although he had always used distilled water he had always experienced smart reactions.

Dr. LILIENSTEIN demonstrated to the Section his apparatus for producing phlebostasis, and detailed its uses in cardiac disease.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT at fifteenth meeting, on the 2nd inst., evidence was given by Dr. Helen Wilson.

Dr. Wilson said that it was now generally recognised that it was futile to attempt for venereal diseases such isolation as was practised in regard to acute infectious diseases, the main reason being that in a large proportion of cases venereal diseases did not prevent the sufferer from following his ordinary avocation, that they were easily concealed, and that there were strong motives for concealment. The objects to be aimed at were, firstly to bring every sufferer under treatment at the earliest possible moment, thereby shortening the infective period; and secondly to secure the patient's intelligent co-operation both for his or her own cure and for that of others. She did not think that compulsory notification would ever be a material help, but that any attempt to deal with these diseases otherwise than on voluntary lines would array a tremendous amount of opposition; if voluntary methods were given a fair and intelligent trial, she

was convinced that the residuum of cases would be comparatively small and that probably means could be found for dealing with them.

As regards the organisation of medical treatment, Dr. Wilson thought that the hard-and-fast line which has been drawn between these diseases and all others should be abolished. Admission to institutions and treatment of the diseases should not be governed by inquiries as to the method in which the disease was contracted; and the nursing and all other arrangements should be as good in the wards for the treatment of these diseases as in any others. Names like "Lock" and "Magdalene" for special wards or hospitals had a deterrent effect and should be avoided. She laid stress on the importance of providing evening clinics for out-patients.

Dr. Wilson was of opinion that further instruction was needed for medical students and nurses, and that the education of the general public in matters of sex hygiene was of the highest importance. She doubted whether it would be wise to introduce systematic class instruction in elementary schools, and she was certainly of opinion that in these schools there should be no instruction dealing with diseases.

In the first instance parents and teachers needed preparation for the work of instructing children. She understood that in some few training colleges this matter was already receiving attention and teachers were being trained, not with the object of giving class lessons, but to enable them to speak to the older children privately when they saw occasion to do so.

In some schools in America the plan had been tried of inducing the mothers to come and hear about the subject in the first place, and afterwards of beginning a course of lessons to the girls, the mothers being invited to be present the whole time.

Dr. Wilson considered this arrangement of teaching the girls in the presence of the mothers to be an admirable one as helping to secure what was most wanted, that the girls should be in the position to speak frankly to their mothers in private about the subject.

At the sixteenth meeting, Surgeon Scott, R.N., who was until recently in charge of the Naval Hospital at Chatham, gave evidence respecting the methods of treatment and results obtained in Naval Hospitals.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 21st, 1914.

Acne Rosacea—Nævi.

The treatment of rosacea is first of all dietetic—a severe alimentary *régime* must be followed. At the *début* of the affection, sulphur, salicylic acid and resorcin are the drugs that correspond to the local treatment.

Precipitated sulphur,
Zinc paste,
Vaseline (white), aa 5 dr.

To be spread on the face at night and covered with a powder composed of equal parts of oxide of zinc and starch.

More energetic is the sulphur emulsion:—

Sulphur, 2 dr.
Weak spirit, 1 oz.
Glycerine, 1 dr.

Apply with a brush at night. On washing off the next morning coat the skin with a cream:—

Lanoline, 5 dr.
Distilled water, 5 dr.
Vaseline,
Liquid paraffin,
Glycerine, aa 2 dr.

If still stronger action is required:—

Salicylic acid, 30 gr.
Resorcine, 40 gr.
Precipitated sulphur,
Zinc paste,
Vaseline, aa 5 dr.

In certain cases a cure for desquamation may be deemed necessary, but it must be used with prudence:—

Naphthol, 2 dr.
Precipitated sulphur, 1 oz.
Green sulphur, 1 oz.
Zinc paste, 4 dr.
Vaseline, 4 dr.

The paste is left on from ten to twenty minutes; the skin begins to show signs of inflammation at the end of six or eight hours.

Vascular nævi may be treated with the solid carbon pencil, but the best treatment is radium and phototherapy. Radium seems, by its soft B rays, to have a specific action on the vascular endothelium. Light acts particularly well on superficial nævi, but they may be associated. Each point is submitted for half an hour or an hour to the blue light of a quartz lamp, and at the end of a few weeks the treatment is continued by the radium.

Nocturnal Terrors in Children.

The treatment of night terrors of children formed the subject of a lecture given by Prof. Comby, the well-known specialist for children's diseases. The affection, he says, is very frequent, and throws the family into a state of alarm. The duration of the attacks being very short, antispasmodics are but of little use at the moment of the seizure. Fresh air, cold lotions, gentle words of encouragement, inhalation of smelling-salts or a few drops of ether will be found to be sufficient palliatives. To diminish the frequency and the intensity of the attacks, M. Comby advises the administration of bromides; in case of obstinate insomnia, small doses of sulfonal or trional (5 gr.) might be given in a little warm milk.

In the ætiology, besides a nervous predisposition, an exciting cause is generally found—reflex (worms, vegetations) or toxic (dyspepsia, constipation); this latter cause is the most frequent.

Nervous predisposition will be treated by warm baths given two hours at least after the evening meal. The child should be put to bed early and exciting stories or study should be avoided. A certain quantity of camphor might be placed under the bolster.

The reflex causes should receive every attention. Amongst the most frequent are worms, round and thread, vegetations, hypertrophy of the tonsils, umbilical hernia, and sometimes phimosis.

The toxic causes are still more important: auto-intoxication of the gastro-intestinal canal provoked by dilatation of the stomach and constipation; alternate diarrhœa and constipation due to enteritis is also a frequent cause. Errors in the *régime* of the child, overfeeding, coarse and indigestible food, excess of fluids, tea, coffee, should be corrected.

In conclusion, M. Comby said that too much importance could not be attached to the hygienic and medical treatment of nocturnal terrors in children, as where no distinct cause can be found fears of epilepsy in the future may be entertained.

GERMANY.

Berlin, Feb. 21st, 1914.

At the Gesellschaft der Charité Aerzte, Hr. Zerner related a case in which the findings of the Roentgen rays were of interest. The patient was a woman of 25, who had been in a clinic for some time. There was no trace of hereditary disease of any kind. The trouble for which she had been admitted was of 10 years' duration. When she was about 15 years of age she took some large bites of an apple which she could not swallow, which stuck fast a little above the stomach, and which she could only get rid of by vomiting. From that time she could no longer swallow solids and had to be satisfied with liquid and pultaceous foods. In the meantime she emaciated rapidly, and had to go into hospital in her native town. There a sound was passed, according to her own account, and for some time afterwards she could take food properly. Being so much improved she was discharged. Soon afterwards, however, the swallowing troubles returned, and she began vomiting again after trying solid food. Upon this she was advised to avoid solid food and live on soft preparations. She went into

hospital again; again a sound was passed, and again improvement took place. Six weeks after her discharge from hospital the symptoms again returned; she returned solid foods by vomiting, emaciation rapidly followed, and, according to her own statement, she had for several years entirely avoided solid foods. When she came to the Charité she was six months gravid, but she sought relief more especially for suppuration both in the bladder and kidney.

The examination was directed more especially to the œsophagus. At a distance of 42 ctm. from the level of the teeth the sound came to a resistance. At this moment the patient vomited 800 c.cm. of pultaceous matter, partly through the sound and partly round it. The mass was strongly acid, but it contained no free acid. After this an examination before the Röntgen screen was made. The metallic sound, armed with a Trousseau's knob, was passed until the knob was arrested at the cardia. The sound was seen to lie to the left of the sternum, so that there was a displacement of the œsophagus to the right. The patient was now given some barium porridge, and a watch was kept as this took its course downwards. It was seen that the porridge at first passed slowly downwards but remained fast above the diaphragm, collected there, causing the œsophagus to bulge out. Then it travelled upwards and over to the left, forming a sharp angle. After this it passed slowly downwards, and then, after passing the cardia, got into the stomach. The twisting serpentine of the lower part of the œsophagus was very characteristically shown on the three Roentgen plates, the first one taken at the time, a second a quarter of an hour later, and lastly one eight hours after swallowing the barium porridge.

For an explanation of the changes shown a congenital defect must be assumed. Such pathological spindle-shaped dentation of the œsophagus had been met with in the *post-mortem* room, but had not been observed during life, as a special study of them had not been possible until the introduction of the X-rays made the changes visible to the eye. In the lower part of the œsophagus slight dilatations were not infrequent, and they might affect either the thoracic or the abdominal portion of the organ. They had been looked on as "fore" stomachs, or cardiac antra. This became clear when the history of the development of the stomach was considered as a derivative of the "fore" bowel. Thirteen narrowings of the œsophagus had been recognised from a point of view of development, with twelve dilatations between them—one dilatation between each pair of narrowings. anomalies of form might arise from such slight dilatations. During life they gave rise to no manifestations until some external irritation, as in the case before them, an attempt to swallow lumps of apple that were too large. Besides this, as was shown on the Roentgen plate, there was atony of the œsophagus, which as was known was also congenital, a lowering of the peristaltic function, which was a "part" symptom in asthenia.

Therapeutically they were practically powerless. In the meantime they had advised the patient that when she experienced difficulty and pain after swallowing particles of food that were too large, she should lie horizontally and on her left side. It was clear that by doing this one of the turns would be straightened out. Besides this they had advised the patient to take a small dose of atropine before eating. She now says that she no longer has any trouble worth mentioning.

AUSTRIA.

Vienna, Feb. 21st, 1914.

CANCER AND RADIUM.

AT the recent Versammlung Deutscher Naturforscher und Aerzte in Vienna, Dr. G. Riehl made a communication on the subject of cancer and radium, which he prefaced with an account of the present arrangements for radium treatment in Vienna. After prolonged opposition and trouble, a radium station was at length opened in the Allgemeinen Krankenhaus in JUNE 1912. The management thereon secured a half-gramme of radium for its use, of which part was to be retained in mass, and the rest employed in production of radiations and their application. In the early part of the year, as the German clinicians at the Congress held in Halle had announced great results, the demands of the Viennese clinicians for larger quantities of radium became more pressing. The result of subsequent discussions with the management was that a gramme of radium was placed at their disposal—a quantity which was possessed by no other university. The Vienna radium station is not to be regarded as a clinical one, but it meets the demands of the whole hospital for radium. Thus it is made to serve at once the interests of suffering humanity and the progress of physical science. They give our porters sufficient instalments of radium for application per square centimetre of surface to be acted on by its radiations. In this way is provided a standard of measure of the effectiveness of the Gamma-rays. The Alpha-rays are screened off with appropriate covers. By sufficient supply and employment of effective filtering media the dosage of the radium is duly controlled.

The researches of the Klinik on the effects of large doses of radium were commenced soon after the Halle Congress, but not until the beginning of July could the newly obtained radium be applied, and its application in full dosage can be reckoned from the beginning of August only. Notwithstanding the comparative briefness of the intervening period, it now appears justifiable to adopt the results obtained in the Vienna Klinik, while the more conclusive decision of the future has, of course, still to be awaited. Here, unfortunately the old experience was repeated, that the first results of a new therapeutic agent gave rise to hopes which soon proved all too sanguine. This fact is premised as a beginning. In the treatment of cutaneous cancer platinum filters were employed, so that the Gamma-rays only should be utilised. It was found that the effect of the radiations on lupus was increased by the internal administration of iodine. No agent has yet, however, been discovered by which cancer can be made more sensitive to the effect of the radium rays. Researches on the lower animals have shown that after injection of a solution of a radium salt into the circulation the radium rays exercise a conspicuous influence on the constitution of the blood, small doses causing an increase of the proportion of white corpuscles, while large doses cause a diminution. Thus it is possible that highly intensive dosage with radium rays may lead, through general symptomatic manifestations, such as feebleness of pulse, faintness, etc., to permanent injury of the whole organism. Of the results obtained by the radium treatment of cutaneous cancer in 114 cases in the Klinik, it can be briefly stated that while the radiations were administered in small doses, the experience agreed with that of previous observers. The larger doses came into use but recently. The figures produced, and illustrated by lantern slides, showed that in cases of cutaneous cancer occurring on the face, even very large tumours could be made to shrivel by the application of small doses of radium rays—completely or partially.

The following conclusions were drawn by Dr. Riehl from the collective experience of the Vienna Klinik:—It is necessary, for comparison of the therapeutic results, that a normal standard be adopted, this to be furnished by a uniform physical characterisation of all radium preparations. The effect of radium is above all things local; even after long-continued radiations the effects which lead to the retrogression of carcinoma can be observed only in the neighbourhood of their application. Extensive carcinoma of the skin can also be influenced effectively by prolonged use of intensive radiation. A purely selective influence on cancerous tissues is afforded only by employment of massive dosage with the radium rays, as long-continued administration of strong radiations produces injury of the healthy tissues also. In cases of superficial carcinoma, as it is only its destruction that matters, a strong filtering method, such as is adopted by gynæcologists, can have but limited value, as the quantity of radiation and the time of application must both be considerably increased. Any indirect influence of the radium rays on the seat of metastases remote from the

neighbourhood exposed to the radiation—lymphatic glands, etc.—was not demonstrable.

For the application of deeply penetrating rays, and for treatment of many other skin diseases, as well as where the normal skin and other tissues require great care, strong, and more especially double, filtration is to be recommended, with filters of metal, wadding, folded paper, etc., so used as to eliminate the weak primary rays, and also the secondary ones. Patinum and aluminium filters are to be preferred, being less dangerous than the usual lead filters, which allow the weak rays to pass. With prolonged use and large quantity of the radiations necrosis results, the blood-vessels retaining their vitality longest. It must be kept in mind that there is a possibility of injuring the general constitution by prolonged use of large quantities of radium radiations. And, on the other hand, that insufficient radiation, either by use of too small a quantity of radium, or by too limited time of application, may be productive of increased rate of growth of the cancer.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Housing Reform.

Dr. A. K. Chalmers addressed a meeting in Edinburgh on February 20. under the auspices of the Charity Organisation Society, on "The Influence of the House as a Factor in the Death Rate." Dr. Chalmers said that much of the diversity of suggestions surrounding the problem of housing arose from a diversity of opinion as to the best method to reach a common objective. The legislators of the Mid-Victorian period had a clear conception of the direction which housing reform should take. Their premises were simple and the conclusions inevitable. All the substantial contributions to the administrative machinery of the last century, culminating in the Housing of the Working Classes Act, 1890, proceeded on the clear conviction that the health and morals were prejudicially affected by certain conditions of external environment which could be described. The unhealthy dwelling-house" was a house so injurious to health as to be unfit for occupation; the "unhealthy area" was a collection of such houses, including the intervening streets, courts, and alleys, if their arrangement was such as to impede light and ventilation, so as to endanger the health of the inhabitants or their neighbours. Substantial improvement was effected on these lines, but it was important to observe that all this action was taken with the single purpose of removing the inhabitant from surroundings prejudicial to health and morals. The Act made no effort to discriminate between the worthiness or unworthiness of the social groupings which were now under consideration. Substantial social reform was never wholly a question of externals. Habits were at least as important as habitations, but selective displacement was impossible even where it was desirable. Segregation by a rigid insistence on a standard of domestic cleanliness and conduct was more hopeful, he thought, but required a high standard of moral courage on the part of the local authority which put it into practice. Dr. Chalmers went on to discuss the results of a recent inquiry into the relation between housing and death-rates, and showed that as they went upwards from one, two, three, and four roomed houses they got a rapid reduction in the rate of infantile mortality.

Professor Lodge, who presided at the meeting, said that hardly any social evil was not intimately bound up with the housing problem. At present they had a Housing Commission sitting, but it was a long way from a Commission and Report to getting anything done. Commenting on the figures of Dr. Chalmers, which showed that houses affected not only the death-rate but the size, height, and weight of the children, he observed that his own belief was that heredity as a social force was a far weaker force than surroundings, and that in the course of generations the whole force of heredity could be modified by the development of the human species. They should not be discouraged from attempting to improve surroundings by feeling that they were up against the brick wall of heredity. Within his own recollection there had been a great improvement in the economic condition of the people, and therefore in their ability to pay for improved surroundings. It was on that improvement that he relied more than on any bolstering up of housing condition on an uneconomic basis, which would create a justifiable feeling of discontent among those who did not profit from this bonus of the State.

Royal Naval Medical Service.

Surgeon-General A. W. May, Director General of the Medical Department of the Navy, addressed the students of the University of Edinburgh on the advantages of the Service on February 20th. The meeting, which was held in the Union, was presided over by Sir William Turner, who remarked that although perhaps there was a stronger feeling among Scottish medical graduates in favour of the land services, they should remember that Scotland, and especially the Firth of Forth (in which it used to be a rare thing to see anything bigger than a gunboat) was fast becoming an important naval station. He thought that the time was therefore appropriate for the Director-General to tell them something about the Navy as a service which he wished to commend to them. Surgeon-General May avowed as his object in coming his desire to persuade some of his hearers to join the Service. They were short of men just now, and one of the reasons for the shortage was that the Service was judged by the conditions which existed 35 years ago, when it was not efficient. At present, however, things were entirely different. There was no finer body of medical men than existed, especially in the younger branches of the Service. Their nurses were second to none; the organisation and equipment of the hospitals were as fine as any in the world. The men they wanted were first-rate men, hard workers, and if they got those men they would be able to reward them as their work and their merits deserved.

Cameron Prize in Therapeutics.

The Senatus of the University has awarded this prize, which is given for "highly important and valuable addition to practical therapeutics," to Prof. Paul Ehrlich, in recognition of his discovery of salvarsan, of his researches on synthetic compounds of arsenic, and of his important work on immunity.

Extension of Edinburgh Post-Graduate Course.

An important addition to the summer post-graduate course will be made this year in the shape of a special course on gynæcology and obstetrics during the second half of August. This will run contemporaneously with the special course on diseases of children, which has been a feature of the post-graduate lectures during the past two years. The gynæcological course will be limited to members, and will be thoroughly practical. It should be clearly understood that these courses in no way replace the general instruction given during September, but are supplementary thereto. Post-graduate instruction is now given in Edinburgh from the middle of July to the end of September, and as about fifty of the teachers take part, it covers practically all departments of medicine. A great deal of trouble is taken by the Committee in organising the classes so that they shall clash as little as possible, and the record attendance of last year argues well for the continued prosperity of the classes.

Tropical Botany.

Mr. Montagu Drummond, B.A., F.L.S., Lecturer in Botany at Glasgow University, spent the vacation last year botanising in Jamaica. He brought home part of his collections to the Botanic Gardens, Glasgow, and he has been lecturing on his experiences. The garden where he worked is situated at Cinchona, in the Blue Mountains of Jamaica, at an altitude of 5,000 feet. The British Association has made a grant in aid of the scheme which is on foot to develop this fine centre for botanical and other scientific investigation. The garden lies, Mr. Drummond says, at one

of the most salubrious and readily-accessible spots within the tropics, and with abundance of botanical material ready to hand.

KILMARNOCK MEDICAL PANEL.

A breeze sprang up at a recent meeting of Kilmarnock Insurance Committee. A letter was read from the doctors intimating that, owing to difficulty in identifying patients in the absence of complete medical lists, the doctors would refuse, after March 15th, to attend patients who did not produce a new medical card. Provost Matthew Smith said he supposed the doctors had speculated on the position they would place themselves in by breaking their contracts and had calculated the consequences. Dr. Robertson said they only wanted to know where they stood. They were making no threat. Provost Smith: "Oh yes, you are making a deliberate threat. As soon as possible the list will be supplied, but neither the committee nor the clerk can work miracles." The clerk explained that the staff had been working overtime to get over the work laid upon them, and ultimately the matter was allowed to drop.

MEDICAL INSPECTION OF CHILDREN.

Govan Parish School Board has the largest school population under its care of all the parish school boards in Scotland, and it is therefore of interest to note how it has been getting on in the matter of medical inspection. The sixth annual report on this subject states that during the year 9,880 children were medically examined on a routine system, in addition of 13,018 examined outside of the routine system, making 22,898 medical examinations in all. It was found that approximately 11 per cent. of the children were in need of attention. The most important development during the year was the establishment of school clinics. The necessity for such provision, Dr. George Arbuckle Brown, the medical officer, pointed out, had been demonstrated by the large number of children who attended for treatment during the short period in which the clinics had been in operation. The total number of children who attended was 1,600; the two departments with the largest numbers being the eye clinic and the skin clinic. The dental clinics were also well attended.

SYPHILIS AND GENERAL PARALYSIS.

At the recent annual meeting of contributors to Glasgow Royal Asylum, Dr. Oswald, the superintendent, referred to the important discovery made since the previous meeting by Noguchi, when he demonstrated the presence of the treponema pallidum, the organism causing syphilis, actually in the nerve cells of patients dying from general paralysis. He thus proved that the disease was a syphilitic affection due to the presence of the parasites in the brain substance, and not to the toxic substances elaborated elsewhere. The drug "salvarsan," discovered by Ehrlich, and believed to be a specific cure for syphilis in its early stages, had so far had no good result when injected into the blood in cases of general paralysis; that manifestation of the syphilitic virus not appearing till many years after the original infection. The cure of that protean and inevitably fatal disease therefore depended on the prevention of syphilis or on its early cure, although possibly benefit might result in the later stages when some means were discovered of killing the parasite by bringing the drug into more actual contact with the brain substance, the local seat of the disease.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE DWINDLING FAMILY IN SCOTLAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The phenomena attending the falling birth-rate—a section of which under the above heading is so ably examined in your issue of to-day, February 18th—constitute the most sinister sign of the times. If our country is ever to fall into decadence the first indication of danger would be in a lowering of the quality and a diminution of the numbers of our people, and in a consequent curtailment of our power to occupy the limits and to develop the inexhaustible resources of the vast oversea territories under our sway. The experiment of limitation of the offspring has been carried to its logical conclusion in France. The average number of children per family does not exceed two; the deaths exceed the births; the population has been kept up during the past 30 years only by gradual assimilation of the 1,500,000 foreigners always sojourning on her soil. The effects upon the individual parents and upon their progeny have been studied by French men of science and men of letters; and the effects upon the international position of their country have been exposed over and over again by leading statesmen. M. Bertillon, whose death we have had to deplore within the last few days, had made the subject his own. The whole question was examined exhaustively by M. Desmolins in a remarkable work, a translation of which from the 10th French edition with the title "Anglo-Saxon Superiority," appeared in English some time ago. Apart from the hurtful effects upon the morals of parents, who whilst well able to support a numerous family refuse to rear more than one or two children; and apart from the injury to the character of the offspring, who, unless of the rarest innate strength of character, can hardly escape being spoilt, the narrow restriction of the birth-rate forms a gigantic system of artificial selection encouraging the production of an inferior stock and degeneration of the race. The first-born are not as a rule the best examples of the possible brood. In France these have the best chance of matrimony, whereas when the family is large those members most fitted for parentage alone find mates. These are the main facts suggested and brought out by French scientific investigators. From the point of view of the statesman, the question was handled by two distinguished ex-Prime Ministers at the Paris Hygienic Congress in May last. M. Léon Bourgeois and M. Ribot both enlarged upon the growing peril in which France stands owing to her enormous numerical inferiority to her mighty neighbour, and to the widening disparity from year to year. M. Ribot ended his speech with these words: "This country is sick and it ought to be proclaimed aloud. The French race is withering. The people must be informed of the peril by which it is menaced. All the powers of Government must be concentrated upon grappling with this peril." In face of utterances of this kind—any number similar might be cited—it is amazing to see the constant references to a French renaissance nowadays made by the British Press and public men. Their aim seems to be to support the *entente* by fulsome flattery. Human nature on one side of the Channel does not differ fundamentally from that displayed on the other; and similar causes acting upon our own people must in due course produce like effects. Whatever these effects may be with regard to the quality of our individual citizens, there can be no doubt in the question of numbers. This question has once more been gone into lately in a masterly fashion by Dr. Dudfield, and his report was summarised in *The Times* of February 3rd. If the fall in our birth-rate goes on as at present we shall in a very few years be in a position similar to that of France. We shall no longer be able to make any response to the cry for people of their own blood, more and more insistently put forth by our Colonies and Dominions—territories ten or twenty times greater than those of France and all suited to European settlers. These lands under an imperial system of emigration could take and absorb much more than our normal surplus for hundreds of years, and our surplus by extension of social reform can be bred as healthy and efficient citizens worthy to be received by kith and kin across the seas. But what has posterity done for us that we should sacrifice for posterity?

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

February 18th, 1914.

THE TREATMENT OF INFLUENZA.

To the Editor of The Medical Press and Circular.

Sir,—In your issue of January 14th, p. 28, under the heading, "Another Influenza Epidemic," the following appears:—

"Needless to say, this form of the malady is one of the most dangerous. The heart muscle is almost invariably weakened, and the sufferer runs a deadly risk if he gets up and goes about his business instead of stopping in bed and treating himself to unstinted warmth, nourishment and stimulation, the commonsense as well as the scientific tripod of influenzal nursing."

In my opinion this is a piece of very loose writing.

Treating himself.—No patient with influenza should treat himself. He would have an untrained, incompetent bungler for his doctor.

Unstinted warmth, nourishment, and stimulation.—Here one conjures up closed windows, heaped-up bedclothes, and a roaring fire, "dairy" milk, raw eggs, beef tea, etc., poured down the hapless patient's throat every three hours or so, each dose liberally fortified with brandy or whisky. Biscuits, raw fruit, etc., most likely in addition. This is putting the case mildly; worse atrocities may be perpetrated. "Dairy" milk, as found in most towns, what is it? A foul liquid not less than twenty-four hours old when delivered to the customer, teeming with germs of various kinds and laden with their toxins, coloured with anatto, fortified with fat emulsion, and preserved with crude boracic acid, an irritant poison. The thirsty patient, knowing no better probably, gulps it down as he would beer, three swallows to the half-pint.

Eggs.—How many sold in towns are less than a month old?

In influenza of all types, the gastric in particular, the poisoned brain and nervous system are working at low power. The heart, stomach and intestines are atonic and dilated. The thyroid, etc., the liver and kidneys are poisoned and feeble, yet they are called on for extra work dealing with an overwhelming torrent of virulent toxins manufactured by countless myriads of deadly influenza germs.

Fortunate is the patient who vomits incessantly under the influence of treating himself. Otherwise large lumps of putrid curd, quantities of rotten egg substance, and sour alcohol lie for hours in his capacious, almost inert stomach.

Biscuits.—It is not generally realised that these almost invariably contain fat of some kind. This in the process of manufacture becomes heated to a very high point, and so irritating chemical substances are formed.

Raw fruit.—I have seen patients laughingly eat grapes, swallowing everything, including skins and seeds, in spite of remonstrance. Bananas go down in lumps, and oranges are eaten with indiscretion also. Is it to be wondered at that under such circumstances food toxins are added to germ toxins?

So far I have assumed that the patient is treating himself. If a medical man is called in he no doubt will direct that vomit and stools be kept for his inspection. Should a patient die, a *post-mortem* examination will prove very instructive. I have seen a stomach so dilated it held over 8 pints of liquid easily. Personally, when treating influenzal patients, I do everything in my power to induce them to take nothing but sips of hot water for twenty-four hours at least. Then I cautiously introduce "things out of bottles and tins"—malted milk, meat juices, milk powder, whole or otherwise. I direct that bananas shall be mashed, oranges squeezed and only the juice taken, and so on.

I could continue indefinitely, but hesitate to take up your time. The patient's room should not be overheated, and his window should be open a few inches at the top at any rate. Two good blankets and an eiderdown quilt are quite enough bed covering. Great care should be taken during convalescence, and a premature "change of air" cannot be too strongly condemned.

I am, Sir, yours truly,

Burnemouth. W. J. Midelton.
February 21st, 1914.

[We have inserted our correspondent's pessimistic letter, but must point out that it is based on a misapprehension of the phrase "treating himself" used in the passage. "Treating" clearly does not refer to medical treatment, and, if we may say so in all courtesy, the "looseness" appears not so much in the paragraph as in the interpretation thereof.—Ed. M.P. and C.]

Medical News in Brief.

Sad Death of a Medical Student.

An adjourned inquest was held last week at the Islington Coroner's Court by Mr. Francis Danford Thomas, Deputy-Coroner for Central London, upon the body of Stanley Harold Edgar, aged 20 years, lately residing at 39, Highbury Park, a medical student, whose death took place under somewhat mysterious circumstances.

The evidence given on the former occasion was to the effect that the deceased, a medical student, was in his fourth term at the London Hospital, and was of very studious and steady habits, quiet, and reserved. He enjoyed good health up till Christmas, when he had a bilious attack. On Tuesday, the 13th ult., he was again attacked with biliousness, whilst he complained of headache. Mrs. Hobbs, the landlady, attended to him, and in the evening he appeared somewhat better. The next day he appeared as usual. On Friday, the 16th, he was again unwell, in consequence of which Mrs. Hobbs attended to him. Later on she again went to him and found him lying in bed apparently asleep. On trying to arouse him she found him lifeless.

A fellow-student at the London Hospital stated that he saw deceased on the night previous to his death and had a conversation with him. He said that he did not feel very well, but he hoped that he should be able to attend the London Hospital the next morning.

Dr. George O. Taylor, of 51 Highbury Park, stated that he had made a *post-mortem* examination, and he was uncertain from the examination of the internal organs what might be the cause of death, although it was possible he died from congestion of the lungs following an attack of influenza.

Dr. Stanley Beale, also of Highbury Park, who was also present at the *post-mortem* examination, was of opinion there was not sufficient disease to account for death, and he felt he should not be justified in giving a certificate. The stomach with its contents had been sealed for analysis.

The Coroner thereupon adjourned the inquiry to enable an analysis to be made with a view of ascertaining, if possible, the exact cause of death.

On the case being resumed, Dr. Ludwig Freiberger, toxologist to the London County Council, stated that he had made an analysis of the contents of the stomach and internal organs, and found no trace whatever of poison. In his opinion death was due to asphyxia from an acute attack of pneumonia.

The jury returned a verdict of "Death from natural causes."

Addition to the Alton Cripples' Hospital.

The foundation-stone of a nurses' home in connection with the Cripples' Hospital at Alton, Hants, was laid by Lord Northbrook last week, when Sir William Treloar read the following message from Queen Alexandra:—"I offer to Lord and Lady Northbrook and to you my sincere congratulations upon the interesting ceremonies which take place at Alton to-day. I am very glad to hear of the progress of the Queen Alexandra Nurses' Home, which will add so much to the comfort of the nurses and also enlarge the scope of the work at Alton. I wish continued success to your work on behalf of poor crippled children." A visit was afterwards paid to the Hampshire ward of the hospital, where Lady Northbrook unveiled a tablet recording that it was so named in recognition of the assistance given to the hospital by the residents of the county.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

The Disinfection of Typhoid Stools.—Linenthal and Jones (*Boston Med. and Surg. Jnl.*, January 8th, 1914) discuss the important matter of the best method of disinfecting the excreta of patients with enteric fever. The bedside disinfection of such stools is by no means easy, and Dotty, who made an investigation of the various disinfectants recommended, came to the conclusion that after twenty-four hours' exposure to the disinfectant only one-eighth of an inch of the fæcal mass was disinfected. Heat, either by boiling water or steam, was the only effective way of dealing with typhoid discharges, and the apparatus needed for such disinfection is not as a rule available in the ordinary household. In 1912 Kaiser suggested an alternative method which should be both practical and effective, and only requires such utensils as are available in every household. The method consists in adding enough hot water to cover the stool in the receptacle, and then adding about one-fourth of the entire bulk of quick lime (calcium oxide), covering the receptacle and allowing it to stand for two hours. The hydration of the lime generated sufficient heat to destroy the typhoid organisms. The authors have undertaken experiments to test the efficacy of this method. An ordinary tin pail with a loose-fitting cover was used, and to a litre of cold water were added from 300 to 400 grams of ordinary quick lime. Observations showed that the temperature developed varied a good deal, apparently due to the quality of the lime used. In some cases the temperature would rise to 80° or 90° C. in ten minutes, in other cases half an hour passed before the temperature reached 75° C., while in several experiments the temperature did not rise above 55° C. If, however, hot water (50° to 65° C.) was used, the temperature invariably rose to 75° C. or over in ten minutes, and in twenty minutes it reached 85° and often 90° C., and the temperature remained over 60° C. for an hour and a half or longer. It was found that the temperature was maintained for a longer period when an earthen vessel was used than when a tin vessel was used. Further experiments were made to discover whether the heat generated was sufficiently penetrating to destroy the organisms in the centre of the fæcal mass. Capillary glass tubes were buried in the centre of the fæcal masses, and the typhoid organisms contained in these tubes were found to be killed at the end of one and a half hours. The writers conclude that in this we have a simple and efficacious method of disinfection, and one that should take the place of the various methods recommended by local boards of health. K.

Mortality of Hereditary Syphilis.—Post (*Boston Med. and Surg Jnl.*, January 22nd, 1914) analyses the mortality among thirty syphilitic families whose histories have been obtained at the Boston Dispensary Clinic. In these 30 families there have been 168 pregnancies, of which 53 resulted either in still-birth or miscarriage, and 44 in the early death of the infants born alive. In other words, 97, or 57 per cent., of the offspring were lost, and out of the 115 children brought living into the world only 71 remain alive. Of these 71 children 32 have been treated in the Dispensary Clinic for disease attributable to the syphilitic poison. It will thus be seen that out of 168 pregnancies in these 30 families only 39 children can be presumed healthy. Fournier has given a similar table for 500 syphilitic families with whose history he was acquainted. In 223 of these families no transmission of the disease had taken place, but in 277 families there had been such transmission. In these 500 families 1,127 pregnancies had occurred, from which 600 children are reported living and well. Of the 527 remaining, or 46 per cent., the result has been unfortunate. There were 230 abortions and still-births, 245 early deaths, 38 living syphilitics, and 14 mentally deficient children. Such results justify Post's conclusion that "probably no other disease presents the same sad history as syphilis." K.

Serum Reaction in Pregnancy and Cancer by the Coagulation Method.—Kisig (*Jnl. Obs. and Gyn. Brit. Emp.*, xxiv., 6) says that it is too early to make any precise statements as to the clinical value of the test; he believes that it will prove a useful adjunct to the diagnosis of doubtful pregnancies, ectopic gestations, and missed abortions, and may be useful in the early recognition of chorion-epithelioma following vesicular mole. Carcinoma and sarcoma may be diagnosed, though so far they cannot be differentiated from pregnancy. The test is positive all through pregnancy, but may be negative in the presence of severe infection. With certain limitations, it is possible to diagnose carcinoma and sarcoma, but not to differentiate them from pregnancy, because the ferments are not absolutely specific. There are three methods for the test—an optical method, a dialysation method, and a coagulation method. The last is the one dealt with, and is said to be most useful, as it is less complicated, avoids error in instruments, and is not so susceptible to slight hæmolysis. It requires a longer time. F.

Serology of Pregnancy and Cancer.—Schwarz (*Amer. Jnl. Obs.*, lxix., 1), in a long paper describes the methods of making the different tests, and discusses the probable diagnostic value in the different conditions. In pregnancy a positive reaction indicates that the body contains placental tissue or has done so within ten weeks. The test is obtainable from the sixth week of pregnancy to two weeks after the expulsion of the ovum. It may therefore be of value in the diagnosis of pregnancies of any kind, and in conditions arising from pregnancy such as chorion epithelioma. A negative diagnosis means that the body no longer harbours living placental tissue; thus, a hæmatocele from a tubal pregnancy may contain dead placenta, but give a negative result. In the case of toxæmias of pregnancy, the power of the body serum is greatly diminished or absent, and the method may be used as a diagnostic aid in these conditions. When the results obtained are feeble, the prognosis is better than when absent, and the intensity of the toxæmia may be gauged by this method. The possibility of treating toxæmias by the introduction of normal pregnancy sera is considered. The method is also suggested as a means of telling the condition of cases operated upon for malignant disease and in the diagnosis of cure or relapse after radical operations. F.

Cæsarean Section.—Davis (*Amer. Jnl. Obs.*, lxviii., 6) reports a consecutive series of 193 operations. The results show 90.2 per cent. recovered, and 19 cases died. Only four deaths occurred among the last 93, and three of them were from sepsis. The author is a strong advocate for the operation, chiefly in cases of contracted pelvis, but also in many other conditions, and the series contains cases operated upon for accidental hæmorrhage, impacted face, after ventral suspension, tonic uterine contractions, placenta prævia, eclampsia, prolapse of the cord, neoplasms obstructing labour, and atresia of the vagina. Contracted pelvis was found in 81 per cent. of the cases, and in many of the other conditions operated for it was a further indication. Five cases were operated upon with placenta prævia, but three of these had contracted pelves. Fifteen patients were operated on for eclampsia, all of whom were either having convulsions or in coma, and none were in labour. Eleven mothers recovered, the mortality being 26.7 per cent. Eleven children lived out of 17 delivered, the mor-

tality being 35·3 per cent. In four cases of tonic uterine contraction three mothers recovered, but no child was born alive. In the cases of prolapse of the cord one was a case of twins. All the mothers and children lived, and there is no evidence that there was any pelvic contraction. Those cases in which there was pelvic contraction are outside criticism, as the degrees of contraction are not given, but some of the other conditions treated as indications for Cæsarean section will not meet with general acceptance. The results reported do not seem to be such as to recommend the practice. The author holds, too, that once Cæsarean section has been done, it should always be done in the same patient. Three cases had subsequent rupture of the uterus during pregnancy, two through the scar, and one of these proved fatal. The patients are recommended to be kept under close observation of a nurse or in hospital during the last weeks of subsequent pregnancies, and to be operated upon before the onset of labour. F.

Thyroid-tissue Tumours of the Ovary.—Outerbridge (*Amer. Jnl. Obs.*, lxviii., 6) considers this form of tumour and reports a specimen almost wholly composed of thyroid tissue. He concludes that in certain ovarian tumours there occurs tissue which cannot be distinguished from the thyroid gland. Between tumours which show a complex teratomatous structure containing, among other elements, a small amount of thyroid tissue, and those composed solely of this, there is no division, all being of similar genesis. The large majority are benign, and give rise to no symptom other than those concomitant with tumours of equal size. The thyroid tissue in the ovary is of no functional significance. F.

Methods of Treating the Appendix Stump.—Henderson (*Brit. Med. Jnl.*, January 31st, 1914), reports two cases where the proximal end of the appendix could not be removed. In the first case the freed part of the appendix was tied off, the base was "squeezed" by forceps to obliterate communication with the cæcum, and the still adherent proximal portion crushed longitudinally to destroy its vitality. The cæcum was brought up to the abdominal wound and secured by a few points of suture. The "dead" appendix was now extra-peritoneal, and it was further isolated by ribbon gauze. The usual drainage was employed, with closure of the rest of the incision. In the second case the appendix was adherent to the ileum, so that the ileum and cæcum were secured in the wound and the appendix isolated in the abdominal incision. In a third case an inflammatory mass as large as a child's fist, without abscess formation, was found. The appendix was at first retrocæcal, and then passed upwards and outwards, embedded on the outer wall of the cæcum. The cæcum itself was glued to the posterior parietes, and was absolutely immobile. The distal half of the appendix lying on the outer cæcal wall was easily separated, but not so the proximal half. The distal end of the appendix was cut off without ligature, a small stab hole made into the lumen of the cæcum through its outer wall, and the open end of the appendix stump thrust through into the cæcum, and secured by two or three points of catgut. The appendix stump now opened into the cæcum at both ends, and the wound was closed without drainage. All three cases made good recoveries. S.

Operative Treatment of Paralytic Talipes, Calcaneus, and Allied Distortions.—Royal Whitman (*Med. Record*, January 10th, 1914) points out that as the astragalus is the centre of all movements of the foot, it follows that in deformities it is also the centre of all distortions. The most important of all forms of deformities is calcaneus, because paralysis of the calf muscles induces a deformity that progresses in spite of mechanical restraint. The removal of the astragalus is an essential preliminary to permanent relief. The laxity of tissues thus obtained enables one to displace the foot backwards, and to implant the malleoli on its basic structure near the centre. This equalises the leverage and checks dorsal flexion by direct impact of the tibia with the scaphoid. Tendon transplantation of the peronei restores some power of the plantar flexion. Arthrodesis of the ankle is the only operation that need be seriously considered in comparison, but its range is limited, as ankylosis is impracticable till late childhood. In arthrodesis as the foot is fixed at right angles, or oftener in slight dorsiflexion, and therefore in shortening, an unsightly cork sole must be worn in contrast with a high heel or even an extension shoe. But removal of the astragalus does not materially shorten the limb. The operation is of service in paralytic talipes associated with lateral instability as equino-valgus in flail foot, in cases of complete paralysis of the extremity in older patients when combined with arthrodesis of the knee. It is useful for tuberculosis of the ankle, in which one aims at removing the disease and yet retaining motion, to restore motion at the ankle in cases of ankylosis, or of deformity and limited movement caused by fracture of the astragalus or of the malleoli. In all cases the foot must be displaced backwards, but in the last two cases not to such a degree as to check dorsal flexion. The operation is performed through an incision encircling the back and lower end of the external malleolus. After division of the peronei the foot is adducted and the astragulus removed. A thin section of bone is cut from the adjoining surfaces of the cuboid and os calcis. On the inner side a pocket is formed by an elevator at the inner border of the scaphoid. The malleoli are shaped to fit the new articulation. The peronei, freed from the lower end of the fibula, are passed through and sewn firmly to the base of the tendo Achillis, and then drawn forward and united to their distal extremities. The foot is now displaced backwards, the external malleolus overlapping the calcaneo-cuboid articulation, the internal the navicular bone. The wound is closed without drainage and the foot fixed in plaster in moderate plantar flexion and abduction. The patient walks in plaster in three to four weeks, and in four to six months the joint becomes stable, and a suitable shoe can be worn. S.

The Functions of the Colon, with Special Reference to the Movement of Enemata.—Drummond (*Brit. Med. Jnl.*, January 31st, 1914) conducted his investigations in patients with fæcal fistulæ, and by X-ray examinations after bismuth and barium enemata. One and a half to two pints injected per rectum invariably reach the cæcum, but rarely any further in normal cases, and when they do pass the ileo-cæcal valve there is, as a rule, some pathological condition present. The fluid was injected slowly and rhythmically by means of Higginson's syringe. Where there was no obstruction of the large bowel the enema reached the cæcum in ten minutes or under. The passage of fluid is likely to be retarded at the junction of the rectum and pelvic colon and at the splenic flexure. In recent cases of ileo-colostomy (division of the lower end of the ileum and transplantation of the proximal end into the pelvic colon low down), the writer found that fluid travelled up the large intestine, but there was no indication that it entered the small bowel. After a year or so, however, the fluid ran up into the small bowel, and was seen to distend the ileum, lying to the right side of the abdomen, and it was not till a considerable amount of fluid was so disposed that the large intestine proximal to the anastomosis began to show a shadow. This seems to show that the dilated coils of small intestine adjacent to the colon assume to some extent the function of the large gut. S.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

PERSIMMON.—The term "albumen" is now confined to describe the chief constituent of the white of egg; "albumin" to this

constituent when found to exist elsewhere, such as in the albuminous bodies, inclusive of all substances having a general resemblance to albumen.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to your kind notice in to-day's issue of the MEDICAL PRESS AND CIRCULAR, of the Arnott Medal, I would like to point out that the Medal is presented annually by Mr. Arnott, of the *Irish Times*, in memory of his father (the selection is made by our Association).

Yours faithfully,

SHEPHERD BOYD.
Hon. Prov. Sec.

Harrogate, February 18th.

DR. P. R. (Hants).—The Binet-Simon tests are of considerable value in marking the development of a child's mind, though they are less suitable for measuring the degree of intelligence. Whipple's work is more intimately concerned with finding out the range of information by certain mental tests.

PARIS, LYONS AND MEDITERRANEAN RAILWAY.—ROME.—EASTER, 1914.

On the occasion of the Holy Week in Rome, the Continental and English railway companies have arranged to issue, by specified trains, on April 2nd and 9th, cheap tickets for independent travel, available 33 days from London; the highest return fare from London to Rome, via the Mont Cenis route, is £10 4s. 9d., first class, and the lowest is £4 13s. 2d., third class. The Riviera route can be chosen at a slightly increased cost. For full particulars apply 179 Piccadilly, London, W.

ONERUS.—Lactose, in appreciable quantity, may occasionally be found in the urine of nursing women.

ROYAL MEDICAL BENEVOLENT FUND.

A GENERAL Meeting of the Fund will be held at the rooms of the Medical Society of London, 11 Chandos Street, Cavendish Square, W., on Thursday, February 26th, at 5 o'clock. The Annual Report will be read and certain formal business transacted. There will be *no speeches*, but *Tea* will be provided. It is hoped that as many possible of those interested in the work of the Fund and its Guild will take the opportunity of meeting together.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 25TH.

BRITISH OTO-LARYNGOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square, W.).—4 p.m.: Exhibition of Cases.

HUNTERIAN SOCIETY (Guy's Hospital, London Bridge, S.E.).—4 p.m.: Clinical Afternoon. Dr. Iredell: Demonstration of Diathermy and the Results of the Treatment in Certain Cases.—Mr. J. G. Saner: Cases of Ileo-sigmoidostomy and Colectomy Operated on between January and June, 1910 (with Sir Arbuthnot Lane's kind permission).—Dr. Hunt: Demonstration of the Electro-cardiograph.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lectures:—Prof. A. Keith: Evolution and Diseases of the Anthropoid Apes; Lecture IV., Injuries and Diseases of Anthropoid Apes; Lecture V., Structural Changes Due to Age, Sex, and other Conditions; Lecture VI., A Résumé of the Present State of Knowledge regarding the Various Forms of Extinct Anthropoids. (Illustrated by specimens from the Museum of the College; the epidiascope will also be used.)

THURSDAY, FEBRUARY 26TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY, SECTION OF OPHTHALMOLOGY, SECTION OF OTOLOGY) (Combined Meeting) (1 Wimpole Street, W.).—8 p.m.: Cases and Demonstration: Physiological and Pathological Nystagmus of Labyrinthine Origin. 9 p.m.: Discussion: On Nystagmus (to be opened by Mr. Holmes Spicer, Dr. James Taylor, and Mr. Sydney Scott). The discussion will be continued on Wednesday, March 4th, at 8.30 p.m., when Dr. Llewellyn, Dr. Dan McKenzie, and others will take part in it.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Dockrell: The Solution of the Confusion between Pityriasis Rubra Pilaris and Lichen, and the Treatment of Each.

FRIDAY, FEBRUARY 27TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Dr. F. G. Crookshank, Dr. J. F. O'Malley, Mr. W. Girling Ball, Mr. W. Barrington Ward, Dr. Edmund Cautley, Dr. Longmead, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF EPIDEMIOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Lecture: Sir Ronald Ross, K.C.B., F.R.S.: Malaria in Cyprus and Greece.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lectures:—Prof. A. Keith: Evolution and Diseases of the Anthropoid Apes; Lecture IV., Injuries and Diseases of Anthropoid Apes; Lecture V., Structural Changes Due to Age, Sex, and other Conditions; Lecture VI., A Résumé of the Present State of Knowledge regarding the Various Forms of Extinct Anthropoids. (Illustrated by specimens from the Museum of the College; the epidiascope will also be used.)

MONDAY, MARCH 2ND.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Arris and Gale Lecture by Professor David Waterston, M.A., M.D., F.R.C.S.Ed., on "The Development of the Heart in Man in Relation to its Functional Activity."

TUESDAY, MARCH 3RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY: SUB-SECTION OF ORTHOPÆDICS).—4.30 p.m.: Cases by Mr. J. E. H. Roberts, Mr. Max Page, Mr. A. S. Blundell Bankart, and Mr. Laming Evans.

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY) (Lister Institute, Chelsea Gardens, S.W.).—8.30 p.m.: Laboratory Meeting. Dr. Penfold: The Agglutination of Red Cells by Bacteria. Dr. Sherwin: Complement-fixation Reactions in Ecampsia. Dr. Dalyell: The Isolation of Certain Intestinal Anaerobes in Pure Culture. Dr. Ledingham: A Problem in Bacterial Variation. Dr. Arkwright: Observations on Cat-Distemper (so-called Show-Fever). Dr. Schutze: Cataphoresis Experiments with Leucocytes.

Appointments.

COLE, SYDNEY JOHN, M.D., B.Ch.Oxon., Medical Superintendent of the Wilts County Asylum, Devizes.

JOLL, C. A., F.R.C.S.Eng., Assistant Surgeon to the Royal Free Hospital.

MCKEE, SAMUEL KENNY, M.B., B.Ch., B.A.O.Belf., D.P.H., Assistant Medical Officer of Health of Exeter.

PARRY, L. A., M.D., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to Sussex Eye Hospital, Brighton.

PERMEWAN, WILLIAM, M.D.Lond., F.R.C.S.Eng., Lecturer in Laryngology in the University of Liverpool.

SHAW, J. R., M.B., Ch.B.Glasg., Assistant School Medical Officer for Cheshire.

TWIST, N. S., M.B., Ch.B.Leeds, Poor-law Medical Officer for Normanton District, and Public Vaccinator for Normanton and Altofts District of the Wakefield Union.

Vacancies.

Manchester Royal Infirmary and Dispensary.—Appointment of two Honorary Assistant Physicians, two Honorary Assistant Surgeons, and an Honorary Dental Surgeon. Applications to Walter C. Carnt, General Superintendent and Secretary. (See advert.)

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Ballymore Eustace (Kildare), Fleetwood (Lancs.), Keyingham (Yorks.), Trowbridge (Wilts), Uttoxeter (Staffs), Crediton (Devon), Knaresborough (Yorks), Ongar (Essex).

University of Leeds.—Demonstrator in Bacteriology. Salary £250 per annum. Applications to the Secretary, Dean of Medicine.

Caterham Asylum, Caterham, Surrey.—Senior Assistant Medical Officer. Salary £300 per annum, with board, lodging, and washing. Applications to the Clerk of the Metropolitan Asluyms Board, Embankment, E.C.

Brentwood Asylum, Brentwood Essex.—Assistant Medical Officer. Salary £200 per annum, with board, attendance, lodging, and washing. Applications to the Medical Superintendent.

City of Birmingham.—Assistant Medical Officer to the Yardley Road Sanatorium and Anti-Tuberculosis Centre, Broad Street. Salary £250 per annum, board and residence. Applications to the Medical Superintendent, Yardley Road, Birmingham.

Births.

COOPER.—On February 18th, at Lansdowne, Hampton, Middlesex, the wife of Harold Merriman Cooper, M.B., of a daughter.

COSTELLO.—On February 9th, at 28 Woodstock Avenue, Hendon, the wife of Charles Costello, M.D., West African Medical Staff—a son.

PRINGLE.—On February 11th, at 153 Withington Road, Whalley Range, to Dr. and Mrs. John Pringle—a son.

RUTHERFORD.—On February 18, at Glenbervie Cottage, Little Kingshill, Great Missenden, Bucks, the wife of Captain T. C. Rutherford, Indian Medical Service, of twins—girl and boy (Elizabeth Alison and Thomas Nichol respectively).

Marriages.

FROST—RAWLINS.—On January 15th, at St. Luke's Church, Jullundur, India, Lieutenant-Colonel G. H. Frost, I.M.S., 4th Gurkhas, son of the late John Frost, Esq., Ennis, Co. Clare, to Sara, daughter of the late Major-General J. S. Rawlins, sometime Commandant, 1st Gurkhas.

MCDOUALL—GARRETT.—On February 18th, at St. Michael's Church, Highgate, John Crichton Stuart McDouall, of the West African Medical Staff, eldest son of Willoughby Crichton McDouall and Mrs. McDouall, of Omaru, New Zealand, to Marguerite Lavina (Madge), second daughter of Mr. and Mrs. Frank Garrett, of "Red Bank," Hornsey Lane, Highgate.

RALPH.—YELF.—On February 14th, at St. John's, Notting Hill, W., Dr. C. H. D. Ralph, West African Medical Staff, eldest son of the late Colonel Ralph and Mrs. Ralph, Canford Cliffs, to Marcia Frederica, daughter of the late Dr Yelf, Moreton-in-Marsh, Glos., and Mrs. Yelf, Kensington. W.

SIDGWICK—MILLER.—On February 17th, at the Parish Church, Wimbledon, Capt. H. C. Sidgwick, R.A.M.C., to Marjorie Molyneux, only daughter of the late Robert Miller, of Wimbledon.

Deaths.

ATKINSON.—On February 11th, at Grimsby, Frederick Horatio Atkinson, L.F.P.S.Glasg. and L.M., aged 75.

BRYCE.—On February 21st, at 34 Greenhill Gardens, Edinburgh, William Bryce, M.D., in his 93rd year.

FENOULHET.—On February 16th, at Durban Hospital, Natal, S. Africa, Dr. James Peter Fenoulhet.

GARDNER.—On February 15th, at 276 Earl's Court Road, London, John Twiname Gardner, M.R.C.S., L.R.C.P., late of Ilfracombe, aged 59.

GOODCHILD.—On February 16th, at Bath, John Arthur Goodchild, Surgeon, formerly of Bordighera. aged 62.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, MARCH 4, 1914. No. 9.

NOTES AND COMMENTS.

The Normyl Treatment for Inebriety.

IN the correspondence columns of our present issue appears a letter from the well-known London magistrate, Mr. Cecil Chapman, with regard to the Normyl treatment for inebriety. Some of our readers will perhaps recall a letter that appeared in our issue of February 11th suggesting that the Normyl Treatment Association had apparently come to an end. A vigorous answer was sent by Mr. Cecil Chapman, but, owing to its length and to the pressure on space, it was unavoidably held over until the following week. As it appears that the Association is still alive, we regret that any misapprehension on that score should have entered our correspondent's mind when he sent the initial letter. As the matter of so-called cures for drunkenness is one of great importance to the community, we have thought it well to inquire somewhat more closely into the Normyl Association. Some years ago the claims of the Normyl Association were discussed in these columns. It was then pointed out that the basis of the treatment was a secret medicine, and an investigation by scientific experts was asked for. It was settled to discuss the terms of investigation at an interview. The representative of a London newspaper attended, but the medical man who was to attend on their behalf failed to put in an appearance, and the whole thing fell through.

Normyl, Limited.

YEARS later we find ourselves faced with much the same state of affairs. A small knot of philanthropists, whose motives are transparently pure and simple-minded, are still doing their best to persuade the public of the virtues of the Normyl Treatment as a cure for drunkenness. *Primâ facie* it is scientifically impossible to conceive that an abnormality of moral control, such as that evidenced in inebriety, could be prevented or removed by the administration of any drug or combination of drugs. The worthy gentlemen, however, who have formed themselves into a limited company for the purpose of promoting the use of the Hutton-Davis antidote, have no doubts as to its efficacy. If that premise be assumed, then we find no difficulty in accepting the eloquent peroration of Mr. Cecil Chapman's letter. Were inebriety to be "cured" off-hand by the simple administration of Normyl treatment at three guineas a course, then any man who belittled it or denied it to his fellows would be a traitor to humanity. But is the efficacy of Normyl proved, say, in such a way that it would be endorsed by one of our great scientific physicians? Short of complete scientific proof of that kind, one can but admire the moral courage that leads laymen into the responsibility of forming a limited company to advance the interests of a secret remedy. The fact that the company is not a dividend-making one does not materially lessen the responsibility of the directors. The whole matter is one of such social and professional interest, that we propose dealing with it in a series of leading articles, the first of which will be published next week.

Miss Pankhurst on Venereal Diseases.

BY some phantasy of intellectual process, Miss Christabel Pankhurst has drifted from militant politics into a sort of militant pseudo-science. She has acquired just enough smattering of medical matters to talk glibly about the facts of venereal disease. The connection between political suffrage and the prevention of venereal disease is no more than that which may be traced in almost every salient fact of the daily life of the citizen. The conferring of the Parliamentary vote upon women is hardly likely to lessen the incidence of venereal disease upon the community. With a better knowledge of disease, medical science may achieve a vast deal towards the stamping out of these maladies before another generation has come and gone. Parliament may also help materially by providing free diagnosis and treatment for all classes of the community, notably for the panel doctors, and by endowing the voluntary medical charities. All such work, however, could be effected just as well, if not better, by a male as by a female electorate. Miss Pankhurst's literary style deals in superlatives, and rushes into extremes. Her assumption that men are mainly responsible for the spread of syphilis is untenable. In what way would the conferring of the female franchise prevent immoral women from becoming centres of infection? It is all very well for her to write: "The moral of it all is, as we Suffragettes have so repeatedly maintained, that the real cure of syphilis is prevention." That profound proposition has a wide application to many maladies, quite apart from votes for women. Medical men would rather say the real cure of syphilis is effected by salvarsan, mercury, and the iodides, and that it is simply a confusion of thought that seeks to "cure" a disease by preventing what does not exist.

Syphilophobia.

How is the disease to be prevented? Apparently by moral means, in some way or other depending on the Parliamentary votes of women. We have it recorded in history how the C.D. Acts were repealed, and in that way defeated the only practical legislative measure that ever attempted to deal with the subject. The suggestion of a medical

certificate of freedom from venereal disease in the case of intending spouses affords a sound precaution, and as such was strongly advocated before the recent Divorce Commission. As to the claim that no one who has suffered from venereal disease, or has been exposed to the risks of contracting the same, should thereafter marry, such a proposal, if applied at all extensively, would mean the rapid extinction of the nation. Miss Pankhurst quotes Brieux to the effect that only about four per 1,000 males have not run that risk. She herself places the percentage of men affected with syphilis at a high figure. Only a week ago the present writer interviewed a taxi-driver who came to hospital suffering from a mild attack of *acne vulgaris*. He quoted Miss Pankhurst as an authority for the statement that 95 per cent. of men had syphilis, many or most of them without knowing it, and asked that his blood might be tested. In order to quiet his mind this was done. It is difficult to see what good extreme statements of the kind quoted can do to society, and still less how they can possibly advance the cause of woman's suffrage, which, as a matter of fact, has a good and sufficient foundation of its own, as most thinking men will readily acknowledge.

The Diagnosis of Phthisis.

THE difficulties in the diagnosis of phthisis are well known. In the earliest stages it may pass as anæmia or simple debility, while when the disease is more fully developed, it may be taken for bronchitis. A history of hæmoptysis, night-sweating, or wasting would, of course, arouse suspicion, and lead to a more thorough examination. The matter was raised at a recent inquest held at the Shoreditch Coroner's Court upon the body of a Hoxton boot-finisher, who died in the Shoreditch Infirmary. In the course of his evidence, the son of the deceased stated that he thought his father was suffering from tuberculosis, and he complained that a panel doctor, under whose care he had been for five weeks, had diagnosed the condition as bronchitis. Not being satisfied, he took his father to the infirmary, where he was examined and admitted, but succumbed the following morning. The medical superintendent of the infirmary stated that the man showed signs of phthisis of both lungs upon admission, and on examination there were cavities found at both apices. The man was much emaciated, and evidently in a state of rapid consumption. Another medical man was said to have given a certificate that the deceased was suffering from influenza. The coroner remarked that the true condition was evidently not realised by the two medical men, and that all were liable to err, but that he did not think there had been any neglect shown in the case. A verdict of "Death from natural causes" was returned. Such a case as this emphasises the importance of a very careful physical examination, supplemented where necessary by the X-rays, or even a tuberculin test, in all doubtful cases of bronchitis.

Herbalists under the Act.

AN important memorandum was presented to the National Insurance Act Committee and Executive of the General Medical Council on February 23rd by the President, Sir Donald MacAlister. It dealt with the position of medically unqualified persons under the Act, and also with a correspondence between the Council and Sir Robert Morant, Chairman of the National Health Insurance Commissioners with regard to the situation created by one or more Local Committees which had sanctioned payment for medical treatment by unqualified persons (the notorious herbalist's case). Sir Robert referred in correspondence to the fact that while the Bill was in the Commons it had been explained that it was left to the discretion of Local Committees under certain conditions to grant payments for such services. No mention was made of that provision in the 1913 regulations, but it had been expressly forbidden by those of 1914. This happy result seems to have been largely due to the firmness and promptitude of the General Medical Council. The view has always been taken in these columns that the Council might if constituted on a fresh basis adequately representative of the whole profession as well as of certain favoured corporations, play a great part in the future of medicine instead of specialising on the *Register* and on medical qualification. On the present occasion, however, the Council deserves the hearty thanks of the profession for the way in which it has checkmated the herbalists.

"The Pains of Death."

AN interesting correspondence has lately taken place in the *Times* upon the question as to whether the last stages of existence, or what may be termed the death agony, are accompanied by physical pain. Professor J. Cook Wilson described the terrible respiratory struggles of his father when dying from cardiac failure following influenza, which were so harrowing to witness. At the time he (the professor) was assured by the medical men in attendance that his father was not really suffering pain, and that he knew nothing of his condition. His father, being of a strong constitution, survived the night, and was able to testify the next morning that he had passed a comfortable night, thus corroborating the medical opinion. In a second experience of the kind, Professor Wilson observed that the panting was less violent, though there was no recovery; but it was an inexpressible relief to him to know that the physical struggle for breath was unconscious. Another correspondent recalled the fact that when he lay dying, as his friends thought, of typhoid in a Mexican mining camp, he was entirely free from pain, fear, or anxiety, though he was informed that in his delirium he was screaming and fighting as though suffering agony. Sir Henry Morris follows in a scholarly communication respecting the painlessness of most cases of death which appear so distressing to watch because giving the idea of pain, and offering at the same time some practical suggestions for the relief of the stertor. Euthanasia is largely a question of posture, a fact known to every skilled nurse. It is just as well that the fact should be known that the act of "shuffling off this mortal coil" is not necessarily—nor, indeed, usually—accompanied by mortal pains.

Oxford Ophthalmological Congress.

UNDER the presidency of Mr. Robert Doyne, and the vice-presidency of Sir Anderson Critchett, the next meeting of this important Congress will take place at Keble College, Oxford, on July 8th to 10th. A discussion, to be opened by Mr. William Robinson, F.R.C.S., of Sunderland, will take place upon "Workmen's Compensation in Injuries of the Eye," which seems a good practical subject for expert consideration. Specimens, etc., are needed, and, needless to say, will be welcome. Among distinguished visitors who have announced their intention of being present at the Congress are Dr. Darier, of Paris, Professor Deutschmann, of Ham-

burg, Dr. Casey A. Wood, of Chicago, and Dr. Wendell Reber, of Philadelphia. Further details as to this most interesting meeting may be obtained from the Hon. Secretary, Mr. Sydney Stephenson, Welbeck Street, London, W.

LEADING ARTICLES.

TRANSATLANTIC JOURNALISM AND THE MEDICAL PROFESSION.

"Other times other manners" is a saw eminently true of journalism, the evolution of which imports fresh methods that are in some instances not a little disconcerting to established usage. During the past generation the public press of the United Kingdom has been invaded by a callous and lying cynical spirit that has been borrowed from America, and is commonly alluded to as "the yellow press." The influence of a bad example of that kind is naturally to be traced in various ranks of society, although it may be hoped and believed that the sterling qualities of our nation as a whole remain untouched, just as some of our leading newspapers retain their high traditions unsullied by the ribaldry, the unblushing lies, the callous prejudice, and the greediness that have brought in a rich harvest of wealth, honours and power to the pioneers and proprietors of the new journalism. Curiously enough, medical men show signs of being somewhat intimately affected by the new journalism. The ancient traditions of the profession sternly forbade anything in the shape of public advertisement, either the puff direct or the puff oblique. Direct advertisement, such as circularising by handbills, was dealt with by the General Medical Council as an offence to be purged only by disfrocking the culprit, while indirect newspaper puffing was punished by exclusion from societies and by other ways in which professional ostracism can be exercised. All this, however, appears to be gone by the board, so far as the consultant ranks of the profession are concerned, although, be it noted, the Council keeps as vigilant an eye as ever upon the ethical behaviour of the general practitioner. A favourite plan of advertisement has been the signed letter to the lay editor, and of late years this has multiplied to an amazing extent, until the names of leading medical men are almost daily before the public, sometimes in connection with the particular specialty with which they are connected. Recently a personal interview with a leading hospital specialist upon the subject of syphilis went the round of the lay press. The most striking instance of departure from the older and more dignified code of ethics was the publication about a year ago of a round-robin of congratulation to the editor of a London newspaper with regard to his conduct of a certain matter, attested by a large number of medical men, who appended qualifications and hospital posts to their names. Another glaring instance was the request for a Royal Commission upon venereal diseases signed by a group of well-known medical men, with a like exhibition of posts and titles, a document that went the round of the lay press. Only last week extensive advertisements were circulated of a "Family Medical Encyclopædia." In the advertisement columns appear a number of names of well-known men in the medical world, with qualifications and posts. Notices have at the same time appeared in reading matter of the newspapers; one of these expressly says: If you want to consult anyone on cancer, you cannot do better than go to Mr. So-and-so, of such a hospital, or, for skin, go to Sir Blank Blank, and so on. One can only commiserate with those that have been pilloried in this fashion, and wonder vaguely how they came to be mixed up in such a galley as that of a Family Encyclopædia. The whole incident implies an entire reversal of all our old traditions. It looks as if the American spirit were sweeping away all the ancient landmarks. We have good reason to suspect that the medical movement in England is being engineered by astute Yankee journalists. If this sort of thing be winked at by the General Medical Council, the next step will be open paid advertisements by medical men in lay newspapers. Certain it is that the monopoly of self-advertisement will not be allowed to remain in the hands of the few. Why should a man in high position as a consultant assume an unfair advantage over his rivals? The publication of names, titles and appointments already mentioned would justify almost any sort of newspaper publicity, bought or unbought, by the rank and file of medicine. The free advertisement of medical books, for instance, would be quite a natural sequence. Now that the ball has been set rolling, who can foretell the end? Is the future likely to revert to the honourable reticence of former methods or to become freely and frankly a hustling, advertising, auction-mongering profession? Lastly, what will the general practitioner have to say to future General Medical Council prosecutions for handbill distribution? As a matter of fact, one of the medical men whose names have been so widely advertised is a member of the Council, to which it may be surmised some sort of explanation will be forthcoming.

CURRENT TOPICS.

The Meaning of the Word.

Our average thinking is very slipshod. Our arguments are largely processions of words of whose meaning we have but the vaguest idea. The fact that we have never thought about the meaning of the words we use often leads us astray. The commonest words are the ones we know least about. What do we mean by insanity? What is the essential difference between a disease and a symptom? Those are questions that most of us could profitably think about for quite a long time. They are not the only ones. Freud's work, psychanalysis, and so on, has attracted a fair share of our attention during the last few years. All psychoneuroses are traced back to sex by the followers of this school. Every "psychic trauma" and every dream has its origin in sex, and our most ordinary actions are unconscious sex symbolism. It is easy to mock at these theories. It would be easier still if the serious work of the Freudians were not the most telling parody of its own intentions. Many of us hear the mockery and probe no deeper. Or, if we are stimulated to further efforts, we join the band of esoteric jesters. And all because we have not thought about the word sex. Short common words are our chief offences. More confusion has arisen over words like "I," "God," and "be" than about any of the lengthy terminological exactitudes that are coined daily. Each of us has a meaning for "sex." Each knows his neighbour has one too. No one troubles to find out how far the concepts coincide. Sex may mean almost anything. One of the most easily demonstrable of its connections is æsthetics and all that is implied thereby. But most of us would laugh if our taste in ties was deemed part of our sexual life. The only point we object to in the psychotherapists' terminology is

that they lay undue emphasis on "sex" as applied to their work. The spirit of sex and its attributes is so universal that its presence could be assumed in the absence of the word. This would tend to illuminate and clarify much that at first sight seems obscure.

Perils of the Loaf.

THE grossly careless way in which food is exposed for sale in the streets and in shops has, on more than one occasion, been commented upon in our columns. Public opinion has already been awakened, to some extent, as regards the necessity for protecting milk from contamination from its source to the consumer, but little, if anything, has been accomplished in the shape of safeguarding bread from a like defilement. It is true that a few firms have now decided to supply loaves in hand-proof wrappers, but such a means of protection for bread is by no means universally adopted. The suggestion of Dr. William Ewart, put forward at the annual meeting of the Pure Food and Health Society of Great Britain last week, that bread might be covered with some inert gelatinous substance which could be peeled off as required strikes us as being a useful one. As things are at present, the loaf received by a customer in the afternoon has been handled by all sorts of hands or exposed to road dust, so that, however much one may like crust, it is often necessary in self-protection to cut it off. In public restaurants it is no uncommon sight to see ladies fingering the rolls and pieces of bread provided in baskets with gloved hands that have perhaps previously caressed a lap-dog or taken hold of the greasy rail of a motor-'bus, before finally selecting the one they fancy. It is not straining at a gnat to insist that this sort of thing should be rendered impossible or that the loaf supplied to our tables should be kept as free from germs as sterilised milk. To be truly consistent, every loaf of bread sold should bear a guarantee, not only of purity of manufacture, but of freedom from microbic contamination, in the same way that a certificate of purity may be demanded in the case of milk supplied by every large dairy.

Reserve Force.

The mysterious quality known as reserve force is a wise provision of Nature which stands, or should stand, us in good stead in times of emergency, such as a long illness or a protracted mental or physical strain. Unfortunately, many persons continually draw upon their reserve strength to such a degree that they are quite unable to meet any extra demand that may be put upon their physical energies. The physiological explanation of reserve force is not easy to understand, for it has been usually supposed that every effort of such a muscular organ, say, as the heart is a maximal one, and that the life-motto of cardiac muscle may be expressed in the familiar phrase, "All or nothing." Later investigations have shown, however, that the contractions of the heart vary in strength to a far greater degree than was thought possible. Professor A. E. Boycott (*a*), of the University of Manchester, believes that certain elements in an active organ remain passive while others are engaged in work, and that a rotation of activity most likely occurs whereby all parts of the organ are enabled to work and rest alternately. Any organ which exhibits moderate functional activity has only a proportion of its elements active, and this activity is probably succeeded by a period of inhibition, so that when the next moderate activity requires performance a different set of elements is brought into play. Thus an organ is endowed with reserve force, for when an extra effort is required all the elements can be brought into action, since the state of inhibition is only relative to the intensity of the stimulus. Professor Boycott considers that some such conception of the basis of reserve force may throw some light upon one of the greatest problems in pathology, viz., the focal distribution of lesions. It may be that the patchy grouping of diseased cells in the liver or kidney is due to the action of toxic agents upon cells that are actively working, and, therefore, in a state of receptivity. Such an hypothesis is not incompatible with modern physiological theories.

(*a*) *Medical Chronicle*, January, 1914.

Friendly Wine.

WE have long been taught that alcohol in any form is an undiluted curse. It rots the body, wrecks the mind, obliterates the moral sense, and destroys all other parts of humanity not included in these heads. It makes a man a brute wallowing in an abomination of inebriation. It has been considered as a drug, and its effects have been studied by physiologists. We are not warmed by it, but the reverse; our output of energy after its use is decreased, and alcohol is convicted of being injurious to man and only fit for the use of spirit stoves and bottled snakes. In short, it is the fashion to tilt vigorously—at windmills. Alcohol in excess is no doubt harmful. Anything in excess is harmful. But exaggeration never strengthens a cause. It is hard to condemn a daily pot of beer or glass of claret. Great minds, including the Psalmist, Omar Khayyam, Edgar Allan Poe, St. Paul, and Swinburne, have sung the praises of wine. It is a great factor in our conscious happiness. Wine does not create. It inhibits inhibitions. It makes no man a brute who was not one before; it only uncovers his brutality. Æschylus calls wine the mirror of the heart. Poetic fire and good talking follow the bottle. Tongues are loosed, and peace, love, and harmony prevail. And the moral of all this is that some men should have wine and others should not. Civilisation may restrain a savage, or cramp the pinions of a genius; alcohol loosens the bonds. *In vino veritas*—wine strips us to the world. We are not pleading for intemperance. We merely wish to point out that it is not the essential of the grape that lies so heavily upon us, but excess in the using of our bottled sunshine. The fact should be self-evident, but it is these obvious things that need most pointing out.

The Temporary Administration of Sanatorium Benefit.

THERE must still be many instances in which only a temporary scheme of administering sanatorium benefit to insured workers can be arranged for in boroughs and urban districts. The machinery of State Insurance inevitably takes time to get into proper motion, yet it is essential that tuberculous patients should be dealt with as efficiently as possible under the circumstances. Dr. B. C. Stevens, Medical Officer of Health, Barnes Urban District Council, has offered some valuable hints and suggestions as to how this may be accomplished in an economical manner. The visionary "first-class hotel" is not a necessity, and, indeed, may be reckoned as outside the calculation of the Act. All that is needed is a clean, airy ward, which may be provided by the local authority in a spare wing of an isolation hospital. A typhoid ward, originally planned for five beds,

will take eight consumptives, and one planned for three will accommodate five. Such a ward should be supervised by the matron and placed in charge of a sister with special experience in the management of tuberculosis cases. Shelters may be placed in the grounds of an isolation hospital as far away as possible from any infectious block. A good revolving shelter will cost about £20, whereas a hutch shelter can be got for about £4. At the dispensary attached to such premises, or placed at a convenient distance therefrom, a nurse should be in attendance, and when such arrangements have been approved by the Local Government Board, the local authority may then, after having provided for its own needs, offer its services to the county or neighbouring authorities for the treatment of their patients. Bacteriological work may be undertaken at a local laboratory or in the isolation hospital, if one exist, and the support and co-operation of medical practitioners in the neighbourhood should be enlisted. Altogether, Dr. Stevens' hints are of the greatest value as constituting a good outline scheme for the practical administration of sanatorium benefit.

Coal Dust and Miners' Phthisis.

The daily struggle of the miner with the forces of Nature renders him, as everyone knows, subject to conditions which make his industry one of the most dangerous in which any man can find employment. From time to time the fact is forced upon public attention by the occurrence of some terrible disaster, such as that which took place recently at Senghenydd, in South Wales. In the third of the Milroy Lectures, just delivered before the Royal College of Physicians of London by Dr. Frank Shufflebotham, on "The Hygienic Aspect of the Coal-mining Industry of the United Kingdom," the effect of mine-dust upon the health of the workers was specially described. The greatest danger of pneumonokoniosis is that it leads to functional disablement of the respiratory organs, though the Coal Mines Regulation Act has, happily, been instrumental in checking the prevalence of fibrosis of the lungs, or miners' phthisis, to a great extent. The statistics of the Registrar-General show that the mortality figure for miners from diseases of the respiratory system was very much greater before the passing of the Act than now; for at the present time fibrosis of the lung among miners is practically non-existent, its disappearance being attributable to the enforced improvement in the ventilation and illumination of mines, and to shorter working hours. Fibroid lung, such as potters suffer from, is rare among coal-miners, and true anthracosis does not seem to entail disablement. It was, therefore, concluded that coal dust is not an irritant of the lung. Dr. Shufflebotham suggests, however, that if shale dust and flue dust were used in mines to adulterate coal dust with a view to the prevention of explosions, the siliceous character of the shale and flue dust might adversely affect miners' lungs. He also pointed out that the spraying of mines to render the coal dust less liable to explosion might cause a humidity which, when added to high temperature and darkness, might be deleterious to health and prove favourable to the development of ankylostomiasis, now practically unknown in British coal mines.

PERSONAL.

Dr. F. Coates has been appointed Attending Physician to the Forster Green Hospital, Belfast, in place of Dr. J. E. MacIlwaine, resigned.

Dr. Donald C. A. McAllum has been elected President of the newly-formed Scottish Society of Anæsthetists.

Dr. Frank Heasman has been appointed Physician to the Royal Victoria and West Hants Hospital, Bournemouth.

Dr. J. Bright Banister, M.D.Cantab., F.R.C.S. Edin., M.R.C.P.Lond., has been appointed Surgeon to Out-patients at the Chelsea Hospital for Women.

Professor Peter Thompson, M.D., Professor of Anatomy in the University of Birmingham, has been appointed a Fellow of King's College (University of London).

Dr. Hildred B. Carlill, M.A., M.D.Cantab., M.R.C.P.Lond., has been appointed Physician to Out-patients at the City of London Hospital for Diseases of the Chest, Victoria Park.

Dr. Charles Joseph Singer, M.D., of Magdalen College, Oxford, has been awarded the Philip Walker Studentship in Pathology, of the annual value of £200 and tenable for three years.

Sir J. Bland-Sutton, F.R.C.S., is the hitherto anonymous donor of £15,000 for the purpose of defraying the cost of a new institute of pathology, to be erected as a department of the Middlesex Hospital.

Amongst the candidates recently selected by the Council of the Royal Society to be recommended for election into the Society are Drs. Arthur Edwin Boycott and Henry Hallett Dale, and Professor D. Noël Paton.

Dr. Harry Campbell, M.D., F.R.C.P., will read a paper on "The Treatment of Syphilis of the Central Nervous System" at the meeting of the West London Medico-Chirurgical Society, on Friday, March 6th, at 8.30 p.m.

Dr. F. R. L. Atkins, of Loughborough, was entertained at the Town Hall last week by a large company upon the occasion of his leaving the district, and an illuminated address was presented to him in recognition of his valuable professional services to the town.

Dr. Frederic Wood Jones, D.Sc., M.B., B.S., M.R.C.S., will deliver two Arris and Gale Lectures at the Royal College of Surgeons of England to-day, March 4th, and Friday, March 6th, at 5 p.m., on "The Morphology of the External Genitalia of the Mammals."

Dr. Arthur E. Giles, M.D., F.R.C.S.E., M.R.C.P., will deliver an address on "Meditations based on 1,000 Abdominal Operations at the Prince of Wales's Hospital," at the meeting of the North-East London Clinical Society, to be held at the Hospital, Tottenham, N., on March 5th at 4.15 p.m.

Dr. Bernard Hart, M.D., Lecturer on Mental Diseases, and Dr. F. H. Thiele, M.D., B.Sc., F.R.C.P., Lecturer in Bacteriology and Immunist at University College Hospital Medical School and Pathologist at University College Hospital, have been appointed Fellows of University College (University of London).

Dr. R. T. Leiper, Helminthologist of the London School of Tropical Medicine, and Wandsworth Scholar, has left London for the East, accompanied by Surgeon E. L. Atkinson, R.N., and Mr. Cherry-Garrard, both of whom accompanied the Antarctic Expedition, for the purpose of ascertaining the mode of spread of the trematode diseases of man, especially bilharziasis.

CLINICAL LECTURE
ON
THE AGE FOR PROSTATECTOMY.

By PROFESSOR F. LEGUEU, M.D.,
Surgeon to the Tenon Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

AT what age should prostatectomy be practised? The reply to this simple question may seem straightforward enough, viz., just as soon as the troubles which it is the object of the operation to relieve supervene. But that hardly helps us, because we then have to ask, Well, what are the troubles which will decide us to advise an operation.

During the last few years opinions have undergone a steady change. Little by little we have been insisting on less and less functional disturbance as a justification for the operation. It is no longer an operation reserved for the aged, and year by year the age for operation gets earlier. Now this entails both advantages and drawbacks, and it is to these that I propose to devote my lecture.

When, in 1905, perineal, and subsequently hypogastric, prostatectomy emerged from the chaos of old-fashioned methods which had so far occupied the attention of surgeons, the operation was only performed in patients who presented grave troubles, viz., serious retention, complete or incomplete. The operation was not without risk, and its benefits were as yet by no means certain, so that it could only be offered to those who stood to lose nothing, in the sense that they had nothing to lose.

It follows that only old men from seventy to eighty years of age presented the conditions held to justify the intervention. Even at this extreme age the operation is not as grave as one might suppose, because to reach that age the subjects must be in a fair state of health, and this weighs when it comes to an operation. All the same some of them succumbed from the mere fact of their advanced age who would have survived had they been operated earlier.

As for persons who suffered only from occasional attacks of retention or dysuria, some hesitation was felt in recommending an operation to remedy a condition the gravity of which would not as yet be fully recognised. Then, too, there were good reasons for this expectant attitude. To begin with, the necessary recurrence of the accidents was contested; it was urged that a first attack of retention might not be repeated for months or years; in other words, the accidents are not regular or constant in their course. Then, too, the operation was attended by unquestionable risks which were more substantial in the earlier days of its introduction than now. Lastly, the patient, possibly still young, dreaded what I may call genital death, *e.g.*, the suppression of all sexual desire and sensation. The impression of perineal prostatectomy still haunted the minds of people, and hypogastric prostatectomy, still young, had not yet revealed its advantages on this question. Both surgeon and patient, therefore, had good reasons for hesitating until the progress of the symptoms cornered them both.

At the present time the matter requires to be reconsidered on a fresh basis. To begin with, the gravity of the hypogastric intervention is steadily diminishing. The perineal operation, it must be remembered, was never a grave one, and its trifling mortality enabled the earlier operations to inaugurate it definitively on the strength of reassuring statistics. The inadequacy of the perineal operation, however, led, little by little, to its being abandoned; it only half-cured, it left distressing infirmities behind it, and was bound in time to be supplanted by Freyer's prostatectomy, which is always more efficacious and more generous in the matter of a perfect cure. Consequently, in discussing the question of gravity, it is this operation which I have in view.

Now, this operation is progressing year by year, and the statistics show steady improvement. It does away in great measure with the danger of hæmorrhage and septicæmia which had to be reckoned with in its early days, simply because we had not learned how to avoid them. Nowadays, the operation is extremely simple and the operative sequels are much reduced and curtailed. Within from fifteen to eighteen days the bladder has healed just as after simple cutting for stone, and the patients can go home in three or four weeks. The patient only runs the risks inseparable from an operation of any kind: embolism, pulmonary complications and the risks due to pre-existing morbid states especially of the kidney. It is from renal insufficiency that death results in most of the fatal cases, consequent upon ascending infection or previous hydropiginous or uræmigenic nephritis. This is the one great danger, the stumbling block of prostatectomy, consequently it is well to hesitate before operating on subjects whose renal condition is unsatisfactory.

Even from this point of view, however, would it not be advantageous to do the operation earlier? The older the patient the more chance there is not only of his having renal lesions but of these being more advanced. The younger they are the greater the hope of their not having grave disease of the kidneys, and the comparative integrity of these organs in any case markedly curtails the period of convalescence.

Things are so much simpler in the young patient. Complications are less to be apprehended; he is much easier to look after, and this simplicity goes for much in the ultimate gravity of the operation.

Here is a table showing the gravity of the operation in the thirty last cases from statistics bearing on upwards of a hundred cases:—

Between 55 and 60—8 operations with 0 death.
Between 61 and 65—8 operations with 1 death.
Between 66 and 70—6 operations with 1 death.
Between 70 and 81—8 operations with 2 deaths.

The average mortality of 13 per cent. in this limited number is much less under 60 years of age, since recovery followed in every instance. It is

true that it is not veryhigh in patients over seventy, because past this age more attention is paid to contra-indications, and "undesirables" are rigorously rejected, but, all the same, there is a noteworthy difference, all in favour of the operation under sixty years of age.

(2) Another argument used to cause the operation to be delayed, viz., the genital impotence that almost invariably followed the perineal operation. This used to scare the younger patients, but it does not apply to hypogastric prostatectomy, so that it constitutes a further reason for not postponing the operation when otherwise indicated.

It may be urged that, after all, this is a trivial matter, in view of the age of the patients, but the patients themselves do not look upon it in this light. With hypogastric prostatectomy the ejaculatory ducts are usually left intact, the hypertrophied part of the prostate being above the vermumontanum, below which the ducts are situated, so that they escape injury. Should they be accidentally injured, which does sometimes happen, this is exceptional, whereas by the operation from below they are severed at the first incision.

It follows that, as a rule, the patient still has erections and desires, even actual emissions, though this, it is true, usually takes place into the bladder and comes away with the next micturition, nevertheless the patient experiences normal sensations in proportion to his age. No doubt, in aged subjects, the genital awakening after the operation is not always as satisfactory as they might wish, but in younger subjects—and this is the important point—the reproductive function is not interfered with as the result of the operation, another telling argument in favour of advancing the age for the operation.

(3) Other benefits follow the operation and militate in favour of its early performance. With regard to vesical contractility, this, with few exceptions, remains latent so long as the prostate impedes the passage of urine. It is annihilated but not done away with, and for however long a time the bladder has been condemned to impotence it regains its strength on the morrow of the operation. I can recall the case of a patient who had suffered from complete retention for seventeen years in whom the retention disappeared completely after the operation and the bladder retained its contractility for the rest of his life. This is a striking instance of the retention of bladder contractility, in spite of an impeding prostate. At the same time we must concede that chronic infection is a cause of sclerosis which may impair the bladder muscle, hence the desirability of not waiting too long.

Side by side with these arguments which are commonly advanced there are others, more recent and not as well known. In some still unpublished researches which I have been making with Dr. Gaillardot we have been able to satisfy ourselves that the hypertrophied part of the prostate, the part which the surgeon removes in the operation, exerts a certain toxic influence on the organism. This toxicity is manifested by changes in arterial tension and by circulatory disturbances, the physiology of which enables us to establish clearly its extent and its bearings.

Doubtless, this toxicity exerts its effects on the possessor of a hypertrophied prostate, and although we are not in a position to state exactly how the symptoms are manifested, there can be no doubt of the fact, so that the removal of this source of intoxication cannot fail to improve the general health of the subject.

This is another reason for operating early on the victims of prostatic hypertrophy, and this being so, I am in a position to draw certain conclusions based on the preceding considerations. My opinion is that the operation should be performed as soon as we get signs of prostatic adenopathy without waiting for the severity of the symptoms to become proportionate to risks, which are now in great measure non-existent. If the symptoms set in early why not deal with them forthwith, whatever the patient's age? He has everything to gain, and this is what I mean when I say that every advantage attends the performance of prostatectomy at an earlier age.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by F. G. Crookshank, M.D.Lond., M.R.C.P., Physician (Out-patients) to the North-West London Hospital; Assistant Physician, the Belgrave Hospital for Children; formerly Assistant Medical Superintendent, the Northampton County Asylum. Subject: "Epilepsy and Epileptics."*

ORIGINAL PAPERS.

POINTS OF CLINICAL INTEREST IN THE DIAGNOSIS OF ABDOMINAL DISEASES. (a)

By R. J. M. BUCHANAN, M.D., F.R.C.P.,

Honorary Physician to the Liverpool Royal Infirmary; Professor in Forensic Medicine, Liverpool University; Lecturer on Clinical Medicine, Liverpool University.

Pain in relation to disease elsewhere than in the abdomen is of interest. It is not uncommon to have definite abdominal pain in connection with thoracic disease, this especially in broncho-pneumonia of children, which is often heralded by pain referred to the umbilicus. On the right side pleurisy may give rise to pain in the region of the appendix, and in one instance, operation had been considered advisable when my examination revealed pleuritic friction in the lower right lateral region of the chest. Pain referred to the adomen is not uncommon in empyema, and even after resection of rib it may become chronic. In one case met with, the abdominal pain was so severe as to simulate a perforated gastric ulcer, and the abdomen had been opened, but nothing was found. The pain persisted, and three months later, when the patient came under my care, I discovered an old contracting empyema on the left side, which was treated surgically with good result.

Pericarditis may give rise to pain and tenderness in the epigastrium, with vomiting and with rigidity of recti, and may simulate abdominal disease. Lesions of the spine and spinal cord sometimes produce abdominal pain, and may simulate gastric ulcer, especially when vomiting is present. This I have seen in locomotor ataxy in the pre-ataxic stage: the patient, a woman, many years ago had the ovaries removed for abdominal pain and vomiting, without relief. This operation was followed by an anterior gastro-enterostomy, after which I saw her with incessant regurgitant vomiting. The abdomen was again opened; the surgeon undid the gastro-enterostomy and turned it round, did an entero-enterostomy and removed

(a) *Liverpool Medico-Chirurgical Journal*, January, 1914.

some gall-stones, stitched up the kidneys and liver for proptosis. There was relief for a time, but after some years the patient turned up again with severe abdominal pain and gastric crises, with established locomotor ataxy. Appendicitis of larval type often causes epigastric pain, but with no definite time relation to the ingestion of food, as in gastric or duodenal ulcer; it may also cause pain simulating lumbago, sacro-iliac disease, or right-sided sciatica, several cases of the latter having been cured by appendectomy. In acute pancreatitis, pain in the spine is a severe symptom, and is increased by the slightest movement.

In partial obstruction of the ureter paroxysmal pain may occur in the iliac fossa. In one case this resembled ovarian pain, and ovariotomy was performed; later the left kidney was examined by another anterior incision. The attacks of pain persisted, and the patient was seen by me: nothing could be discovered by abdominal examination at the time. On admission to hospital a minute quantity of pus was found in the urine, the bladder was "separated," and but little urine came from the left ureter; what did contained traces of pus. The ureter was catheterised and a block discovered; it was afterwards filled with collargol and X rayed and the block seen. Excision of the left kidney, which was disorganised, with the ureter as far as the block, was followed by complete recovery.

It is not uncommon to have attacks of colicky pain due to arterio-sclerosis; in one case the iliac arteries and abdominal aorta could be felt as if injected with wax.

Spasm of the abdominal muscles may be at times so pronounced as to simulate malignant growth and render diagnosis difficult. In some cases it is sometimes almost impossible to make certain, unless an anæsthetic be given, but it is useful, when convenient, to palpate the abdomen while the patient is reclining in a warm bath, which completely relaxes the muscles. This spasm is especially a feature in women who have an otherwise lax abdomen from repeated pregnancies, and in whom the hand can be passed down between the recti. In one instance the condition was most marked, the contraction simulating a mass in the hypochondrium resembling an enlarged gall bladder. In another instance the resemblance was so marked that the surgeon refused to operate as there seemed to be a great mass of malignant growth in the epigastrium, but the symptoms denoted gall-stones. It was found, however, that the mass occasionally seemed to disappear under the palpating hand. After watching and noting this on different occasions, I persuaded him to open the abdomen, other signs of malignant growth being negative, with the result that a gall-bladder was found containing many stones, and malignant growth of the stomach absent.

It is not uncommon also for peristalsis of the stomach or gut to produce local tense distensions which under the hand may feel like solid growth, but which fade and recur from time to time. It often occurs, and almost permanently localised at the proximal side of an obstruction, and is of value as a diagnostic sign of the latter. In one instance such a hard swelling had been present in the right iliac fossa for several years, associated with periodical attacks of pain and vomiting. It simulated a hard tumour in this region. On palpation I found that the swelling varied in tension, and peristalsis of the gut leading to it was present. The abdomen was opened and a constriction found, which was cured by short-circuiting. The ileum was enormously hypertrophied and contained numerous jam-stones which were passed later.

The occurrence of nodules in the skin and subcutaneous tissues is an important diagnostic sign of visceral malignant disease, and it is with the "caressing hand" that they are more easily discovered. They may appear before any special symptoms arise. In cases I have seen they have generally been associated with carcinoma of the stomach or pancreas. They may be felt in the abdominal aponeuroses and sheaths of he recti. At an early stage of the growth they may be visible. In one case an umbilicated red nodule appeared on the skin; it was excised, and on microscopical examination was regarded by the pathologist as a malignant adenoma of sweat glands; there were no other symptoms. Shortly afterwards another appeared, and I decided that it was a herald of visceral growth. Within a week jaundice came on, and the patient succumbed to malignant disease of the pancreas. When such nodules appear, operation is out of the question, as they are indicative of widespread metastases.

In some cases they occur in "showers" at distant parts, and it is peculiar that when such crops occur they do not seem to increase in size locally. In one instance I have seen the trunk and limbs covered with such nodules from pancreatic growth.

Let us turn to more special affections of the abdominal contents.

In association with diseases of the stomach, it is not uncommon to find the so-called "globus hystericus," a true symptom of gastric and duodenal ulcer. I believe it to be due to spasm of the pharyngeal muscles and upper œsophagus. In one case of duodenal ulcer the spasm had been sufficient to prevent swallowing and cause regurgitation at meal-times.

Peristalsis of the stomach, where chronic ulcer and thickening or growth of the pyloric end or duodenum have caused obstruction, may sometimes be easily visible; but when it is not pronounced, it may only cause local bulging to the left of the middle line, and I think this local distension an important sign. It is useful to kneel by the reclining patient and look across the abdomen from right to left. In health the curves of the two recti are on the same level, and move equally. When there is increased peristalsis, an arch is visible in the left, which is higher than that of the right, and this can be seen to rise and fall. I have noticed this in many cases when the X-rays have revealed vigorous contractions and delayed transit.

Loss of appetite is an important and primary symptom in gastric carcinoma, whereas in gastric ulcer it is inconstant and capricious; in duodenal ulcer it is hardly affected, voluntary refusal of food being ruled by the amount of pain. The tongue in gastric ulcer is often pointed, red, and irritable; in carcinoma it is generally pale, and with a peculiar smooth, silvery surface; in duodenal ulcer it may appear quite normal.

Pain and vomiting in gastro-duodenal disease have peculiar characteristics, although in some cases of gastric ulcer of the mucous type pain may be absent. When ulcer is established it generally comes on after ingestion, increases in severity, and is followed by vomiting, which gives relief; in

duodenal ulcer the onset of pain may be erratic or classic in type, is not often associated with vomiting, and when this occurs, it generally does so in the evening or late at night. Many duodenal cases are free from pain until after the midday or evening meal. Vomiting is, however, artificially induced in old-standing cases with narrowed pylorus, to relieve nocturnal painful distension.

Pain in gastric carcinoma may be quite absent, but when ulceration takes place often becomes constant, but aggravated by food. Vomiting is not constant, but in many cases occurs independent of any pain or the ingestion of food, and may be distressing. The vomit has the characteristic appearance when malignant growth has eroded the mucous membrane.

I have noted with interest in a few cases when gastro-enterostomy has been performed, and there was doubt about the nature of the ulcer, that when it is malignant, vomiting may not be relieved at all, or if it be, then it returns early and without concomitant pain.

The occurrence of occult blood in the stools is fairly constant in simple ulcer, intermittent in duodenal, constant in both simple and malignant ulcer in both vomit and stools.

Constipation is a feature of malignant disease ; not so in simple gastric or duodenal ulcer.

If, after the onset of gastric symptoms, enlarged glands appear at the lower part of the left side of the neck, behind the inner third of the clavicle, the diagnosis of malignant disease of the stomach is almost certain. They sometimes precede the abdominal symptoms, and in all cases of enlarged cervical glands occurring in adults, the abdomen should be carefully examined. I have only seen these glands twice on the right side.

Anæmia is an interesting feature in stomach disease. Simple gastric ulcer is very often associated with anæmia, especially in young females, and is generally chlorotic in type and severe. Cases of duodenal ulcer may be placed in two classes, the florid and plethoric, and the anæmic, the latter due to repeated small hæmorrhages. In carcinoma the anæmia is often severe, secondary in type, with leucocytosis. This anæmia may be the earliest symptom. If, after an attack of hæmatemesis or melæna, recovery from the anæmia does not occur within three or four weeks, it indicates malignant rather than benign disease. When gastro-enterostomy is performed and at the time there be a doubt as to the true nature of the ulcer, and anæmia does not decline, it is probably malignant, and this even though there be gain in weight.

Hour-glass constriction of the stomach is by no means easy to diagnose ; there are two signs which may help : the squelching noise when the stomach is pressed transversely with a hand at each end ; and the fact that in certain cases a test meal given cannot be regained a short time afterwards, for it may have passed rapidly through to the distal pouch. Again, vomiting in such cases is ineffectual, as the food may have passed on. The possibility of washing out the proximal pouch only before operation may leave the distal one full, and I have seen the distal pouch at the operation the larger of the two and full of " bismuth meal."

The history of hour-glass stomach is generally one of classic gastric ulcer years before, with intermittent outbreaks and remissions, no marked loss of nutrition until the constriction becomes very narrow, and vomiting occurring late in the course of the disease.

X-ray examination is of the utmost value in demonstrating the presence of hour-glass constriction.

Perforation of an ulcer may be unaccompanied by severe shock or collapse, the only sign being a rapid pulse. In a case I observed the pulse was 84 ; there was no pain after the onset, no temperature, simply distension. The latter, however, dislocated thoracic organs and simulated left-sided pneumothorax. The patient walked from Lime Street station to the Infirmary and carried his portmanteau. He was prepared for operation, but the surgeon refused to open the abdomen, judging the case pneumothorax. I was asked to see the case the following day (thirty hours after), the patient complaining of nothing but distension and dyspnœa. I could not discover a pneumothorax, but considered the condition abdominal, as there was a previous history of gastric pain after food. The abdomen was opened and the peritoneum found flooded with food, pus and lymph, and a perforated ulcer present.

In occasional cases, perforation may be accompanied by irritative shock, with restlessness and irregular movements simulating chorea. A case illustrating this came under my observation. The patient, a woman about fifty years of age, had had three of these choreic attacks within a short time.

On examining the case I was not satisfied about the chorea, and noticed an increasing distension of the abdomen, which felt tumid, but not painful. The patient was practically moribund. At the autopsy a large cancer of the stomach was present with an opening into the peritoneum, which contained the food of many days, with pus and lymph. The chronic condition was very similar to the restlessness and irritability of peritonism which is seen in traumatic and other cases, where there is effusion of blood or pus in the retroperitoneal tissues.

While on the subject of peritoneal affections, it is interesting to note that perigastric adhesions are often due to small leakages, and accompanied by occasional exacerbation of stomach symptoms. These attacks are often paroxysmal, and associated with transient pyrexia. Such cases experience aggravation of pain on assuming the erect posture and during exercise, even in an interval. In one instance there had been several of these pyrexial attacks, in one of which perforation, followed by hæmo-peritoneum, proved fatal.

In septic infections of the peritoneum the abdominal wall has a peculiar boggy feeling to the examining hand. Œdema of the wall may occur, and this is in my opinion a pathognomonic sign. In one case a woman was admitted to my ward with signs of extreme prostration and peritonism, free from pain, no distension and no fever. The onset had been gradual. There was marked œdema of the anterior abdominal wall over an area about 9 inches in diameter. The patient died a few hours after admission, and the autopsy revealed what seemed to be primary pure streptococcal peritonitis, as no causal focus could be discovered. I would like to point out here that post-abortive or parturient septic peritonitis may occur with suppuration, even when the uterus appears clinically normal. I have met with several such cases. When the pelvic peritoneum becomes inflamed, frequency of micturition, or the desire, and pain during the process, are common sym-

ptoms. This occurs in appendicitis, and in males the pain radiates to the penis and may simulate renal colic pain. In suppurative cases a peculiar discharge from the rectum may occur in gushes resembling pus, and it may be thought that a pelvic abscess has burst into the rectum. The material, however, is not pus, and the microscope reveals only cells from the bowel wall with thin mucus and some crystals. Such a discharge points to pelvic suppuration and demands operative interference.

It is not uncommon in peritonitis to have friction on auscultating the abdomen. It is a soft-toned friction in contrast to pleuritic. It is a helpful sign in perforated ulcer, and by this means the position of the perforation may be located. In one case I located the ulcer at the œsophageal-gastric junction; at the operation the hole was found in this position and had to be reached with "cleft palate" needles. I have noted this friction within an hour or two of perforation.

In a case supposed to be one of salmon-poisoning the gastric symptoms cleared up, but the patient ran an irregular temperature, and pulmonary phthisis was feared. I was asked to see the girl seventeen days after the onset, but could find nothing in the lungs; the heart's apex was raised a space or more, which led me to look for mischief below the diaphragm. The epigastrium was distended and the pyloric region tender, with the upper segment of the right rectus "on guard." Auscultation of the peritoneum revealed local friction over the pyloric area, and perforation of a pyloric ulcer was diagnosed, with local abscess. The abdomen was opened, and a drachm or so of pus was drained from a small localised pocket communicating with a minute perforation in the stomach. The patient made a good recovery. Had no operation been done, this patient might have recovered to have repeated leakages with febrile attacks and paroxysmal pain.

Tubercular peritonitis with marked distension of the intestine often gives rise to phenomena indicative of pleural effusion, and, strange to say, on the left side: I have never seen it on the right. I have seen it in children in varied degree, in adults two or three times, but this peritonitis is not so common in them. The lung is really collapsed, the spleen pushed up, and the heart dislocated to the right side. In all cases but one I repeatedly explored the pleura, to find it dry. In one case which gradually recovered with tuberculin treatment, this thoracic peculiarity disappeared as the distension passed away.

Phlebitis in relation to malignant disease is deserving of notice. In all cases of phlebitis, especially in middle age, careful examination of the whole subject should be made for malignant growth. It is sometimes the earliest symptom, and when malignant disease is discovered the latter is generally beyond interference. I have seen it in quite early ovarian carcinoma in a lady, when the small lump felt in the abdomen was thought to be simple fibroma uteri; but from the presence of phlebitis in both calves, I feared the lump was malignant, which it eventually turned out to be. I have met with it in carcinoma of the rectum, affecting the dorsal vein of the penis; in both arms and legs and pulmonary veins in malignant liver; in the superficial veins in the left of the abdomen and Scarpa's triangle in left ovarian growth; in carcinoma of the stomach, with secondary deposits in the liver, in a sailor thought to be suffering from scurvy; in carcinoma mammæ, in malignant disease of the sigmoid, in malignant disease of the thyroid and other instances.

I consider it not only of diagnostic but of extreme prognostic value.

In malignant disease of the liver for which no primary focus can be found by abdominal palpation or denoted by symptoms, the rectum should be examined, and not seldom the original growth will be found there.

Again, disseminated peritoneal growths of doubtful origin may be traced to a primary focus in the testes, which should always be examined.

I would like to mention the fact that unexpected and recurrent attacks of diarrhœa simulating colitis in adults with anæmia are often indicative of malignant growth in the colon, more commonly the descending colon or sigmoid flexure. I can recall several instances of this.

On the other hand, constipation coming on in elderly people who previously have been regular, with or without pain in the sacral region, may be due to early rectal carcinoma before local signs are manifest. Enlarged prostate in males, retroverted, enlarged, or malignant uterus in the female, are often causes of constipation, and I would advise that in all cases of constipation a rectal examination should be made. In all cases of so-called sciatica examine the rectum.

Polymastia in stomach cases, although a sign of degeneracy, and often associated with neurasthenia, occurs commonly in organic disease.

THE EVOLUTION, ANATOMY AND DISEASES OF THE ANTHROPOID APES. (a)

BY PROF. ARTHUR KEITH, M.D., F.R.S., LL.D.,
Conservator of the Museum, Royal College of Surgeons, England.

PROFESSOR KEITH, in opening his lectures, expressed the opinion that the blood-relationship between man and the great anthropoid apes—the gorilla, chimpanzee and orang—is becoming more apparent and certain. At the present time a close study was being made of the more primitive races of mankind with the object of throwing light on the stages which the more civilised races must have passed through as they emerged from a wandering and entered upon a settled mode of existence. When, however, the conditions of human existence at a much earlier stage which culminated in the evolution of the most primitive forms of man, were realised, inferences had to be based on the conditions under which anthropoids now live in their native habitats. In passing from a study of human races to an examination of anthropoid races the first great difference is that while all existing forms of mankind are so closely allied they must be regarded as mere modifications of a single species. The great anthropoids were structurally so different that they must be regarded as three separate genera, so great are their structural differences. At one time in the evolution of man it may therefore be supposed that the "family" Hominidæ was composed of equally diverse members or genera; indeed, geological discoveries of recent years have revealed the former existence of human types so different in structure that they are recorded as representing separate genera of men. It is further supposed that at a very early stage these human genera had a restricted distribution, such as are found to hold true for living forms of anthropoids. The gorilla, which until recent years was supposed to be confined to the French Congo, had been found by German naturalists to extend to the northern boundaries of the Camaroons, and it is possible that it

(a) Abstract of Six Hunterian Lectures delivered before the Royal College of Surgeons of England on February 16th, 18th, 20th, 23rd, 25th and 27th.

may even reach the neighbouring British territory of Nigeria. The distribution of the gorilla is much wider than was originally supposed, for in 1903 a form of gorilla was discovered on the eastern side of Africa, in that part of German East Africa which lies towards the Belgian Congo. Although in the Belgian Congo itself the gorilla has not yet been found, it is possible that colonies may exist there which will connect the outlying eastern settlement with the main family of the West Coast of Africa. The gorilla population, all told, probably does not exceed 20,000 or 30,000 members.

There is no example in the modern civilised world of two distinct races, or sub-species, of mankind occupying the same territory as equals; one is recognised as the superior or dominant race. In the anthropoid world it is different; gorillas and chimpanzees occupy the same territory as equals. Chimpanzees have a much wider distribution than the gorilla. They not only occupy the French Congo, but extend northwards along the West Coast as far as Senegambia; southwards, they are said to occur as far as the Portugese settlement of Angola. When Schmeinfurth, the traveller, crossed the watershed between the upper waters of the Nile and the Congo in 1866, he encountered the chimpanzee. Emin Pasha collected their skulls during his campaigns in the Equatorial Soudan. Sir Harry Johnston found that at one time it extended into Uganda, and Livingstone found it in territories which now lie within the boundaries of North-east Rhodesia. The chimpanzee race is thus more widely spread than the gorilla; it is more adaptable, cleverer and more cheerful than the gorilla. The lecturer stated that, although a census had never been attempted, chimpanzees and gorillas would not outnumber the inhabitants of one of our moderate-sized English towns. As Africa opens up they will quickly disappear. If they are to be studied in their natural state they have to be studied now.

The gorilla and chimpanzee, although separated by considerable differences in structure, are clearly closely related in origin, as they have so many characters in common. Yet they occupy the same areas peacefully and without any form of intercourse. The fact is also of interest to the student of early forms of man; it opens the possibility in the past of different genera of men being evolved side by side within the same territory. Among chimpanzees and gorillas the same tendency to the production of local races or varieties as among men is found. Thanks to the enterprise of the Hon. Walter Rothschild, the materials for the establishment of the various races, sub-species and species of gorillas and of chimpanzees is being brought to England.

The orang, the third of the living genera of anthropoids, is found in the equatorial belt of the Far East. In Borneo and Sumatra English naturalists owe a great debt to Dr. Charles Hose for supplying them with information and specimens relating to the orang. In 1889 Dr. Emil Selenka collected the skulls of nearly 300 orangs and established the fact that local varieties do exist. The orang, however, has apparently changed very little in recent geological times, for although Sumatra and Borneo have been separated since the Pliocene period at least, the Sumatran and Bornean orangs have not diverged to the extent of forming separate species. In their evolutionary tendencies the orang and gorilla have diverged in opposite directions. In the gorilla the lower limbs have been strengthened and modified for the support of the body—in some degree recalling the human condition. In the orang the arms have become the special organs of locomotion, while the lower limbs have undergone retrograde changes.

The gibbons are also classed with anthropoids, but they form a family apart. They stand to the great anthropoids much as the great anthropoids stand to man. They represent an early phase in anthropoid evolution.

Brain Development.

In dealing with the brain development of anthropoid apes, Professor Keith said that it was well-known that the size of brain depends to a considerable extent on the size of the body; a bulky animal required a larger central nervous system for the administration of its trunk and limbs than a small one. The difference in size of brain between man and the great anthropoid apes could not be due to size of body, for the gorilla and orang outstripped man in weight and in most dimensions, and the adult chimpanzee, in respect of weight, was nearly man's equal. In point of size and form of brain, the gorilla stood rather nearer to man than either the orang or chimpanzee; in certain minor features, however, these were the more human. Between the smallest human brain and the largest anthropoid there is a great difference, but this is rather in degree than in kind. Amongst human races are found individuals with a brain which measures as little as 1,000 cubic centimetres or as much as 1,800 cubic centimetres. Amongst the great anthropoids the brain fluctuates in size between 300 and 600 cubic centimetres. Amongst small anthropoids the gibbon and siamang, the brain varied from 100 to 150 cubic centimetres, which was also the brain capacity of the larger of the ordinary or dog-like monkeys found in both the Eastern and Western hemispheres. In the group of living animals of which man forms the terminal member there are thus two breaks in the brain series—one between the small and large anthropoids and one between the latter and man. Fifty years ago such breaks were cited as arguments against the theory of evolution, but it is now recognised that the opposite is the case. The animals which possessed the sizes of brain at present missing from the series are the extinct intermediate forms whose fossil remains are yet expected to be discovered. Professor Eugene Dubois' discovery of Pithecanthropus in 1891 helped to fill the blank between the largest anthropoids and the smallest human brain—the difference between 600 cubic centimetres and 1,000 cubic centimetres. The brain of Pithecanthropus is estimated to have been 840 c.c. In the opinion of Professor Elliot Smith a brain must reach a size of 950 c.c. before it can be regarded as capable of exercising human faculties. The brain of Eoanthropus, the fossil man lately discovered in Sussex, so far as regards its bulk at least was not a bridging form; it rises far above the lowest human limits in point of size.

At birth there is very little difference in size between the brain of the human baby and that of the large anthropoid ape. The period of active brain growth ceased in the anthropoid infant before the end of the first year, whereas in the human baby the period of active growth continued until the third or fourth year. In monkeys and small anthropoids the period of active growth was over at birth, and it was evident that the prolonged infancy necessary for the growth of the human brain was possible only with a high development of the maternal instinct. Monkeys are particularly attentive to their young, and it has been observed that the baby ape in the Zoological Gardens seeks the mother's teat almost until the time of another birth. The similarity between the ape and human brain is much more than a superficial resemblance. Forty years ago it was discovered that when a certain area of surface or cortex of the monkey's brain was excited by electrical stimuli definite movements in the body resulted. It was thus discovered that the centres for the higher control of bodily movements had an orderly representation in a certain area of the cortex or grey matter of the monkey's brain, known as the "motor areas." Further research demonstrated the presence of similar centres in the corresponding but more extensive area of the anthropoid brain. Motor areas of the anthropoid and human brains are so similar that the surgeon is guided when operating on the human brain by the observations made on the brain of anthropoids by physiologists. The motor areas occupy a relatively small part of the cortex of the brain; the rest of the brain when artificially excited gives no apparent response. Hence it was necessary to resort to other methods to discover the use and nature of the other parts of the brain—the method which has proved most successful so far is based on the fact that each area of the cortex which is known to have a particular function has also its own particular structure. The recognition of this principle has caused students of the brain to throw their older

machinery of research on the "scrap heap" and set out to demarcate the human brain anew. In this endeavour to chart out with exactitude the areas of the human brain, British investigators, such as Professors A. W. Campbell, Elliot Smith, and Drs. F. W. Mott and E. Schuster, have taken a leading part. Professor Elliot Smith recognises as many as thirty distinct structural areas in the cortex of the human brain. Superficial observers might suppose, said the lecturer, that modern research is revealing the conditions of localisation of function postulated by the founders of "phrenology." What scientists were discovering, however, was not the localisation of those indefinite attributes of the mind, such as those described as "ideality," "destructiveness," and "amativeness," but centres or areas which have become developed in connection with the sense of sight, hearing, feeling, touch, etc. In lower primates these primary centres occupy almost the whole cortex of the brain. In the evolution of the higher forms, secondary or tertiary areas arose round those primary centres. In the human brain these secondary and tertiary areas—"association areas" they are called—reach their highest development. The large extent of these association areas are connected with judgment and memory, and constitute the distinctive features of the human brain. With the evolution of the human brain one other structural character appears. In the lower apes the right and left halves of the brain are remarkably alike in structure and function. As the association centres become developed a specialisation of the two sides arises, some of the centres being more developed on the right and some more in the left half of the brain. The highest control of muscles and movements have become vested in the left hemisphere of the brain, which dominates the right half of the body. Right-handedness is a result of this specialisation.

LONGEVITY IN APES AND MEN.

Regarding the natural term of life amongst anthropoids knowledge was only to be founded on indirect evidence, for it would not be possible to ascertain how long anthropoids lived in a state of nature. Captive anthropoids never died of old age. Of all the anthropoids the chimpanzee was the one which took most kindly to captivity; the record life-time for a captive animal is 15 years; and of the hundreds which had been brought to Europe in recent times there were not more than six which survived ten years' confinement. Death took place in every case before all the teeth were cut. The evidence which had been collected points to the life-periods of the great anthropoids, the gorilla, chimpanzee, and orang as approximating the human rather than the monkey terms. In ordinary monkeys the prenatal life-period is seven months; the period of growth—of infancy and adolescence—is about seven years and the total span of life about 21 years. In anthropoids the prenatal period is apparently nine months, the same as in man; the period of growth about 12 years, and judging from the wear of the teeth and the changes which took place in the skull and skeleton with age, it was possible that the full term of life amongst great anthropoids might extend to 35 or 40 years. It was interesting to note that the gibbons—the small and most primitive type of anthropoid—shared the same life periods as the ordinary monkeys. The prolongation of the periods of life or the slowing of the rate of development appeared with the evolution of the large-bodied primates to which group the great anthropoids and man belonged. Evidence has led to the conclusion that the natural periods of human life have been lengthened by civilisation. There were no accurate data relating to the longevity of primitive human races because a people has to reach a comparatively high stage of culture before individuals begin to note their age. Those who have had opportunities of studying primitive races, such as the native tribes of Australia, assert that maturity is reached two or three years earlier than among Europeans, and that all the signs of old age become manifest 10 or 15 years earlier. A distinction, however, must be made between a premature senility, which is the result of hardship and a natural senility, which would occur even under favourable conditions. When all allowance is made there was reason to believe that civilisation has really extended the vitality of the human body.

TUBERCULOSIS AND APPENDICITIS IN APES.

The close relationship of anthropoid apes to man was shown by their susceptibility to human diseases. When Metchnikoff and Roux began their experiments on syphilis ten years ago they found that the chimpanzee could be readily infected while the lower apes and monkeys were inoculated with difficulty. Such a result was to be expected from the observations which Professor Nuttall, of Cambridge, and Dr. Friedenthal, of Berlin, had made on the blood relationship of man and anthropoids. At the beginning of the present century scientists discovered that in its vital reactions the blood of anthropoid apes was very similar to human blood; that of old-world monkeys was less human, while, under the same test, the monkeys of the new world were still further removed from man. It was therefore to be expected that those diseases which find their most suitable medium for multiplication in human blood would find the next best in the systems of anthropoids. As man evolved some of his diseases must have kept pace with his constitution. Tuberculosis was a disease of another kind; its bacillus was not restricted to one particular kind of blood. Anthropoids were very susceptible to the human tubercular bacillus. When an ape became infected tuberculosis followed in its most acute form.

Like man, the anthropoid apes possessed an appendix and were therefore liable to appendicitis. There was no evidence to show that they suffered from this disease in a state of nature; it was only when kept in captivity that they suffered from this common human affliction. The earliest recorded case of appendicitis in chimpanzees occurred in an animal which died in the Zoological Gardens in 1836; the complaint was then called typhilitis. Recently Dr. Weinberg, of Paris, had seen ten cases of appendicitis amongst captive chimpanzees. Three of these suffered from the recurrent chronic form; the others were cases of acute appendicitis.

Caries of the teeth, which is so common amongst civilised peoples, is practically unknown amongst anthropoids. These animals, like primitive races of man, however, are liable to toothache. The hard nature of their food leads to the crowns of the teeth being worn down so that the pulp becomes exposed. Abscesses or gumboils then form at the roots of the teeth. The chimpanzee, which has the most human-like teeth, is more liable to root abscesses than the other two great anthropoids—the gorilla and orang. In captivity young anthropoids, when their permanent teeth are cutting, are very liable to suffer from abscesses in their jaws—due to infections from the mouth.

An arboreal life renders anthropoids liable to jungle accidents. Dr. Duckworth, of Cambridge, found that in 14 skeletons of adult wild orangs, four of them showed healed fractures. At one time or another their owners had suffered a bad fall. In some cases as many as four bones of the body had been broken, probably the result of a slip and fall. The orang is evidently the most clumsy climber of the anthropoid family; at least he suffers from fracture of the limb bones more frequently than his African cousins—the chimpanzee and gorilla. The lecturer considered that it was marvellous how they recovered. Sometimes the union at the seat of fracture leaves much to be desired from a surgical point of view; in other cases the results are such as would satisfy the most fastidious surgeon.

SEX DIFFERENCES AMONGST ANTHROPOIDS AND MEN.

Professor Keith considered that so far as concerned sexual differences amongst human races, the account given by Mr. Havelock Ellis in his book entitled "Man and Woman" was by far the most detailed and complete. Amongst man's nearest allies, the anthropoid apes, a great difference separated the two sexes. Amongst the various forms of anthropoids, as amongst human races, the males had the largest brains. The greatest sexual difference in brain-size was to be found amongst gorillas, where the male had a brain 18 per cent. larger than the female. Amongst orangs

the male brain was 14 per cent. larger; in human races the average male preponderance was 12 per cent. Amongst chimpanzees the difference was only 8 per cent. in favour of the male. That difference was largely due to the greater bulk of the male. An increase in the size of the body was necessarily attended with an addition to the size of the brain, but not necessarily to that part of the brain concerned in the higher acts of the mind. The size of brain was only one of the attendant sexual characters amongst anthropoids; the canine teeth also varied with sex. They were weapons of offence and defence, and hence the male anthropoid had not only the longer and stronger canines, but he was furnished with stronger muscles for their effectual use. The stronger muscles required larger jaws, more massive skulls, and greater bony crests for their attachments. There could be no doubt, from what was known of the effect of rendering an individual sexless amongst men and all higher animals that all the sexual characters of the great anthropoids—their greater size and strength, the larger teeth and brain—depended entirely on substances thrown into circulation by the sexual glands. In all cases the permanent characters of the female were those of the non-adult male.

The age changes were not only more rapid in their appearance amongst anthropoids than amongst human races, but they were also more considerable. A man's skull was a thickened child's skull, furnished with greater jaws; but in passing from infancy to adult years the skull of an anthropoid became transformed in its most essential features. There was also no doubt that the anthropoid skull kept on growing in size all through the life of the individual, especially in males. In gorillas and chimpanzees a tendency for the hair to turn grey occurred early in adult life, while wrinkling of the skin was present even at birth. In certain human races, such as the Bushmen of Cape Colony, wrinkling appeared prematurely—in young adults.

In seeking for the means which had led to the differentiation of the great anthropoids into so well marked forms, as the gorilla, the chimpanzee, and orang, Professor Keith said that a clue to some of Nature's deepest secrets had been found. The study of diseases of growth and development amongst men threw a new light on the problem of the origin of species. In the diseases known as acromegaly the whole physical appearance of a man or woman was changed in a few years. In this disease the characters which were assumed had a real similarity with the features which characterise the gorilla. At the present time the structural changes which occurred in acromegaly were supposed to be due to a disturbance in the secretion of the small pituitary gland. It was therefore a legitimate inference to suppose that the evolution of the gorilla may have resulted from a primary change in the action of the pituitary gland. The thyroid gland in the neck could also bring about a series of remarkable changes in the human body of quite a different type. The essential characters of the orang, both mental and physical, were such as might have resulted from an alteration in the action of the thyroid gland. There was no doubt that a fuller knowledge of the function of those obscure and small glands—known as glands for supplying internal secretions to the body—would place the problem of evolution of species in quite a new light.

Ancient Forms of Anthropoids.

Discoveries made during the last eighty years show that there existed in India, during Pliocene times, at least three great anthropoids. One of these, judging from the account lately published in the Memoirs of the Indian Geological Survey by Mr. Pilgrim, was closely related to the African gorilla. Another, known by the name of Palæopithecus, was related to the modern chimpanzee of Africa on the one hand and to the orang or Borneo on the other. The third form was the anthropoid known as Dryopithecus, the remains of which were first discovered in Southern France over sixty years ago. The discovery in France carried the history of great anthropoids back to the middle of the Miocene period; so far no trace of them has been found in strata older than the Miocene. Knowledge of these extinct forms of anthropoids rests on a few fragmentary jaws and a small number of teeth. Of the size and formation of their brain nothing is known. The fossil teeth and jaws do not indicate that the extinct anthropoids represent "missing links" in the anthropoidal ancestral chain; these fossil forms appear rather to have been cousins of existing types, with perhaps the exception of Dryopithecus. In this anthropoid there are certain features reminiscent of the gibbon, and some characters of the molar teeth have a human appearance. It is possible that some molar teeth found in Miocene and Pliocene deposits in the upper valleys of the Rhine and Danube, at present attributed to Dryopithecus, may have belonged to an early form of man. From discoveries of fossil remains man can be traced back to the beginning of the Pleistocene period, perhaps to the latter part of the preceding period—the Pliocene. The great anthropoids can be traced beyond the Pliocene, well into the Miocene period. Future discoveries will, thinks Professor Keith, most likely carry the history of man and anthropoid to a still more remote past.

OCULAR AND OTHER COMPLICATIONS OF SYPHILIS TREATED BY SALVARSAN. (a)

By. DR. D. F. REEDER,
Chief Eye and Ear Clinic, Ancon Hospital.

The most frequent and painful complications of syphilis are its effects upon the eye, manifested by iritis, iridocyclitis and keratitis. These affections are most frequently caused by acquired syphilis. However, quite a number of cases of interstitial keratitis are caused by congenital syphilis. Of all the eye manifestations of syphilis, iritis is the most frequent, while optic neuritis and retinitis are a good deal less frequent, but at the same time very much more serious in their consequences. Since May 14, 1908, there have been treated in the Eye and Ear Section of Ancon Hospital 182 cases of syphilitic iritis, while there were only 75 cases that were not classified as syphilitic.

The average time for these patients to remain in the hospital was about one month. Since the introduction of salvarsan, which has been administered intravenously by Dr. Herrick, we have treated fifteen patients with this drug, including one case of extensive nasal ulceration. The results in some of these cases have been most brilliant, while in others they were no better than with the ordinary mercury and potassium iodide treatment.

I desire here in a brief way to report a few of these cases.

Case 94,555.—The primary lesion appeared five months ago and iritis one week previous to admission. The eye was greatly inflamed and there was marked injection of the sclera. The ciliary margin of the iris had a small yellowish-white papule. The tension was plus and pain was severe. The Wassermann test was negative.

Treatment.—Inunctions of mercury were given daily and potassium iodide was administered in increasing doses. Atropine was given t. i. d. On the fourth day the nodule or papule greatly increased in size and the pupil gradually contracted. On the eighth day the growth was still increasing in size and gave evidence of its protruding through the sclera. The sight was practically lost. Notwithstanding the negative Wassermann it was decided to give him salvarsan. After its administration the patient had a chill, which was followed by nausea and vomiting, and his temperature was 99.5° F. By the third day the growth had markedly diminished in size. The pupil began to dilate and vision returned. The gummatous growth in the iris was entirely absorbed and the patient was discharged well three weeks after the salvarsan had been administered.

Case 94,676.—The primary lesion appeared two years

(a) Paper read before the Canal Zone Medical Association.

ago. Three weeks previous to admission iritis appeared in the right eye. The iris was inflamed and there was posterior synechia. The vitreous was cloudy. The Wassermann test was positive. Salvarsan was administered on January 24th, following which two Wassermann tests were negative. Salvarsan was again administered April 4th. The reaction was slight. Increasing doses of potassium iodide were given at this time, and the eye improved slowly. April 16th the Wassermann test was positive. On April 20th, salvarsan was again administered, and the patient's temperature rose to 100° F. Five weeks after admission the patient was discharged well.

Case 95,452.—The patient denied having had syphilis. There was a vague history of trouble in the eye for three months. There was a marked iritis and cyclitis with plastic exudate and posterior synechia. The Wassermann test was positive. Salvarsan was administered intravenously. The patient's temperature rising to 100° F. Improvement was rapid and twelve days after the administration of the drug, he was discharged well.

Case 94,249.—The patient denied having syphilis. There was perforation of the nasal septum with ulcerations in the nose. The Wassermann test was positive. Salvarsan 0.6 grams was given intravenously. No previous anti-syphilitic treatment had been received. The reaction was severe, the temperature rising to 103° F. Pulse 120. Nausea, vomiting, profuse perspiration, *Herpes labialis*, and mild delirium, with symptoms of acute arsenic poisoning. Three examinations of the urine were negative for albumen. For a period of one week after the injection the patient was very nervous and weak and took very little nourishment. Four weeks after, the patient was discharged from the hospital still weak, but the ulceration in the nose had healed. This man may have had interstitial nephritis.

Case 91,689.—Secondary syphilis with iritis and adenitis. Patient was admitted January 27th. The Wassermann test was positive. On February 7th, salvarsan was administered and the reaction was mild. The pain in the eye increased a few days after the administration of the drug, despite all efforts by means of local treatment to combat it. Later, potassium iodide was given. Improvement was gradual and the patient was discharged three weeks after the intravenous injection of salvarsan.

Case 91,964.—The patient denied ever having had a primary lesion, but a macular eruption was present all over the body and there was an iritis of both eyes. The Wassermann test was positive. Salvarsan 0.4 grams was administered February 16th. The reaction as indicated by the temperature was 101.5° F. March 2nd, the Wassermann test was positive. On March 10th, salvarsan 0.6 grams was administered. On April 30th, the Wassermann test was negative. Length of time in hospital, ten weeks.

Case 96,260.—Patient was admitted April 28th. He denied syphilis, but had a kerato-iritis of three weeks' duration. The Wassermann test was positive. On May 4th salvarsan 0.6 grams was administered. The temperature rose to 102.5° F. and there was a chill. By May 15th the improvement had been slight, and a second dose of salvarsan was given. The temperature rose to 103° F. The Wassermann test on May 25th was positive. Marked improvement was noted after the second dose of salvarsan and the patient was discharged from the hospital after seven weeks.

Case 94,493.—The patient was admitted May 23rd. The primary lesion had appeared four months before. There was iritis of the right eye with marked ciliary injection, a plastic exudate and posterior synechia. The Wassermann test was positive. Salvarsan 0.6 grams was administered intravenously and a negative Wassermann was obtained later. The reaction following the salvarsan consisted of a chill with a rise of temperature to 101.5° F. Improvement was rapid and the patient was discharged five weeks after the administration of salvarsan.

Case X.—Patient was admitted April 2nd with iritis of both eyes and an annular synechia. There was a plastic exudate and *Seclusio pupillæ*. The patient was practically blind. The acute inflammation in this case had subsided. The Wassermann test was positive. Mercury and potassium iodide were given together with an intravenous injection of salvarsan, 0.6 grams. Two weeks later the Wassermann test was still positive and 0.6 gram salvarsan was again given intravenously, after which the Wassermann test was positive. Salvarsan, 0.6 grams, was again administered. The patient is still in the hospital. There is no change in the eye except that a iridectomy has been done on his right eye with good results.

Case 98,170.—The patient was a boy three years old with interstitial keratitis, glandular enlargement, and Hutchinson's teeth. The Wassermann test was positive. On May 29th, 0.2 grams salvarsan was administered. Improvement has been very slow and the patient is still in the hospital.

Case 99,723.—The primary lesion appeared five years ago. Ten days before admission to Ancon Hospital the patient had received 0.6 grams salvarsan at Santo Tomas Hospital, at which time the Wassermann test was negative. There was a peculiar eczematous condition of the skin which was dry and scaly, and the patient gave a history of having had iritis one year ago. At the time of the administration of the salvarsan, no complaint was made of eye trouble, but he now states that he had had some pain in the eye a few days before. Two days after the injection the eye became inflamed and he has at present a well-marked attack of iritis, which is not much improved. Vision 20-100. This is either a case of iritis precipitated by salvarsan or one in which salvarsan failed to effect a cure, though injected at the physiological moment.

There has been a great deal written about the after effects of salvarsan. Most of these affect either the optic nerve, producing a neuro-retinitis, or the auditory nerve, producing deafness and vestibular disease; but whether this is due to the effect of salvarsan or to the syphilitic virus is an open question, as these complications arise in persons suffering from syphilis, when mercury and iodides are given, and more frequently when no treatment is administered at all.

Professor Finger, of Vienna, reports four cases of optic neuritis following salvarsan. In one patient he had given two doses of salvarsan, .45 gm. each, injected subcutaneously. To two patients he had given .4 gm., one of which had previously received thirty injections of arsacetin, and in the fourth case he had given one dose of .45 gm. It would appear from these cases that the dose was not sufficient to cure the syphilis and that in one case arsacetin had been previously injected, therefore it is not clear that salvarsan had played any *rôle* in the complication. Schamberg reports a case that had received .45 gm. subcutaneously, following which there was misty vision but improvement of the general symptoms, and later loss of vision in the right eye and some dimness in the left eye. Dr. de Schweinitz, who examined the patient, reported finding choked disc with retinal hæmorrhages. She was vigorously treated with mercury and iodide, and upon discharge had a vision of 20-40 in the right eye and 20-30 in the left. This proves Ehrlich's contention that the complication is due to syphilis and not to the drug.

In regard to the auditory complications, Finger reports three cases, one of vestibular nerve disturbance with recovery in a few days, and two of labyrinthine deafness without recovery. One had received .5 gm. and others .45 gm. injected subcutaneously.

The doses in these cases were, of course, inadequate to control the disease. Some have advanced the theory that the reason so many cases of auditory disturbance result from salvarsan is on account of the small bony canal through which the auditory nerve passes. In my opinion the real cause is the inability of salvarsan to cure permanently.

In looking over the records of Ancon Hospital since 1908, I find that optic neuritis constitutes five per cent. of the ocular complications of syphilis. The data are not available as to the exact number of the auditory complications, but of these there have been quite a few. Most of these cases had received practically no treatment before admission to the hospital.

Lohlein in an article abstracted in the *Journal of*

the A. M. A., May 27th, 1911, page 1623, reports that no benefit was apparent in nine cases of syphilitic parenchymatous keratitis in which he applied salvarsan; the involvement of the other eye was not prevented. Even supplementary threefold subconjunctival injection of 0.01 gm. salvarsan failed to arrest the corneal lesion. The failure of the drug in these cases cannot be ascribed to non-penetration of the drug into the cornea, as he demonstrated by experiments on rabbits with both subcutaneous and intravenous injection of the drug, and this is the conclusion that one would reach from the cases treated and reported here.

Haike and Wechselman report the combined study by an internist and an ear specialist of the action of salvarsan on the ear, reviewing what has been written to date in respect to the action of salvarsan on the ear. The conclusions from their experience and those reported in the literature are that syphilitic disease of the ear is amenable to salvarsan, in all its stages and in the inherited form. The salvarsan may benefit when the ear trouble has resisted mercury. The details of six cases are given, including a case of severe syphilis of the auditory nerve, with deafness for two weeks. They also report seven cases of the by-effects on the ear after the injection of salvarsan. In five of the seven cases the auditory disturbances were cured by repeated injections of salvarsan; in the others they subsided under mercury. (*Journal A. M. A.*, May 27th, 1911, page 1612, Abs.)

The fact that mercury and potassium iodide have cured cases of syphilis where salvarsan has failed is one of the most serious indictments against the drug. The conclusions that I would arrive at from the study of the literature and from the cases observed are that salvarsan is inadequate to cure all cases of syphilis, that one dose is not sufficient in any case, that salvarsan when administered in selected cases is probably harmless, and that most of the by-effects, if not quite all, are due to the disease and not to the drug. It will prove of great benefit in cases of fulminating syphilitic iritis, but mercury and potassium iodide should be given after the patient is well started on the road to recovery. Except for experimental purposes I would not consider it wise to depend on salvarsan for a cure.

OPERATING THEATRES.

WEST LONDON HOSPITAL.

Renal Calculus Simulating Hip Disease.—Mr. Aslett Baldwin operated on a youth, æt. 15, for renal calculi. Five years previously the boy was operated on for left-sided tuberculous disease of the hip; there were several scars in that region. During the latter part of this period he had complained on numerous occasions of pain which he referred to the same joint, and for which he had been sent to bed, this being followed by relief of the pain. When the boy first came under Mr. Baldwin's notice a few days before the present operation he was complaining of his old pain, but on examination of the hip itself, Mr. Baldwin concluded that it was free from disease, and on further investigation it soon became apparent that the pain was associated with the urinary system: there was frequency of micturition, and when the boy was up and about the pain was worse. The urine was examined and found to contain pus and blood. Radiographs were taken of both kidneys by Dr. Reginald Morton, which showed the presence of three stones in the right kidney and one in the left. This, Mr. Baldwin said, was a point of considerable interest, as the pain was all referred to the left side.

At the operation the patient was placed on his left side over a round cushion. Mr. Baldwin made an incision in the right loin; the kidney was found and brought out of the wound. The wound was packed with gauze, and, the pedicle of the kidney being held in the left hand to control hæmorrhage, an incision was made along the convex border of the kidney, and without great difficulty the three stones shown in the radiograph were found and removed. The incision in the kidney was completely closed with iodine fortified catgut No. 2, and the hæmorrhage altogether controlled. The kidney was then replaced and the wound in the loin closed, a moderate-sized drain tube being inserted.

After this operation on the right kidney the pain from which the boy had been suffering in his left side was completely relieved, though it had been present when he was in bed awaiting the operation.

A fortnight afterwards the left kidney was cut down upon and the stone removed on that side by a similar operation.

Mr. Baldwin said he thought this case was of very considerable interest, first because of the mistake which had been made in diagnosis with regard to the source of the pain; and, secondly, because, although there were three stones in the right kidney, the boy never complained of pain on that side. The case, he thought, showed the importance of not confining one's point of view to one aspect of a case, and also if pain is complained of in one kidney that we must not be satisfied with investigating that kidney alone, but should also examine the one on the other side as well. In this case, if the attention had been confined to the left kidney only the pain would not have been relieved. The case will also put us on our guard, he remarked, against concluding that a kidney is diseased when pain is complained of on that side, as the kidney under suspicion may be perfectly healthy and the pain referred from a diseased kidney on the opposite side. With regard to the locality of the pain complained of by the boy, he probably felt it in the kidney, the ureter, and perhaps in the bladder, and as he had had disease in the left hip, and the parts are very close together, he associated the pain with his old trouble, and it was only by careful questioning that it was found to be in his urinary organs.

The boy made an uninterrupted recovery and has put on flesh and grown to such an extent that he can scarcely be recognised as the same youth.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section of Ophthalmology.

Meeting held on Monday, February 16th.

The President, Sir Anderson Critchett, Bart., C.V.O., F.R.C.S.Ed., in the Chair.

Conclusion of the Discussion on the Subject of the Use of Salvarsan in Ophthalmic Practice.

Mr. W. Lang showed a case which, in 1908, developed sympathetic ophthalmia following a gunshot wound. Much benefit had occurred from giving salvarsan.

Mr. Parsons, discussing the case, thought it showed that sympathetic ophthalmitis was a general infection, and it would be difficult to believe that a purely local condition could persist for three years, the interval between the injury in this case and the subsidence of the sympathetic trouble.

Mr. Fisher also spoke of two cases in which Mr. Browning forecasted the onset of sympathetic trouble from the blood count.

The debate on the use of salvarsan was continued by Lieut-Col. R. H. Elliot, I.M.S. He said he had had no experience with neo-salvarsan. As he had had an experience of optic atrophy following the use of soamin, he asked the Surgeon-General's assistance in getting reports of cases in which the same calamity followed the use of salvarsan; but none were reported, and he believed the reason was that they did not occur; they were able men, and fully on their guard. On the other hand, it was their experience that those cases which presented signs of optic neuritis, of presumably syphilitic origin, acted excellently to the remedy. As the whole of a dose of salvarsan seemed to be eliminated from the system in ten days, he thought any trouble which was likely to arise would be evident

in a month or so, after which period no anxiety need be felt. In his large practice in Madras, the intramuscular method was abandoned in favour of the intravenous, largely on account of the pain caused by the former, which in many cases necessitated the use of morphia. A Wassermann was done in each case, and the administration was not continued after that test was negative. In no case did they abandon mercury and iodide, which were given in the intervals. The most startling benefits were obtained in recent or acute cases involving the uveal tract. One man was practically blind, with a congested eye, his vitreous was full of opacities, and a gummatous mass involved the ciliary body; yet within a week of using the remedy he could count fingers at 20 to 30 feet. His general nutrition also improved. With muscle palsies and optic neuritis the results were very satisfactory, though not with tabetic conditions. He knew of two deaths following the use of salvarsan, both in marasmic patients, who probably would not have lived long in any case. With regard to sympathetic ophthalmitis, Gifford, of Omaha, from the results obtained in it from atoxyl and salvarsan, argued that it was a general protozoal disease.

Mr. E. ERSKINE HENDERSON reported two cases of severe irido-cyclitis following cataract extraction on the eighth and tenth day respectively. Ordinary treatment supplemented by staphylococcal vaccines proved of no value, but after two doses of neo-salvarsan, both cases recovered. In one case, a man, æt. 51, successful needling later gave 6/6 and Jaeger 1 with correction. In the second case, a woman, æt. 72, an iridotomy would probably be necessary, as the pupil was considerably contracted.

Mr. Henderson stated that he was led to make a trial of the drug in these cases on the strength of the results obtained in sympathetic ophthalmia, as these two cases were of the type that might have led to that affection, and if the remedy was of use in the sympathetic eye, why not in the exciter?

Dr. ALEXANDER FLEMING said that when salvarsan was introduced into this country it was said to have ruined many eyes; but there seemed no real evidence that the drug had produced an evil effect on any eye; not any cases of optic nerve trouble had followed its use at St. Mary's Hospital. He preferred salvarsan to neo-salvarsan, though the latter was very easy to use. He had never seen much benefit from salvarsan in interstitial keratitis. In one case a chancre of the inner canthus disappeared in a few days under the treatment. In choroiditis the results were very rapid and complete. In one case an Argyll-Robertson pupil, in a case diagnosed by a physician as tabes, became a normal pupil under the treatment.

Major HARRISON thought the timidity felt about using salvarsan was largely due to the evil repute of atoxyl and soamin, but there could be no doubt about the beneficial effects of salvarsan. He had seen a case in which omission to use salvarsan on account of its supposed neurotrophic effect on cerebral nerves resulted in a calamity. He proceeded to discuss points in the *technique*, and expressed the opinion that as all the salvarsan given could not be collected in the urine, probably the drug was not entirely eliminated from the system as soon as was supposed. Still, by spacing out the doses at intervals of not less than a fortnight, any cumulative effect need not be feared. If a case seemed to indicate more frequent doses, he thought there would be little danger. He had not had any catastrophes in his practice with salvarsan.

Mr. J. B. LAWFORD read notes of a severe case of post-operative plastic iritis treated by neo-salvarsan, the patient being a man, æt. 60, the subject of acute gout. The operation was extraction and iridectomy. There followed hazy cornea, ciliary injection, exudation, and the formation of a hypopyon. A mixed staphylococcus vaccine produced no visible effect. Nineteen days after the extraction, .9 gramme of neo-salvarsan was injected intravenously, and in two days there was definite improvement; while four days later the hypopyon was very small, and the congestion was diminishing. He went home, but returned later, and the hypopyon had returned. A similar dose of neo-salvarsan was injected, and almost immediately the eye became brighter, and there was general marked improvement.

Mr. BROWNING, in answer to a number of questions, admitted that the blood count by which one could forecast the onset of sympathetic trouble was not infallible, but it was true in the great proportion of cases. The discovery of this particular blood count did not mean that the eye would be inevitably excised; efforts to save the eye would be persisted in as long as they were of any avail.

Mr. BASIL LANG pointed out that many of these cases of injury of the ciliary region occurred in children, and it should be remembered that the total number of leucocytes in the blood varied from the moment of birth until after puberty. Until the second or third year of age, 80 per cent. of the blood cells present were of the lymphocyte type, *i.e.*, large mononuclears, large lymphocytes and small lymphocytes. Therefore, finding a child with such a blood count must not be taken to mean that it was on the eve of sympathetic ophthalmia. He believed salvarsan to be a very good tonic, from his observation on cases.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, FEBRUARY 12TH, 1914.

The President, Mr. J. JACKSON CLARKE, in the Chair.

DR. WILLIAM HUNTER opened a discussion on

ORAL SEPSIS IN ITS MEDICAL AND SURGICAL ASPECTS.

He referred to the frequency with which oral sepsis is met with and the far-reaching character of its effects. Its seriousness lay not so much in its mere presence, but in its association with open wounds in the mouth. The peculiar anatomical disposition of the teeth made the proximity of sepsis a particularly dangerous one. He spoke of the frequency of tonsils and chronic inflammatory conditions of the naso-pharynx when oral sepsis is present. Septic gastritis was a common complication. Septic anæmia arising from this source was frequently superadded to other diseases such as phthisis, nephritis, and specific fevers, and might constitute a serious disease in itself. He regarded pernicious anæmia as a disease *sui generis*, but intensified by anæmia of septic origin, and treatment devoted to this factor had greatly improved the prognosis. He did not advocate such wholesale extraction of the teeth as was sometimes performed. What was needed was the advent of an era of antiseptic medicine comparable to that of antiseptic surgery.

Mr. W. H. DOLAMORE spoke from the point of view of the dental surgeon. He did not think that wholesale removal of the teeth was justifiable except in comparatively rare cases where severe systemic disorders followed.

Dr. C. BUTTAR said that he would like to ask the wholesale extractors and the vaccinists what proportion of their cases could be described as cures, and did the percentage justify the pain, the disappointment, and the distress of an edentulous lower jaw caused in those who were not benefited by the treatment? In his own practice, amongst 10 patients treated by different specialists only one professed to be relieved of his symptoms. He narrated several cases in which extreme measures had been far from satisfactory, and urged enthusiasts to consider carefully whether they were not doing rather more harm than good by this form of treatment.

Dr. G. COATS thought it was very questionable whether chronic irido-cyclitis was connected with oral sepsis. Post-operative inflammation might be due to it, and therefore septic teeth should be removed before intra-orbital operations.

Mr. D. C. L. FITZWILLIAMS corroborated Dr. Hunter's view that tuberculosis of glands was engrafted on adenitis arising from oral sepsis, and agreed with him as to the importance of septic teeth in causing tonsillitis.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

Meeting held Thursday, February 12th, 1914.

The President, Dr. David Walsh, in the Chair.

Dr. Alfred Eddowes showed (1) a case of lupus erythematosus, which he had shown on several previous occasions, and which of late had made unusually good progress. After doing very well on sour milk and other treatments, the patient appeared to be almost cured. Then she had an accident, after which she broke out violently with a fresh attack, and the disease looked as though it were going to be as bad as ever. He had instituted a special form of treatment, which he would describe in the discussion to follow, but while the patient was before them he asked the members to notice how very quiet the patches were. At one time the patient had the typical "snake skin" in the ears; this had disappeared.

(2) A case of lupus erythematosus of 18 months' duration, in which there was extremely little resulting disfigurement. The patient, a young lady, had the affection on and around the end of her nose. The little fresh cut which would be observed was the result of a deep puncture made a few days previously. The skin was of a good colour, and really did not look unlike normal skin. There was nothing of the parchment-like cicatrix generally seen in these cases. Freezing had been tried before he saw her, but had not done good. Now, whenever a nodule developed, the patient came up at once to have it punctured. His method of treatment by deep puncture was the outcome of a study of the pathology of the disease. With regard to the use of quinine, he had given up the sulphate, and now administered the tincture of quinine of the Pharmacopœia, which he found to agree with the stomach better than the sulphate, perhaps because it was a chloride. Now and then he still tried sour milk preparations because he had seen such great benefit from them two or three years ago. As to local treatment, he had seen cases treated by others and had treated cases himself in many different ways. Some fairly satisfactory results had been obtained with carbon dioxide snow, but generally that treatment was a failure. As the cause of the disease was unknown it appeared to him that one of the best ways of arriving at a rational treatment was to carefully examine the pathology. On examining a large number of different sections, the first fact he observed was that specimens were not taken deeply enough. He was surprised to find how deep they needed to be in order to get at the bottom of the trouble and obtain a complete picture of the pathology. One of the serious things which happened was the blocking of some of the deeper veins and the thickening of the arteries. This had the effect apparently of quickly stopping the leucocytosis which started in these cases, and in its place was produced a round-celled infiltration, which broke down, led to atrophy, and completely destroyed the appendages of the skin. One really got nothing left but the fibrous tissue of the cutis and an impeded circulation of the lymph. Often the lesions began as well-defined nodules, sometimes feeling like a thorn, such as were called, when occurring in an isolated form on the hand, "folliclis." He no longer saw any hope for very superficial surgical operations. They must go down to this cell infiltration at the base of the sweat ducts, sebaceous glands and hair follicles if they were to save the structures. Often they found symptoms of tension and a redness which disappeared with difficulty on pressure, there being lymph stasis and sometimes considerable pain, which, as they knew, meant tension. Surgery afforded the quickest way of giving relief. His object now, whenever he could feel a nodule, whether single or multiple, was to try to stop the process, which he knew would be destructive if allowed to go on. He applied a local anæsthetic upon the surface, and then took an ordinary lancet, held at an angle of about 45 degrees, and plunged it in, not vertically, but obliquely, to sever the base of the nodule. The result of this puncture was that they did not get a scar which could be seen: it healed up like a razor cut because it was oblique. He had an idea that there was a poison formed locally in these cases: there might not be micro-organisms, but an irritant poison which set up inflammation. A stagnating local irritant should surely be drained off as thoroughly as if it were pus. The relief was often very rapid indeed. The pain involved in the treatment was very small or non-existent if an anæsthetic was used. In order to prevent the collection of irritant exudation in the surface epithelium he applied alcohol in some form containing a little carbolic acid and camphor.

Dr. Walsh said that in treating these cases of lupus erythematosus they felt that they could do very little in many of them. Sometimes the patients recovered, and sometimes they did not, and if they did recover the dermatologist was not sure that his methods were responsible. The method brought forward by Dr. Eddowes was based on pathology, and he hoped it would be practised or tried by members of the Society. They were indebted to him for having brought it before them.

The President brought forward a case which had shown the typical lesions of lupus erythematosus and had cleared up under tuberculin treatment. A little roughness might be felt at one ear, which was all that remained of the former lesions. There were originally pale raised papules on the nose, and on the right arm there was a raised patch, healing in the centre, the size of a half-crown. The point about the case was that two of the lesions upon the ears, which were indistinguishable from lupus erythematosus, disappeared under tuberculin treatment. The gumma on the arm and the lupus erythematosus-like lesion on each ear had all disappeared as a result of tuberculin.

Dr. J. D. Benjafield gave the details of the tuberculin treatment given in this case. The injections were started on October 24th, and fourteen injections were given, more or less at weekly intervals, the dose gradually increasing, from one-millionth of a milligram at the beginning to one 2,000th of a milligram, which was the last dose. There was no reaction of any kind.

Dr. Eddowes said that he was quite willing to collect cases in which his own treatment had been followed, and to compare them after some time with those which had had Dr. Walsh's series of injections. And to make the comparison more definite, he would not use tuberculin unless he felt compelled to do so in the interest of the patients. When dermatologists, as now, were groping in all directions for improvements in the treatment of lupus erythematosus, they should leave no stone unturned to arrive at improved methods.

The President replied that different members of the group of cases called erythematosus might be due to entirely different causes. Possibly he had been dealing with one type with his tuberculin treatment, and Dr. Eddowes with quite another. Moreover, there might be even more than those two types. He was bound to say, however, that his own case, in which the lesions disappeared under tuberculin injections, was more favourable to this treatment owing to the obvious tubercular accompaniment.

Dr. Samuel raised the point as to Dr. Eddowes's definition of folliclis, and asked him also whether he distinguished lupus erythematosus from lupus erythematosus nodularis. In gauging cures of lupus erythematosus one had always to be on one's guard as to whether the cure were not a spontaneous one which is so common in lupus erythematosus for it to suddenly take a turn for the better as it were off its own bat.

Dr. Walsh also showed a case for diagnosis. The patient—a woman—had an eruption on the scalp, which began ten months previously as a spot and spread downwards along the forehead. The edge of the eruption when she first came to him was hard and much more definite than now. It was evidently progressive, and had the appearance of a tertiary manifestation, but the Wassermann test was negative, there was no specific history, and it had not been possible to isolate any organisms in the laboratory. About the time that the rash came on there was a history of a small lump in the thigh, which had cleared up. The diagnosis lay between acne necrotica and tertiary syphilis.

Dr. SAMUEL said that if he had seen the case in its present state without hearing the previous history of its course he would have regarded it as acne varioliformis, although he would have preferred as confirmation of that diagnosis to have seen the lesions spreading back on the scalp, which does not seem very evident here. But in view of the detailed description of the course of these lesions so minutely and ably described by Dr. Walsh, he was bound to admit that that description accorded more with a tertiary syphilide.

Mr. DENNIS VINRACE showed (1) a case of lupus erythematosus of the scalp of seven years' duration, which he brought forward in order to show the stationary condition of many such cases. When he first saw the case he used stimulants, and for several months liquid paraffin was rubbed in, and the case remained fairly stationary. There was an enlarged lymphatic gland in the neck, which the patient had had from the time she first came under his care, and also superficial scaling on the left auricle.

(2) A case of lupus vulgaris in a woman which had remained more or less on the side of the face for some three or four years. Initially the lesion was on the lobe of the ear on the left side. During the last month he had commenced treatment with lead, and the very marked colour practically disappeared. He had hoped that members would have been able to see the characteristic result of the lead applications, but the patient had come through the wind that afternoon, and now the condition looked as inflamed as it did when she came to him on January 12th.

(3) A case of secondary syphilis which had come to him with a story of having taken copaiba for eight days previously. The patient assigned his trouble to the bottle of medicine, quite ignoring all previous history.

Dr. G. NORMAN MEACHEN brought forward a case of

OCCUPATION DERMATITIS FROM ANILINE,

in a man, æt. 46. The case had several peculiar features. There was some specific history, the patient having had a chancre followed by "secondaries" fifteen years ago. He had been a chemical cleaner for the last twenty-five years, but had never had a similar eruption to the one he showed at present. During the last three months, however, he had been using aniline for removing stains from clothing, and the dermatitis from which he was suffering appeared to be due to the aniline. Both hands were affected, and the lesions over the dorsal aspects of the phalanges resembled lupus erythematosus or chilblains. The lesions over the ulnar side of the back of the right hand were raised, papular and dark red, and perhaps had something to do with his former trouble. The thenar eminences were eczematous.

Dr. WALSH said that he used to think that in these aniline cases the trouble was due not so much to the aniline, but to the arsenic contained in the aniline. He did not suggest that Dr. Meachen's case was not a pure aniline rash, but he considered that, as in previous cases of aniline workers, there was nothing in the rash inconsistent with arsenical dermatitis.

Dr H. C. SAMUEL showed (1) a case of syphilis of the palms in a young man, the condition coming on five months after the primary lesion. The patient had no idea that he had contracted syphilis until leading questions were put to him. It was rather a typical case of bilateral syphilis of the palms. The patient was now having intra-muscular injections of mercury. He had had one injection of neo-salvarsan and would, after ten injections of mercury, have a second "606." There was a scar of the primary lesion on the penis.

THE PRESIDENT said that he remembered bringing forward a case in which the only syphilitic manifestation was in the form of these round patches in the palms. He had great difficulty in persuading the patient that the trouble was syphilitic. The peculiarity was that the skin was the normal colour inside the ring of the patch. In Dr. Samuel's case the colour was pink. This was interesting, and probably had a relation to the more active process going on in the secondary infection.

(2) A case of dermatitis herpetiformis existing ever since childhood. In the case of this patient—a man—prurigo had been suggested, but the distribution and grouping were against that diagnosis. The lesions were good; there were not many vesicles at present, but they are visible from time to time on careful inspection, and the distribution affecting the flexures—which is absent in prurigo—and in the scapular and sacral regions was very typical of the condition of dermatitis herpetiformis. The patient had had syphilis ten years ago, but the skin condition dated from long before the onset of specific trouble.

Dr. EDDOWES inquired whether the patient had had any treatment with arsenic, as there was a good deal of pigmentation in mottled form.

Dr. SAMUEL replied that the patient was thoroughly treated for syphilis at the time, and that the lesions were now typically those of dermatitis herpetiformis, the grouping being most characteristic of that condition. The pigmentation referred to might be due to arsenic, although ringed pigmentation marking the sites of old dermatitis herpetiformis lesions are characteristic and often of diagnostic significance in that disease; (3) two cases of syphilitic manifestation. The first, in a young girl, was a secondary specific eruption plus a follicular type of secondary eruption which one did not see very often. The latter came out at the same time as the roseola. At first he was inclined to suggest ordinary acne, but personally he thought it really specific, as shown by the infiltration. There were all the typical secondary manifestations and primary lesions. The patient was now having mercury injections, and was going to have "606."

The second case was that of a single woman, with tertiary syphilis with a rather long history. A characteristic lesion on the leg had existed for six years. The Wassermann was triply positive. Eventually "606" would be given in this case also. He called attention to the very long localised history without other manifestations. The great depth and brawniness was a feature of the lesion, but it was quite free from the underlying tibia.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, FEBRUARY 6TH, 1914.

SIR WILLIAM J. SMYLY in the Chair.

FIBRO-MYOMA.

SIR WILLIAM J. SMYLY, in showing the specimen, said it was removed from a girl, æt. 21, on whom he had been asked to do on ovariotomy. He did not see the patient until the time of the operation on the 27th January, but he did not think he could have made a correct diagnosis even had she come under his observation sooner. When the abdomen was being prepared he felt something like a soft flaccid cyst. On opening the abdomen the uterus and ovaries were found to be healthy. On the right side was the tumour, which was shelled out of the broad ligament. Although it was cyst-like in appearance on a knife being inserted nothing came out. The tumour was entirely intra-ligamentous except a very small part which was embedded in the right wall of the uterus. The case was interesting from the point of view of diagnosis, and also on account of the youth of the patient. He had never seen such a large myoma in a girl at such an early age. The pathological examination showed the specimen to be a myoma.

LACERATION OF THE PERINÆUM AND ITS OPERATIVE TREATMENT.

Dr. HASTINGS TWEEDY read a paper on the above subject, which was published in our pages last week. (MEDICAL PRESS AND CIRCULAR, February 25th, p. 195.)

Dr. FITZGIBBON agreed with the view that it was of importance to lift the tongue of mucous membrane towards the vagina and away from the anus. It was his practice to suture the perinæum while the patient was in the lateral position, and before the placenta

came away, as at that time the anæsthesia was generally sufficiently deep to permit of doing so. He considered that an approximation of tear could be made just as well in the lateral position as any other, provided that it did not extend very far into the vagina. He suggested that in the left lateral position a tear in the left lateral sulcus could be seen, but for right side tears the dorsal position was necessary. He preferred silkworm gut on account of its non-absorbent qualities, and looked upon it as an advantage to have sutures which would not absorb lochia into the wound.

Dr. JELLETT did not consider that one could appreciate the extent or importance of tears extending up the posterior vaginal wall unless the patient was in such a position that this wall could be clearly seen. He did not think that this was possible in the lateral position. Repairing by sutures passed from the perinæum alone with the patient in the lateral position had a tendency to leave a tear of the posterior vaginal wall unstitched, so leaving a pouch communicating with the vagina. Even if the perinæum suture entered the levator ani muscle, it might very easily miss such part of the vaginal tear as lay above the muscle. He considered that the dorsal position was the most suitable for almost every part of obstetrical work, including normal labour, and pointed out the tendency in the practice of the Continent and of America to substitute the dorsal for the lateral position. He considered that it was quite easy to maintain the patient in the dorsal position for the purpose of suturing the perinæum, or for any other reason. He showed drawings of an operation to illustrate the repair of chronic lacerations of the perinæum, and called particular attention to the necessity for suturing the levator ani muscle separately. He had been performing this operation for the last six or seven years, and had quite abandoned the old Lawson Tait operation. There was not the least doubt that in the operation he described the levator ani muscle was sutured, and not, as had been suggested, one of the more superficial and rudimentary muscles of the perinæum.

Dr. SOLOMONS said it seemed to him that the most important part of the paper was that dealing with the repair of the perinæum primarily, as that operation concerned a greater number of practitioners than the secondary operations, which concerned but few in comparison. He thought it necessary that the best way for sewing the ruptured perinæum after birth should be determined conclusively so that patients might be left as well before their confinements as afterwards. He inquired what Dr. Tweedy meant by "support of the perinæum before the blood comes," as it had been his experience that the latter often occured while the head was still far up in the vagina. With regard to the question as to position, he always adopted the lateral except where the vagina was torn very high up and required catgut sutures. He looked with disfavour on catgut in ordinary tears of the perinæum and always used silkworm gut.

Dr. MADILL was sorry that tears of the anterior wall were not touched upon. Regarding the classification of tears he suggested grouping them as slight tears, large tears, and complete tears. The first heal uniformly, but he found the large tears did not heal up in many cases. Whether this was due to the use of catgut or not he did not know, but why they should not heal up if the operation was fairly aseptic he was at a loss to understand. He considered that there were objections to suturing lacerations in the second stage which more than counterbalanced the advantages. It was better to wait till the placenta was away before suturing.

Dr. MCALISTER said, to him the most interesting part of the paper was that dealing with old lacerations. As the result of work which he had taken part in last year, and of operations which he had seen, he considered that in those procedures where the muscles of the pelvic floor were exposed in the process of repair the muscle fibres first met with were not portions of the levator ani, but the remains of the transversus perinei profundus muscles. To display the levator ani muscle satisfactorily one must either retract, or in some cases temporarily divide and reflect the transversus perinei profundus. The levator ani fibres on each side thus exposed were brought together in the middle line in front of the rectum, after which the transversus perinei profundus muscles were dealt with in the same way, being united in the middle line superficial to the repaired levator ani muscle. In bad cases of prolapse such very thorough repair of the levator ani was particularly called for.

Sir WILLIAM SMYLY said he regarded the division into three degrees of laceration as of practical importance; the great majority of tears were slight, but there were bad cases in which the muscles were torn, and, as Dr. Tweedy had pointed out, tears through the sphincter muscle formed a distinct group. The object of the operation was to bring things back to their original condition, or as near to it as possible. The loose tongue of mucous membrane was the posterior vaginal wall, and by stitching it to the anterior end of the skin wound the triangular shape of the perineal body was restored, and the muscles should then be brought together between the vagina and the rectum. He preferred operating with the patient in the dorsal position, because, amongst other reasons, both hands were free, whereas in the lateral the left had to act as a speculum. As to the levator ani muscles, he thought what Dr. McAlister had said was right.

Dr. TWEEDY, replying to the remarks, said he recognised that the muscles held sutures very badly, and could very easily be cut through, and for this reason he described the operation which took in everything right up to the ischio-rectal fossa, and he considered that the most elaborate dissection would not enable more tissue to be taken in. In the fresh tear and the old tear the anatomical conditions were precisely similar. He again accentuated the use of a needle, sufficiently long and curved to take in enough fibrous sheath, as it would hold better than muscle. He was influenced in writing the paper by the knowledge that many differed from him as to the side position. He referred to the difficulty under which work had to be done, and said that the operation that could be conducted with the minimum amount of handling was the best for the patient, and this he contended was demonstrated by the low morbidity rate obtaining in the Rotunda where the smallest amount of interference was practised. Regarding lacerations in the anterior walls of the vagina, these were rarely attended to, and here also he considered that the minimum operative interference held good. He considered that it was hopeless to teach men to look for these tears and stitch them. He held that inquisitive midwifery could not be practised without increasing the morbidity rate. He always pinned his faith to the mass suture. The old Lawson Tait operation fell into disuse because it did not bring in the muscles, but the modified form of operation, in which the curved needle was used, worked admirably.

ULSTER MEDICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 12TH, 1914.

PLEURAL EFFUSION.

DR. CALWELL read a paper on "Some Less-known Points in Pleural Effusion," which was illustrated by lantern slides. He first drew attention to the fact that although the pressure on the abdominal and cranial cavities was positive, in the pleural cavities it was negative; this was due to the elastic retraction of the lungs. Dealing with the forces in one pleural cavity, he showed that the elastic retraction was greatest from the root to the axillary line as it cut the border of the lung, and this accounted for the rise of fluid to its greatest height, in this position forming Ellis's curve. In the interaction between the two lungs, the mediastinum was the rope in the tug-of-war. When fluid was poured out into one pleural cavity, the elastic retractive force of that side was lessened; consequently the healthy lung in moderate cases really pulled the mediastinum over. The pressure in the complementary pleural sinus was that of the abdomen, and so positive, consequently in early effusions fluid did

not descend into this space. When, however, more and more fluid was poured out, the pressure ultimately became positive; the mediastinum was now pulled over by the healthy lung and pushed over by the positive pressure in the affected side, and fluid now descended into this space. On the right side this could be proved clinically by auscultatory percussion, when an increased intensity of sound was heard as the percussing finger passed down the mammary line over dulness due to fluid to dulness due to liver. This stage of danger was marked by the rise of fluid in front to the second interspace.

The position, depths, and character of the fissures were then shown. Pleural effusion only affected the parietal portion so frequently as this portion was much the largest; effusions could be poured out into the diaphragmatic surface, the pericardial surface, or more important, the interlobar spaces; the retraction of the lung tended to open up these potential cavities, and at times pus formed between the lobes, giving rise to constant cough, hectic temperature, and varying areas of dulness. This pus might remain imprisoned there for some time, or spread downwards to the diaphragm, forward to the anterior end of the great fissure, inward to the pericardial structure, where it gave rise not infrequently to simple pericarditis. In using the exploring needle, one should mark out the line of fissure and the greatest dulness, and try first into the dulness and then into the line of the fissure towards the dulness. Simple loculated interlobar effusions might account for some chronic lung cases with obscure signs, ending ultimately in recovery.

SURGERY OF THE GALL-BLADDER AND BILE-DUCTS.

Mr. ANDREW FULLERTON read a paper on the above, illustrated by 30 cases without a death. He divided his cases into the following groups:—Those in which the gall-bladder was simply drained in 15 cases for calculus, cholecystitis, or chronic pancreatitis. In 11 cases the gall-bladder was removed as a primary operation, and in two cases as a secondary operation eight and two years respectively after the primary one of simple drainage. Recurrence of symptoms was the cause necessitating the secondary operation. In four cases the common duct was incised for the removal of calculi from it or the hepatic duct. In three of these the duct was drained, and in one immediate suture of the incision was carried out. In one case transduodenal choledochotomy was done for a small stone impacted in the ampulla of Vater. In one case the dilated common duct, which could not be emptied through the cystic duct, was anastomosed to the duodenum. This was a case of chronic pancreatitis in which apparently complete obstruction of the common duct was present. The anastomosis was carried out with the help of a small Murphy's button. The patient lived for a year after the operation. The cause of his death was not known to the writer. In one case a large subphrenic abscess appeared shortly after cholecystectomy. This was successfully treated by removal of a portion of rib and suture of the diaphragm to the parietal pleura before incision of the abscess. In two cases abscesses occurred after perforation of the gall-bladder by calculi. In one of these simple drainage was carried out, and in the other the gall-bladder with the calculi was removed. Chronic pancreatitis was present in a marked degree in five cases in the series. It was remarkable after operation how rapidly the patients put on flesh. This would seem to signify that the pancreas possessed considerable reparative powers. Mr. Fullerton said that though he had not to record any deaths in this series, he had been favoured with more than the usual amount of luck in several. He could not count on a continuance of such a mortality rate.

LUPUS.

Dr. RANKIN read a paper on lupus. He described the incidence of the disease. About one-third of the cases occurred on the nose, one-third on the body. In about half the cases the cheek was affected. Of the cases starting on the nose, the inside was found always to be involved. Eye symptoms, particularly dacryocystitis, were very frequent. These conditions always ante-dated the incidence of the disease on the nose outside, and a careful investigation of these points in the history showed that the disease almost invariably commenced before puberty.

The cases presenting lesions on the body started at a point about a joint, and spread in a circle, parts of which might disappear. On the cheek the common origin was from a tuberculous gland under the jaw, and the main line of advance towards the inner corner of the eye.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD FEBRUARY 19TH.

Dr. E. W. HOPE in the Chair.

MR. R. E. KELLY read a note on a

CASE OF FRACTURE—DISLOCATION OF SHOULDER.

The humerus was in three pieces, the head had become attached to the side of the shaft. Mr. Kelly freed it from the shaft and planted it in its proper position. It became united and gave an excellent result.

Dr. E. W. HOPE and Mr. RUSHTON PARKER joined in the discussion.

Mr. N. G. CHAVASSE reported a case of fracture dislocation successfully operated on by Mr. Douglas Crawford.

Mr. T. C. LITLER JONES related cases in which it had been necessary to remove the broken portion of the bone from the shoulder joint.

Mr. G. P. NEWBOLT referred to the value of pulling the arm right above the shoulder in the reduction of the dislocation.

Mr. R. E. KELLY, in reply, discussed the regeneration of bone.

Mr. F. C. LARKIN also intervened in the discussion.

Dr. N. PERCY MARSH gave a short paper on

THREE CASES OF LYMPHATIC LEUKÆMIA IN CHILDREN.

The respective ages of the children were 11, 4½ and 3. The three children died within a few days or weeks of the onset of the symptoms.

In his experience arsenic and blood serum were useless.

In concluding he dealt with the ætiology and pathology of the condition.

Dr. E. W. HOPE spoke.

Dr. T. R. BRADSHAW related a case and upheld the view that the essential pathology is that of a neoplasm.

Dr. H. R. HURTER referred to a case of multiple myeloma which ended in a lymphatic leukæmia, and suggested that such a sequence of events threw some light on the pathology of acute lymphatic leukæmia.

Professor R. J. M. BUCHANAN, in discussing the paper, stated that the blood picture of a myelogenous leukæmia tends to show a change towards the lymphatic type as the disease becomes more acute or towards the end of the life of the patient. He also pointed out that in a relapse subsequent to treatment by X-rays the blood was more lymphatic in character. The value of thyams as a hæmostatic was emphasised.

Dr. N. P. MARSH replied.

Mr. G. P. NEWBOLT read a short paper on

SOME CASES OF DISEASE AFFECTING THE PYLORUS AND NECESSITATING GASTRO-ENTEROSTOMY.

He related a number of interesting cases illustrating the various points raised in the paper.

Among other matters discussed was the difficulty of diagnosing the nature of certain growths even when exposed by the surgeon, and the importance of having a pathological report at the time of the first operation. He referred to the question of the value of pylorectomy, which, in his opinion, when undertaken for malignant disease, was almost always disastrous. He held a more favourable view of operations for palpable tumour of the stomach than was usual ten or fifteen years ago. He also related a case in which the hernia of the small intestine had taken place in the lesser omentum.

Mr. F. C. LARKIN, Mr. RUSHTON PARKER, Mr. K. MONSARRAT, Dr. NATHAN RAW and Mr T. C. LITLER JONES, discussed the paper.

Mr. G. P. NEWBOLT replied.

CENTRAL MIDWIVES BOARD.

Meeting held February 19th, 1914.

Sir Francis Champneys in the Chair.

A letter had been received from the Clerk of the Council transmitting a copy of correspondence between the Privy Council, the National Health Insurance Joint Committee, and the Carnarvonshire County Council in regard to midwifery practice by uncertified women in Carnarvonshire. This included a statement from a midwife that six uncertified women were practising in her district, to the detriment of her own work. The statement having been inquired into and verified by the local supervising authority, the Privy Council replied that it was an open infringement of the Midwives Act, and asked the Carnarvonshire County Council to take action against the offenders.

Respecting the Order issued by the Local Government Board requiring the notification of all cases of ophthalmia neonatorum, the Board agreed that the Local Government Board be asked whether, in respect to any future Orders proposed to be issued by them which affect in any way the duties of the Central Midwives Board or its Rules, a confidential draft could be laid before the Central Midwives Board for their consideration before it was finally settled. The Chairman was asked to confer with the Local Government Board or their principal medical officer on the ophthalmia Order just issued. Miss Paget pointed out that if she adhered to her rules the midwife could have no responsibility in a case of "purulent discharge," as before it reached that condition she would have placed the case under medical advice.

Explanations having been received, it was agreed that no further action be taken in the matter of the Norfolk County Inspector who had sent an unqualified person to inspect a midwife in her stead.

Correspondence between the Health Committee of Birkenhead and the Maternity Hospital there respecting a failure of duty on the part of one of the hospital staff had been laid before the Board. They agreed that the occurrence pointed to the reconsideration of rule E. 20 (5) at the next revision of the rules. In dealing with a letter from a certified midwife complaining of her suspension by the local supervising authority, it was agreed that the County Medical Officer of Health be reminded that no case of suspension which is not imposed by the proper authority, reported to the Board and recorded in its register could be upheld by the Board, and that the Central Midwives Board hoped that Rule F. would be remembered in dealing with such cases. It was further emphasised that the midwife must have *written* notice of suspension.

The draft report of the work of the Board during the past year was approved.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the seventeenth meeting of the Commission evidence was given by Dr. Coupland and Dr. Bond, Commissioners in Lunacy.

The witnesses stated that since 1876 the figures published by the Lunacy Commissioners showed a gradual rise in the recorded proportion of syphilitics admitted to asylums, but it could not be inferred that this increase denoted an increasing prevalence of syphilis, the increase shown might mean nothing beyond more thorough observation in respect to this particular. Throughout the whole period there has been a preponderance in the proportion of male cases in the private over that in the pauper class, and generally a similar but less markedly higher incidence in females of the pauper than in those of the private class. For the period 1908–12 the figures showed that of the male admissions 11.8 per cent. of the private cases and 8.7 per cent. of the pauper cases were syphilitics; for females the corresponding figures were 0.7 per cent. among private and 1.4 per cent. among pauper patients. Much variation in the degree of incidence appears in the inmates of different asylums, but speaking generally those institutions that receive inmates from industrial districts show higher ratios than those which deal mainly with an agricultural and rural community.

About 60 per cent. of the cases known to be syphilitic admitted in the period 1908–12 were general paralytics.

At the eighteenth meeting evidence was given by Sir Thomas Barlow, Bart., K.C.V.O., President of the Royal College of Physicians.

Sir Thomas dealt first with the importance of congenital syphilis and its effect as a hindrance to the birth-rate and to healthy development. He described how syphilis frequently manifests itself in the offspring of a woman affected by the disease, in producing first one or more miscarriages and afterwards children apparently healthy at birth, but sooner or later suffering from various affections. He stated that the life of these children at school, especially amongst the humbler classes, was most unpromising, and that many of them became perfectly useless members of society. He also drew attention to the fact that syphilitic infants are notably liable to convulsions, and that in these children the convulsions may inaugurate very serious diseases of the brain.

Sir Thomas next gave illustrations of the latency of the disease and pointed out the importance of realising how very widespread the damage caused by congenital syphilis may be, and that causes, for which no explanation can be given, may revive manifestations of congenital syphilis in many different situations.

He emphasised the importance in cases of this kind of maintaining continuous supervision of both parents and families. He considered that the ideal method of treatment and prophylaxis would be given a syphilitic infant, that both parents should be under medical supervision and medical inspection at frequent intervals, and other children of the family born subsequently should be inspected also at frequent intervals, and that this surveillance should continue for several years.

Sir Thomas said it was very difficult to estimate whether venereal diseases were less prevalent at the present time than formerly. He thought, however, that there was a general improvement in the morality of the population, and that the higher standard obtaining ought in time to produce less prevalence of the diseases. He thought it very hopeful for any educational crusade that might arise out of the work of the Commission, as the public mind was in a state of most promising preparedness to receive admonition and to recognise the moral obligation of these things being dealt with.

He was of opinion that special education or instruction on these subjects was very desirable. It might be begun possibly in the public schools, but certainly in the university period. More generally he thought that instruction should be given directly young people were sent to work.

In any educational measures he would urge that medical practitioners, and if possible family doctors, should be the backbone of the organisation. Besides the family doctor he thought that for young children the person to impart knowledge was the mother. He believed that something had been done in Western Canada in the way of special teaching to women of sexual conditions, and this teaching had been of a wholesome character and had been given without any offence whatever.

Sir Thomas was not in favour of notification of venereal diseases, and it was his opinion that there was much more to hope from general enlightenment and education. Apart from education he considered that what was required practically was the provision of facilities for effective and complete treatment in the early stages and the improvement of those facilities

to the utmost. He also advocated strongly the subsidisation by the Government of pathological research.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 28th, 1914.

APPENDICITIS.

APPENDICITIS ought to be one of the best known of abdominal affections, and consequently the easiest to treat if account be taken of the heap of literature devoted to the subject for the last twenty years. Yet a certain amount of obscurity persists in the minds of general practitioners (the first usually called in) as regards the treatment and diagnosis of the disease. Partisans of early and retarded interference are equally ardent in their respective views, and the question still remains unsettled. Is an immediate operation necessary in an attack of acute appendicitis of the ordinary type, or should medical treatment prevail until all symptoms of inflammation have subsided?

Dr. Temoin, of Bourges, read a paper at the Société de Chirurgie, wherein he stated that he always treated appendicitis as he would treat strangulated hernia; that is to say, he operated immediately the diagnosis was made.

Prof. Hartmann said he had followed the same practice for years.

M. Savariaud thought that early operation *(à chaud)* should be reserved for certain well-defined cases. Every patient should be operated upon immediately provided that the operation was without danger. Abstention was only advised where difficulties from ancient or recent adhesions are feared; where the attack dates already over thirty-six hours, or where the present attack has been preceded some weeks by another grave enough to create solid adhesions, and more especially a beginning of suppuration not yet absorbed. Immediate intervention should be the rule in a first attack, as secondary peritonitis, after all inflammation has disappeared, is much more grave than primary peritonitis. However, where the surgeon is called in several days after the *début*, the medical treatment should be continued to the end of the inflammatory process unless alarming symptoms indicate the contrary.

Prof. Delbet took an opposite view to the majority of his colleagues; he prefers abstaining during the acute period. His reasons militated in favour of expectancy. First, as regards the cicatrix. For the integrity of the abdominal wall it is better not to drain, yet drainage is the usual complement of immediate operation. Secondly, errors in diagnosis. The best clinicians have mistaken typhoid fever in the adult, and pneumonia with abdominal pain in the child for appenditicis, and here an operation might be followed by disastrous results. Thirdly, the danger of certain operations. There are cases where an operation is not only useless, but distinctly hurtful, especially in cases of appendicitis accompanied with icteric phenomena indicating hepatic intoxication, the appendicular vomito negro of Dieulafoy. In such cases an operation might be fatal to the patient, while an intelligent medical treatment would carry the patient over the crisis and put him in the best condition for subsequent operation *(à froid)*.

M. Delbet was met with the objection that perforation might take place, suddenly abolishing nearly all the chances of the patient. To this he replied that he could furnish his colleagues with the means of diagnosing in time either imminent peritoneal infection or perforation of the appendix before peritonitis set in. The first and most important sign was immobility of the diaphragm. In the normal condition a person respires with his diaphragm, and in the healthy individual the movements of the abdomen, and more especially the epigastrium, are much more active than those of the thorax. In patients, on the contrary, suffering from reaction of the peritoneum, the respiration is mainly effected by the thorax, the diaphragm does not act, the abdomen does not stir. This sign is easy to detect if the patient, lying on his back is examined in a good light. M. Delbet never found this symptom wanting; it can be observed at a very early date, before contraction of the abdominal wall is well characterised or any difference between the pulse and temperature is distinguished. It reveals invasion of the peritoneum and calls for immediate operation. Another case: The patient is being treated medically and all is going on well; pain has ceased. But some hours after the pain returns with its primary intensity; it may be relieved a second time, when a third attack recurs. Such painful iterative attacks constitute a certain premonitory sign of perforation or gangrene of the appendix and render an operation imperative. A third premonitory sign is furnished by the peritoneum. In a patient suffering from appendicitis with a certain amount of peritonitis localised to the right iliac fossa, the left side of the abdominal wall retains its usual elasticity. If it is depressed with the fingers right down to the left iliac fossa and suddenly released, one of two things will follow—either the patient will experience no disagreeable sensation, or he will complain of great pain and show his suffering by wincing. In the first case the peritonitis remains localised and is consequently amenable to medical treatment; in the second, the peritonitis has diffused and immediate operation is necessary.

Such are the principal signs worthy of attention. However, no pathological character, says Dr. Deroze, should be attributed to an isolated symptom in an affection as complex as appendicitis; the diagnosis is, after all, an affair of sound clinical examination. The patient should be seen at regular intervals—every six hours, for instance, and the result of each visit carefully compared with the preceding. The administration of opium is bad practice, as by masking the pain it lulls into confidence both attendant and patient.

Although this discussion has thrown some light on the treatment of appendicitis, nothing has been absolutely fixed; both parties maintain their positions, and perhaps it will be ever so.

GERMANY.

Berlin, Feb. 28th, 1914.

AT the Gesellschaft für Chirurgie the subject of

BLOOD DISEASES AND THEIR SURGICAL TREATMENT

came up for discussion.

Mr. Türk took up the subject from the standpoint of the physician and from three points of view—(1) What were the connections between the spleen and blood diseases? (2) In what clinical affection did the spleen participate actively? (3) What good was to be expected in these diseases from extirpation of the spleen? Formerly nothing was known of the functions of the spleen, and it was only through the history of development and biological investigation and the acquirement of knowledge of the internal secretions generally that light was thrown into the darkness. That there was a connection between the spleen and anæmic diseases, leucæmia, etc., was long known, but the most diverse views were held as to what that connection was. It was shown that in all probability there was no connection between the spleen and the formation of blood, but that on the other hand there was a connection between that organ and the disintegration of blood. The hæmolytic properties of splenic extract had not been explained. In hæmolytic icterus Eppinjer found narrowing of the lumen of central arteries and changes in the blood-vessels. Injury to medullary tissues could be brought about by toxic material, and also a splenogenetic injury to the blood had been determined. Over twenty years ago Banti had determined a form of disease in which anæmic changes accompanied a tumour of the spleen. He also proposed removal of the spleen, and found this had a curative influence. The anatomical foundation Banti laid down as fibrotic changes in the spleen, endophlebitis, secondary sclerotic changes in the liver,

damage to the bone marrow, and splenic noxa. The speaker arrived at a similar diagnosis in a case, as also did Hirschfeld and Klemperer. There might be two functions of the spleen—(1) hæmolysis, (2) hormones—which kept in check the hæmopoesis of the bone marrow. According to Banti, erythrolysis could be brought to a standstill by extirpation of the spleen. There was also another way that led to anæmia, and that was through hæmorrhages into the intestinal tract in connection with a large tumour of the spleen. The speaker had met with such a case in connection with infection of the umbilicus. Here extirpation of the spleen was difficult through dilatation of the blood-vessels. These were common foundation to the three following groups: (1) "family" hæmolysis, (2) acquired hæmolysis, and (3) pernicious anæmia. The first had been described by several as jaundice with excessive bile-colouring matter in the bowel, enlargement of the spleen, pains in the hepatic region, as in cholelithiasis, but complete absence of gall-stones, in the blood there was erythrolysis and polychromasy, bile pigment in the blood plasma with reduced persistence on the part of the erythrocytes. The excretion of bile pigment from the bowel exceeded the normal twenty times—0.12 to 0.15 per diem. Besides the "family" there were cases of acquired hæmolysis which might form the starting point of the family form of the disease. An enormous disintegration of the blood was the point in common, but the pathogenesis was not always the same. Whilst Minkowski looked upon the spleen as the offending organ, Banti held the enlargement of the spleen to be secondary. As, however, splenectomy resulted in clinical improvement, it might well be assumed that the spleen was at fault. It was also to be borne in mind that the resistance of the erythrocytes was diminished by chemical noxa. Lastly pernicious anæmia, which was not identical with the two former either ætiologically or pathologically. The blood itself was affected differently. Clinically the spleen showed less enlargement, it was in excess only in exceptional cases. If there was any injurious action of the spleen it was different from that in hæmolysis. Some other agent had to be assumed. Splenectomy here played a part, as had been proved by numerous authorities. The result obtained, however, was but transitory. Patient recovered rapidly at first from even what appeared to be a moribund condition, but the state of the blood never became normal again, as the speaker could prove by his later cases. The spleen here, therefore, was not the sole ætiological factor; it was a link in a chain which gave way after splenectomy.

Hr. Mühran said that all his cases had been cases of pernicious anæmia. In six of them operated on the homoglobin constituent of the blood increased, those in which there was no increase died. One died from purulent bronchitis, in two a hæmorrhagic diathesis was the cause of death, the fourth case suffered from myelitis, in the fifth case the degenerative character of the blood gradually went from bad to worse. Six patients, therefore, were still alive and in comparative health, but without being in good health. In all these cases the change in the blood for the better was undoubted, and their condition as regarded renewed strength had undergone improvement.

AUSTRIA.

Vienna, Feb. 28th, 1914.

Cancer and Radium.

At the Versammlung Deutscher Naturforscher und Aerzte, the subject of cancer and radium was again discussed in a communication brought forward by Dr. E. Wertheim. As he pointed out, the recent Congress at Halle had awakened great hopes for the treatment of cancer in female patients, and the general impression created was that we had entered on a new era in this domain of therapeutics. The management of the Krankenhaus had taken the laudable course of placing a large quantity of radium at their disposal, so that they were now in a position to subject such results to corroborative tests. It is a striking fact that not the slightest opposition was offered at Halle to the general view there expressed. Nevertheless, it was obvious that the conclusion there arrived at was but a momentary result which could not yet be regarded as finally established. For the production of the desired consummation, a new research had been opened, by the employment of large quantities of radium with effective filtration. As the task of preparing a report on the subject for presentation to the meeting had been entrusted to him, he chose, in addition to a series of cases so far advanced as to be inoperable, another series in which operation was still feasible. Such a choice afforded the only possibility of obtaining a definite result in a brief interval of time, as it was only in those cases in which subsequent operation—that is to say, removal of the diseased organ—was carried out, that the result of the radium treatment could be actually seen and a clear conclusion drawn. By a critical examination of the same, it becomes evident that a sufficient microscopic examination cannot be carried out to the requisite degree of complete exhaustiveness. Clinical observation must still be practised continuously for years, for Dr. Wertheim had himself often noticed in the microscopic examination of pieces removed from a diseased organ that the specimens thus observed presented varying pictures, the disease process sometimes appearing to be very favourably influenced and at other times but very slightly modified. Of the cases subjected to this special research, 19 were treated with radium and 3 with mesothorium. Of the 19 radium cases, 9 were operable, 9 others unmistakably inoperable, and 1 lay on the border line. Of the 9 operable cases, 2 could not be operated on after the radiation treatment had been employed, as this procedure had aggravated the condition to an extreme degree. The other 7 cases were operated on after being exposed to the radiations. The first of those was a very large cancerous growth; it shrivelled under the effects of the rays, and no nests of cancer cells were discoverable after the operation. The second was but little influenced. The third had been dealt with in the initial stage of growth—an opportunity of rare occurrence—and the result was perfect, no cancer cells being discoverable. The fourth was a large cauliflower tumour, and was treated for nine days with large doses of radium. The tumour dwindled down, but the patient's general condition gravely changed for the worse, emaciation proceeded rapidly and she died of peritonitis. Microscopic examination failed to reveal any cancerous structure. The fifth case was one of a large fungating tumour; the radium treatment, which was carried out with very large doses, gave a favourable clinical result, as the tumour shrank in the midst. But the microscope showed that the quantitative effect was practically nil; the cancer was still present. The sixth also showed a good result clinically; the cancerous growth diminished, but the microscope revealed cancer cell nests of which some were broken up and some arrested in growth. The seventh case was one of cancer of colossal growth. The clinical result was extraordinarily favourable. After four days' radiation treatment the tumour had disappeared, and the microscope showed only copious *débris* of cancer cells.

With regard to the border-line case, the cancer appeared diminished by the treatment, but a large swelling formed in the vicinity, and was accompanied by debility of so great degree that the patient could not be submitted to operation.

Of the nine inoperable cases, none presented any striking result from the radium treatment. It had been observed by some clinicians that previously inoperable cases became operable after radium treatment. And there can be no doubt that a corresponding result may be obtained also by other methods. We must not, however, conclude that the effects of radium are attributable to no other cause than the power which it possesses of cleansing foul cavities, as it is possible that we are also dealing with a specific influence. With regard to the three cases treated by mesothorium, the first was a cancer in the initial step, in which fresh cancer cells were still recognisable under the microscope. The second case was a far advanced one, and seemed clinically to be greatly improved by the treatment, so far as to appear favourable for operation;

but this procedure was declined by the patient. The third was one of a small tumour, which also dwindled down completely after operation, but nevertheless did not display under the microscope the conditions of complete evanescence.

The conclusions arrived at by Dr. Wertheim, after collecting all his clinical observations, were summarised in the statement that an influence on cancer was recognisable in all cases, both clinically and microscopically. Clinically, a dissolution of the tumour was observable in some cases, while in others there was merely aggravation of its growth. Microscopically, the known changes could be observed: the nuclei heaped up together, the cells dissolved. A complete cure could, then, be reasonably aimed at only when dealing with superficial cancer. He had arrived at the definite conviction that in those few cases in which the radium treatment had resulted in evanescence of cancer, the result was a merely trivial one, inasmuch as the same could be attained by the use of Paquelin's cautery, scraping, etc. A deep seated effect is surely forthcoming, but its degree is difficult to estimate and is nearly adways inadequate. According to the results of the experiments which he had hitherto carried out, a complete conquest of cancer by radium or mesothorium seems highly improbable. And nobody has yet pretended that radium produces a reduction of the affected lymphatic glands in the neighbourhood of the cancer. No far-reaching deep effects of the radium had been observed in any of Dr. Wertheim's cases; while, on the other hand, injurious results had appeared in several, some of which involved the whole organism, such as debility, emaciation, bodily weakness, pyrexia, agitation, sleeplessness; while others are of local manifestation: aggravation of the disease process, tissue necrosis, inflammation of the lower portion of the large intestine, etc. Doubtless those lesions will in time prove greatly reducible by the adoption of appropriate *technique*. But with the use of large doses it is not possible to avoid those ill-effects, even when a great deal is done in way of filtering the radiations. The impression had been made on him that operation proved more difficult after radium treatment. Obviously we must nevertheless proceed further with our clinical researches on radium and mesothorium, but with corresponding increase of precautionary methods. With regard to dosage, Dr. Wertheim inclines to the view that we must descend completely and permanently from the vast quantities, and that intervals of a greater number of days should be interposed in the course of the treatment. In no case should we be induced to discredit operative procedure, as this has hitherto proved to be the most effective method of cure. We should keep the fact always before our eyes that 50 per cent. of all women operated on have remained permanently cured. Thus it is possible to avoid injury to human life only by the adoption of a prudent course of procedure in the use of radium therapy.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH.

BRITISH MEDICAL ASSOCIATION.

A HIGHLY successful joint meeting of the Edinburgh, North of Scotland, and other Scottish branches was held in Edinburgh on February 27th. The time-table for the day began at 10 a.m., and the proceedings were terminated by a dinner in the Balmoral Hotel, under the presidency of Mr. C. W. Cathcart. Members of the Association were present from Inverness, Aberdeen, Dundee, and many of the country districts in Scotland, and the enjoyment of the evening was enhanced by Dr. Norie (Cardenden), Dr. W. Fordyce (Edinburgh), Mr. Cathcart, and others, who contributed song and story. During the day Mr. Scot Skirving gave a demonstration on modern methods for the treatment of syphilis, Dr. Graham Brown held a medical clinique, Dr. Sym gave a demonstration of eye cases, Dr. Turner demonstrated the uses of radium, and Dr. Hope Fowler gave a demonstration in the Electrical Department. Dermatological cases were shown by Dr. Norman Walker. All these were arranged for the forenoon; in the afternoon there was a clinical meeting in the large theatre of the Infirmary, at which Mr. John Fraser showed a case of transplantation of the fibula; Dr. R. A. Fleming, a case of tumour of the cerebello-pontine angle; Dr. Chalmers Watson, a case of diabetes. Mr. Scot Skirving, a patient after resection of the upper jaw for carcinoma; Dr. Dingwall Fordyce, a case of infantilism; Mr. Stiles, a boy after resection of the large intestine for Hirschsprung's disease, and a baby aged 1 year after nephrectomy for sarcoma; Dr. Graham Brown, a case resembling spinal progressive muscular atrophy in course of cure and other nervous cases; Prof. Alexis Thomson, a boy aged 14 suffering from paraplegia due to malignant disease of the spine; Dr. Gulland, several cases of blood disease; Dr. Edwin Bramwell, patient after decompression for glioma of the right frontal lobe; Mr. George Chiene, two abdominal cases; Mr. E. S. Carmichael, a baby after direct transfusion of blood from the father at three days old, for hæmorrhage neonatorum; Mr. Struthers, a patient after general peritonitis due to perforation of the pelvic colon, and a patient 14 months after cervical œsophagectomy; and Mr. Wilkie, a case of cirrhosis of the liver with hæmachromatosis, operated on for ascites by the performance of lateral anastomosis between two omental veins and two deep epigastric veins. After the clinical demonstration, a lecture on "Urinary Antiseptics" was delivered by Mr. J. Thomson Walker, F.R.C.S., London. A great number of interesting exhibits were on view in the museum, of which perhaps the most noteworthy were Mr. J. M. Graham's bloodvessels showing the result of primary suture, and Drs. J. S. Fraser and W. K. Milne Dickie's model of the middle and inner ear reconstructed from serial sections by the waxplate method, at a magnification of 20 diameters. A number of specimens of great pathological, medicolegal, and general clinical interest were also shown, as also drawings, skiagrams, apparatus, Folin's appliances for micro-chemical analyses, etc. The meeting was, altogether, one of the most successful that has been held in Edinburgh during recent years, and however much the association's influence may have waned of late, no one could but be impressed by the interest which the country members took in the proceedings and the friendly feelings which were evinced towards the association.

VICTORIA HOSPITAL FOR CONSUMPTION, EDINBURGH.

A draft agreement has been entered into by the Trustees of the Victoria Hospital and Dispensary and the Edinburgh Local Authorities administering the Public Health and Insurance Acts in connection with the care of tuberculosis, the preamble of which sets forth the status of the contracting parties and declares the desirability of amalgamating all the agencies in the city at present engaged in coping with tuberculosis. It is therefore agreed that the Royal Victoria Hospital, the Dispensary, and the Farm Colony shall be transferred to the Local Authority, the main considerations for the transfer being: (1) That the Victoria Hospital shall not, for a period of seven years, be used for advanced phthisis; (2) that the staff shall be taken over at not less than the existing rate of remuneration; (3) the creation of a Royal Victoria Hospital Trust for the continuance of one part of the function of the original dispensary—viz., the advancement of medical research, in so far as that is outside the province of the Local Authority, the rights of the Trust including the establishment, if they think fit, of a Chair or Lectureship in the University; (4) the existing teaching arrangements are to be carried on as before, and all reasonable facilities are to be afforded to the teachers or lecturer; (5) Sir Robert Philips' position in the Hospital and Dispensary to remain as in the past, so long as he holds the post of Consultant to the Local Authority. The agreement came before the Town Council on February 24th, and was remitted back for further consideration on the ground that this, being a scheme for taking over a voluntary institution, should not be entered into without due deliberation. There does not, how-

ever, appear to be any hostility to the scheme, and, one way or another, it is tolerably certain that the amalgamation of the hitherto voluntarily supported Victoria Hospital with the State-aided institutions and machinery for dealing with tuberculosis, will not be long postponed.

GLASGOW.

THE LATE DR. GARNETT WILSON.

DR. H. Garnett Wilson, of 5 St. James's Terrace, Glasgow, died at Annet Lodge, Skelmorlie, on 20th ult., at the age of 55. He had been ill for a considerable time. A native of Manchester, Dr. Wilson graduated in medicine at Edinburgh in 1882. For some years he was Resident Physician at Smedley's Hydropathic, Matlock Bridge, but he settled in Glasgow about 25 years ago, and soon acquired a large practice in the west end of the city. For some time he held the appointment of Physician to the Glasgow Hospital for Women. Dr. Wilson also took a deep interest in the work of various medical associations, and he was greatly valued as a friend by all the members of his profession with whom he came into contact. He is survived by his wife and two sons, one of whom, Dr. Haswell Wilson, is at present Assistant to the Professor of Pathology at the University of Glasgow.

GLASGOW MATERNITY HOSPITAL.

Lord Strathclyde, in presiding at the annual meeting of contributors to this hospital, and in moving the adoption of the Director's report, said that he was startled to observe, what no doubt might be familar enough to the medical profession, but what to ordinary laymen came with a shock of surprise, that close on one-third of all the women admitted to that hospital required exceptional surgical treatment, and he shuddered to reflect what would have their fate if they and their offspring had been left to chance and had not found the doors of that beneficent institution open for their reception. Lord Provost Stevenson, in seconding, referred to the question of maternity benefit, and said he understood that each case brought to the hospital cost the institution in food alone from 10s. to 15s., according to the time the women were in the buildings. When they found that the contributions of the approved societies amounted to only 3s. 9d. per case, they would agree, he said, that there was something far wrong, and he was glad to see that the various maternity hospitals were arranging for a conference on the subject. He was confident that they would find that the approved societies would look upon the whole matter sympathetically.

THE CARNEGIE TRUST AND THE UNIVERSITY OF GLASGOW.

The proposals just issued by the Carnegie Trustees for the Universities of Scotland show that, in the next five years, they propose to grant to the University of Glasgow £5,000 for the library and £45,000 towards provision of new buildings for the Faculty of Arts and the Department of Zoology. These grants are based on the system which the Trust has adopted of giving grants of capital to the Scottish Universities instead of additions to their incomes. The grant now to be made of £45,000 will be used, it is understood, in completing the western quadrangle of Glasgow University buildings by erecting its western side. Sir Donald MacAlister, at the late meeting of the Carnegie Trustees, said he desired very cordially, as representing Glasgow University, to acknowledge the manner in which the Trustees had met their desire for a capital grant. They fully entered, he said, into the spirit of the policy of the Trustees in limiting the grants to capital. Capital was difficult to get; income they thought they could secure.

POST-GRADUATE TEACHING IN GLASGOW.

In reference to some public correspondence which appeared about five months ago and to which reference was made at the time in the MEDICAL PRESS AND CIRCULAR, a meeting of the bodies interested in this subject has now been called for 6th inst. by Professor D. Noel Paton, Dean of the Medical Faculty of Glasgow University. The object of those summoning the meeting is to have a committee appointed, representative of the teaching bodies and hospitals interested in post-graduate teaching, to make arrangements for a general syllabus of lectures, to be delivered at times and places to suit the convenience of practitioners. Principal Sir Donald MacAlister will preside at the meeting on 6th inst.

BELFAST.

ULSTER MEDICAL SOCIETY.

A MEETING of the Ulster Medical Society was held in the Medical Institute on February 20th, the President, Mr. A. B. Mitchell in the chair. Professor Symmers read a paper on "Acute Pancreatitis." He had recently seen a number of sudden deaths due to this cause. In all these cases the patient had been an alcoholic. The stomach showed stippled patches and the pancreas was necrosed.

The paper gave rise to a good deal of discussion, and Professor Symmers was thanked for bringing forward a subject of such scientific and medico-legal importance.

Dr. J. E. MacIlwaine read a paper on "The Electro-cardiographic Method of Examining the Heart-beat." Dr. McIlwaine had been working with the new instrument recently installed in the Royal Victoria Hospital, and his experience went to show how important this method of diagnosis promised to be in the future. He projected a number of interesting cardiograms on the screen and explained the principles underlying the use of the instrument. He promised at a future meeting to bring forward a further series of cardiograms to illustrate the various forms of heart disease.

The meeting was very well attended, and those present showed their appreciation of the progressive action of the Board of Management of the Royal Victoria Hospital in placing this valuable means of diagnosis at the disposal of the profession in Belfast. During this session the attendance of the members at the meetings has up to the present been exceedingly encouraging to the President and those who have brought forward papers or interesting cases.

The President and Mrs. Mitchell are giving a reception at the Medical Institute on March 5th.

SAMARITAN HOSPITAL, BELFAST.

The annual meeting in connection with the Samaritan Hospital for Women was held on February 24th. The medical report states that during the year 1913 451 cases were treated in the out-patient department, and their attendances at the hospital numbered 1,384. In all cases treatment was given free, except to those who were able to pay for their medicine or any special appliances they required. In the wards 253 patients were treated. Of these 190 required surgical operations, 101 of these being major operations. During the year three patients died in hospital, two of them after operation. In consequence of the increasing work in the hospitals the Committee considered it advisable to appoint an assistant surgeon, and at their meeting in December Dr. W. R. McKenzie was unanimously selected to fill this position. Dr. McKenzie was trained under Dr. John Campbell, having assisted him in the hospital for almost three years. Dr. McKenzie is to be congratulated on this appointment to an institution which has trained a number of the foremost gynæcologists of Belfast in late years.

BELFAST MATERNITY HOSPITAL.

The annual meeting in connection with the Incorporated Maternity Hospital of Belfast was held on February 24th. The medical report stated that during the year 456 cases were treated in the hospital. There were 306 children born and 26 were still-born. There were 5 maternal deaths and 8 children died. The nurses attended 633 patients in their homes and 3,790 visits were paid to them. There were 641 children born, nine were still-born and there were three maternal deaths. In all 1,089 patients were treated in the wards and in the district with eight deaths, which represented a death-rate of only 8 per 1,000. The

Hospital had afforded excellent facilities to a considerable number of medical students and nurses for securing the best practical knowledge and training for their life work.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE NORMYL TREATMENT ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "Medical Temperance Reformer" is entirely mistaken. The Normyl Treatment Association, in spite of its not being kept in public view by advertisement, is still flourishing and continuing to rescue many downfallen and degraded people of both sexes every week. Your correspondent, with the narrow-mindedness of a pedant, betrays a complete ignorance of that which in some way or other appears to offend his dogmatic creed. He does not seek to ascertain the truth, but gives libellous currency to a report which he hopes will be damaging to the Association; but he carefully conceals his name, so that he may not be made to pay compensation for injuries which he may inflict. He ought to have known that neither Sir Owen Seaman nor I would have undertaken to promote the sale of this treatment if we had not first obtained the considered opinion of a leading physician that it was the best remedy for drunkenness which he knew, and that to make it generally known would be a work of benevolence which should result in great advantage to the State. The Association was started upon that foundation, and the opinion by which we were first guided has not only been confirmed by constant personal experience for more than ten years, but by the fact that the majority of our patients come to us upon the advice of their doctors, and that we number not less than 300 physicians and general practitioners among our customers. If doctors may be regarded as scientific, the Normyl treatment has been from the first submitted to the best scientific tribunal that I can think of for the purpose with the most satisfactory results. It will be objected, perhaps, that the doctors have not published their names, but that is entirely due to the etiquette of their profession, which very few care to offend. I respect their feelings in this matter, and your anonymous correspondent will hardly do otherwise. The truth is that the Normyl treatment is both a medical and a psychological treatment of great efficacy, but your correspondent, consciously I am afraid, desires to treat it as if it were put forward as magical. That is not claimed for it by the Association or by the many philanthropists and social workers who make use of it. What we contend for is that the result of our labours in the complete redemption of many human lives by use of this treatment is sufficient to justify our earnest endeavours to make it more widely known. The number of letters which we receive every week from people who have found lasting salvation by the use of it is so great that I am afraid an account of our stewardship such as your correspondent desires would mean something like a "Smile's Self-Help" in many volumes. It is pathetic that persons who call themselves reformers and possibly Christians should permit the word to escape them which could hinder the reformation of the most pitiable and most unhappy class in the community. Many of those who come to us have been treated by physicians in vain, and many have suffered long terms of detention in a reformatory for repeated drunkenness in public, and yet they have been able to save themselves by the Normyl treatment. Their testimony is beyond doubt. What your correspondent is probably knocking his head against is the idea that all patients who have come to us are said to have been permanently cured. We have never said so, nor have we allowed anybody else to say so on our behalf. Our proportion of successful treatments we believe to be greater than other people's, but we do not quarrel with other people for that reason. We are glad that they should be working successfully in the same field—there is plenty of room and much necessity for everybody to lend a hand. If your correspondent would attend a London Police Court for a month he would realise that in the cure of souls more perhaps than in anything else an ounce of practical experience is worth a ton of theory. Imprisonment, so far as I know, never does good to an inebriate; detention in an inebriate reformatory is almost invariably followed by reaction and an extra bad bout of drinking. The Normyl treatment, on the other hand, if conscientiously followed, invariably does good to the patient, and in many cases effects a lasting cure from the disease of alcoholism. Its cost is £3 3s., it is accompanied by no loss of liberty, and it is commonly followed by a recovery of self-respect and a return to work under ordinary conditions. To encourage such work as that is surely a thing to be proud of, and to discourage or hinder it a thing to be ashamed of by a reasonable or generous soul.

I am, Sir, yours truly,

CECIL CHAPMAN.

February 17th, 1914.

WHAT IS THE PROFESSION COMING TO?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—While passing along Holland Park Avenue on Thursday last I came across a convoy of sandwich men displaying large posters bearing the legend, "The Encyclopædia of Medicine, Part I., price sevenpence." It happened upon that morning that I had observed a conspicuous advertisement in bold type in the *Daily Telegraph*, describing what this encyclopædia was. The announcement contained a list of the contributors, comprising many leaders of the profession who should be safe from the clap-trap of common advertisements, and who must now bitterly regret having identified themselves with a medical work the exploitation of which for trade purposes has thus been lowered to the depths of an ethical procedure. Of what use to the profession are its ethical laws if to break one—and that the most jealously guarded—reduces, as in this instance, the profession to the level of a trade? We may acquit those upon whom the honour has been conferred of a displayed advertisement of their names in the advertising columns of the daily Press, assisted, indirectly, by the lowly sandwich men, of taking any intentional part in the commercial enterprise, so derogatory to their honour and dignity in respect of the means by which it is being exploited. At the same time I cannot help thinking that they are blameable in failing first to ascertain the use it was intended to make of their names.

I am, Sir, yours truly,

ANOTHER OBSCURE PRACTITIONER.

MEDICAL INCOMES AND THE NATIONAL INSURANCE ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your footnote appended to the letter of "An Old Radical" in the issue of the 18th inst. does not, I think, hit the nail on the head. Your contributor seemed to contend that hospital doctors had no right to demand or expect payment for attendance on panel patients, as the doctors were already remunerated by their superior position as consultants and specialists by being on the staffs of the hospitals. No one claims to be an universal specialist, but if panel doctors are not capable of diagnosing and properly treating ordinary cases of chest, digestive, skin and venereal disease, eye and women's and children's diseases, besides dozens of other specialities, his education was a sham and his licensing body a fraud. A second opinion and special treatment will always be required, and should be given on the initiative of the doctors in attendance, and this will give the hospital staffs their chance.

I am, Sir, yours truly,

JAMES HAMILTON.

60 Sydney Street, Chelsea.
February 28th, 1914.

Medical News in Brief.

The Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the above Society was held at 429 Strand, W.C., on Friday, February 20th, 1914, Dr. F. J. Allan in the chair. The principal business before this meeting was the consideration of the annual and quinquennial reports. These were duly approved and passed, the results in both cases being of a highly satisfactory nature. The claims for the month of January show a marked decrease and consequently a substantial margin in favour of the Society. The new and additional proposals both show a large increase on the same month last year, and the extra publicity now being given in this and other journals has already resulted in an increase of applicants. The Society has now been established for 30 years, having been started in March, 1884, and the sound basis on which it was founded and subsequently carried on has proved conclusively that one of the first and most important rules to establish is to restrict management expenses. The total sum paid away to members in the form of bonus since 1884 has now reached the sum of £19,000. This is in itself a convincing fact of the financial soundness of the Society.

A prospectus and all information may be obtained from Mr. Bertram Sutton, F.C.I.I., Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, W.C.

Miners and Doctors' Fees.

It is reported that a settlement has been arrived at between the medical men and miners in the Morningside district of Wishaw on the question of fees for medical attendance. The men, on the instruction of the Union, decided to reduce the fee from 2½d. to 2d. weekly, and the doctors gave notice of their refusal to give medical attendance unless at the old rate. A ballot of the miners took place, and by an overwhelming majority—360 to 72—they resoved to continue to pay to the medical men 2½d. per week. The decision, it is understood, affects all the country districts in Lanarkshire.

The Carnegie Trust.

The annual meeting of the Carnegie Trust was held in London on the 26th ult., Lord Elgin presiding. Reference was made to the proposal that Edinburgh University and the Royal Colleges of Physicians and Surgeons should inaugurate under their joint control a great Institute of Medical Research as a memorial to the connection of Lord Lister with the Edinburgh Medical School. It was proposed, he added, that in this institute the Royal College of Physicians' laboratory should be merged, and that provision should at the same time be made for University teaching in Pathology and Bacteriology.

The scheme has now been fully elaborated, and an appeal has been issued to the public for the necessary financial support. Through the assistance given by the Carnegie Trust in its third quinquennial distribution, the University of Edinburgh has been enabled to contribute a sum of £10,000, and the Royal Colleges are contributing a sum of £15,000 to inaugurate the memorial.

Medical Man's Death in a Cab.

An inquest was held on Monday last at the City Coroner's Court on the body of Rupert Edward Shaw Waddington, aged 27, Assistant Medical Officer of Health at Willesden, who died on Thursday while he was being conveyed in a cab to St. Bartholomew's Hospital.

Dr. R. H. Beardsley, of Grange-over-Sands, North Lancashire, stated that Dr. Waddington was his stepson. He was only appointed at Willesden three weeks ago. He had at one time been in a sanatorium for consumptives.

Dr. James Reginald Kemp, who lodged with Dr. Waddington, stated that the latter was very ill on Thursday, and after consulting Dr. Morley Fletcher, of St. Bartholomew's Hospital, the witness took him to the Hospital in a taxicab. He died on the way. The witness added that he believed Dr. Waddington has been inspecting school children, and had seen several cases of scarlet fever.

Dr. Bernard Spilsbury, who made a *post-mortem* examination, said there were some wounds on Dr. Waddington's right thigh, through which, he thought, the streptococcus was introduced. Death was due to heart failure following on acute blood poisoning set up by the germ, which might have been introduced in the handling of scarlet fever cases.

Dr. Morley Fletcher, who also gave evidence, agreed with Dr. Spilsbury, and the jury returned a verdict accordingly.

University of Cambridge.

At a Congregation held on February 27th the following degrees were conferred:—

M.B. and B.C.—G. N. Stathers, Trinity; W. A. Anderson, Clare; G. D. East, Emmanuel.

M.B.—E. S. Taylor, King's; M. Avent, Caius.

Notices to Correspondents, &c.

☞ **Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Persimmon.—The term "albumen" is now confined to describe the chief constituent of the white of egg; "albumin" to this

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

M.R.C.S., L.R.C.P. (Leeds).—A book which can be highly recommended is "Anæsthesia and Analgesia," by Dr. J. D. Mortimer, published by the University of London Press, price 6s. net.

M.B., F.R.C.S. Edin.—Our correspondent has done all that is necessary under the circumstances. The incident was due to an inadvertence, for which he is not to be held responsible.

R. M. O.—Hæmogoblin, a slightly manganised colloid of iron, is an example of the colloidal state occurring naturally in the body.

"AS OTHERS SEE US."

"There can be, indeed, little doubt that in every respect the Seventeenth International Medical Congress made a record which will severely tax the resources of any other community to surpass or even to approach. If any complaint could be formulated at all it was that of an *embarras de riches* of hospitality."—*American Medicine.*

Spes.—A quantitative analysis of the urea should always be regularly made in pregnant women in whom headache, restlessness, and œdema of the eyelids are present, suggestive of impending eclampsia. Any excess of urea which may be found is of higher significance than the presence of albumen, while the absence of albumen might lead to an error in diagnosis.

Dr. T. B. (Bournemouth).—The question is one which our correspondent should submit to his solicitor.

Dr. A. C. R. (S. Wales).—Some evidence has now accumulated in favour of the view that erythema nodosum is related to tuberculosis, and the condition has been described by French observers as "pre-tuberculous."

Meetings of the Societies, Lectures, &c.

Wednesday, March 4th.

Medical Society of London (Whitehall Rooms, Hotel Metropole, W.C.).—7.30 p.m.: Anniversary Dinner.

Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.).—5 p.m.: Arris and Gale Lectures:—Dr. F. Wood Jones: The Morphology of the External Genitalia of the Mammals. (Lectures I. and II.)

Royal Society of Medicine (Section of the History of Medicine) (1 Wimpole Street, W.).—5 p.m.: Mr. Wm. Buckler

and Professor R. Caton will show: (1) A Find of Surgical Instruments recently made at Colophon in Asia Minor; (2) Collection of Greek and Roman Surgical Instruments made by the late Dr. J. Stewart Milne. Dr. Dan McKenzie: Healing Wells and Waters, with a Suggestion as to the Origin of the Votive Offering (illustrated). Dr. Parkes Weber: Art and Epigram in Science and Medicine in Relation to Death (illustrated). Mr. Glanvill Corney, I.S.O.: Some Physiological Phantasies of Third Century Repute. Dr. Fielding H. Garrison: A Relic of the King's Evil in the Surgeon-General's Library (Washington, D.C.).

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY, SECTION OF OPHTHALMOLOGY, SECTION OF OTOLOGY) (Combined Meeting) (1 Wimpole Street, W.).—8.30 p.m.: Discussion on Nystagmus, will be re-opened by Dr. Llewellyn, and Dr. Dan McKenzie, Dr. Wilfred Harris, Dr. S. A. K. Wilson, and others will speak).

THURSDAY, MARCH 5TH.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Address:—Dr. A. E. Giles: Meditations Based on 1,000 Abdominal Operations at the Prince of Wales's Hospital.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Epidiascope Demonstration by Dr. Louis W. Sambon.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Paper: Dr. J. Barnes Burt (Buxton): The Production of Osteophytes and Exostoses in Chronic Gout and Arthritis Deformans (illustrated by X-Ray Photographs and Pathological Specimens).

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m.:—Specimens by T. G. Stevens, Dr. Cuthbert Lockyer, Dr. Victor Bonney, Dr. Drummond Maxwell. Short Communications by Dr. Herbert Williamson and Dr. Charles Noon, Dr. J. Barris. Paper: Dr. T. W. Eden: A Case of Superior Recto-vaginal Fistula dealt with by an Abdominal Operation after Preliminary Colostomy, with Remarks on the Operative Treatment of this Condition.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Dockrell: Ulerythema—I., Aphryogenes; II., Centrifugum; III., Syeosiformis.

FRIDAY, MARCH 6TH

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Mr. H. J. Davis, Mr. W. Stuart-Low, and others. (The set discussion on, and exhibition of cases illustrating, Intranasal Treatment of the Frontal Sinusitis will be held on April 3rd. The discussion will be opened by Dr. Watson Williams and Mr. Herbert Tilley.)

ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Discussion on Posture in Relation to General Anæsthesia (opened by Dr. W. J. McCardie). Sir Frederick Hewitt, M.V.O., Mr. E. B. Waggett, Mr. Douglas Harmer, Mr. Ivor Back, Mr. Harold Barwell, and others, will take part.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Arris and Gale Lectures:—Dr. F. Wood Jones: The Morphology of the External Genitalia of the Mammals. (Lectures I. and II.)

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8. p.m.: Cases. 8.30 p.m.: Paper by Dr. Harry Campbell: The Treatment of Syphilis of the Central Nervous System.

MONDAY, MARCH 9TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on Radium Therapy, to be introduced by Mr. Hayward Pinch, followed by Sir Frederick Treves, Bart., G.C.V.O., Sir Alfred Pearce Gould, K.C.V.O., Mr. A. Clifford Morson, Mr. Herbert Williamson, Mr. T. H. Kellock, Mr. Douglas Harmer, Dr. Finzi, Dr. Dawson Turner, and Dr. Lewis Jones.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lecture:—Professor C. Mansell Moulin, M.A., M.D., F.R.C.S.: Observations on the Biology of Tumours.

TUESDAY, MARCH 10TH.

ROYAL SANITARY INSTITUTE.—7.30 p.m.: A Discussion will take place on Social Conditions in Relation to Public Health, to be opened by Papers on The Prevention of Tuberculosis from the Social Side, by Hilda Clark, M.B., and on the Social Aspect of the Housing Question, by F. E. Fremantle, M.A., M.B., F.R.C.P., County M.O.H., Hertfordshire. Chair will be taken at 7.30 p.m. by Waldorf Astor, M.P.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY) (1 Wimpole Street, W.).—5.30 p.m.: Paper: Mr. Herbert J. Patterson: Gastro-jejunostomy: The Principles which should Determine Its Application and the Indications for Its Use.

ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY) (1 Wimpole Street, W.).—8.30 p.m.: Joint Meeting with British Psychological Society: Mr. W. McDougall, F.R.S.: The Definition of the Sexual Instinct. Dr. H. Devine: The Biological Significance of Delusions.

Appointments.

CARLILL, HILDRED B., M.D.Cantab., M.R.C.P.Lond., Physician to Out-patients at the City of London Hospital for Diseases of the Chest.

DAVIDSON, H., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Teddington District of the County of Middlesex.

GILL, D. M., M.B., C.M.Aberd., Medical Officer to the Fleetwood Council.

HAMILTON, Captain A. F., I.M.S., Clinical Assistant at the Chelsea Hospital for Women.

MCCOWEN, Major W. T., I.M.S., Clinical Assistant at the Chelsea Hospital for Women.

O'SULLIVAN, J. E., L.R.C.P. & S.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Charlestown District of the Country of Mayo.

WALSH, J., Medical Officer to the Midleton Union Hospital, Cork.

WHITE, HILL WILSON, M.B., B.Ch., B.A.O.Nat.Univ.Irel., L.M. Rotunda. Assistant Medical Superintendent at the Paddington Infirmary, W.

Vacancies.

Stockport Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, washing, and residence. Applications to the Secretary.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Royal Free Hospital, Gray's Inn Road, W.C.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence and washing. Applications to the Secretary.

Lancashire County Asylum, Winwick, Warrington.—Pathologist and Assistant Medical Officer. Salary £250 per annum, with board, furnished partments, attendance, and washing. Applications to the Medical Superintendent.

Rochdale Infirmary.—Senior House Surgeon. Salary £110 per annum, with board, residence, and laundry. Aplications to T. Elvyn Kershaw, Secretary.

Birmingham General Dispensary.—Resident Medical Officer. Salary £220 per annum, with furnished apartments, fire, light, and attendance. Applications to Ernest W. Forrest, Secretary, 32 Union Street.

Births.

GUTHRIE.—On Feb. 27th, at 2 Woodland Road, Rock Ferry, Cheshire, the wife of Thomas Mansfield Guthrie, M.B., of a daughter.

HODDER.—On Feb. 23rd, at 21 Foregate Street, Stafford, to Dr. and Mrs. A. E. Hodder, a daughter.

STEPHENSON.—On Feb. 21st, at 60 Prince of Wales Road, Battersea Park, S.W., to Gladys, wife of Humphrey Stephenson, M.R.C.S., L.R.C.P., a son.

WHARTON.—On Feb. 21st, at 102 King Street, Oldham, to Dr. and Mrs. Alwyn Wharton, a daughter.

WILLIAMSON.—On Feb. 25th, at 10 Camp Terrace, North Shields, to Dr. and Mrs. J. Burrell Williamson, a son.

Marriages.

GILLIATT—KANN.—On Feb. 24th, at Weybridge, William Gilliatt, M.S., F.R.C.S., of 58a Wimpole Street, W., to Anne Louise, eldest daughter of John Kann, of Lyne Hill House, Chertsey, Surrey.

HOSFORD—COLEMAN.—On Feb. 28th, at St. John's, Hove, J. Stroud Hosford, F.R.C.S.Edin., to May, daughter of the late Mr. W. Coleman, of Runhall, Norfolk.

JEFFERSON—FLUMERFELT.—On Jan 17th, at Victoria, B.C., Geoffrey Jefferson, M.S., F.R.C.S., elder son of Dr. and Mrs. Arthur Jefferson, of Rochdale, Lancs., to Dr. Gertrude Flumerfelt, daughter of Mr. and Mrs. Flumerfelt, of Ruhebühne, Victoria, B.C.

JUETT—GRIERSON.—On Feb. 26th, at St. George's Cathedral, Perth, W.A., Alex. Juett, B.M., B.Ch., youngest son of Mr. and Mrs. Juett, of Western Australia, to Ida, second daughter of Mr. and Mrs. C. J. Grierson, of Warwick Road, Ealing, formerly of Queensland and Brazil.

MACKINNON—WILLIAMS.—On Feb. 25th, at Marylebone Parish Church, Daniel Mackinnon, M.B., Ch.B., D.P.H., of Lagos, Nigeria, younger son of the late Donald Mackinnon and of Mrs. Mackinnon, Murraybank, Murrayfield, Mid Lothian, to Jessie, widow of the late Arthur Williams, 6 Albion Street, London, W.

RIX—WAGSTAFF.—On Feb. 23rd, at the Parish Church, Berkhamsted, Herts, Rowland Waters Rix, F.R.C.S., son of J. A. Rix, Esq., of Gillingham, Kent, to Marjorie Edith, younger daughter of Philip Wagstaff, of Berkhamsted.

Deaths.

ASHMORE-NOAKES.—On Tuesday, Feb. 24th, at 11 Morpeth Mansions, Dr. S. S. Ashmore-Noakes, after a long and painful illness.

HAYDON.—On Feb. 23rd, at The Empire Hospital, Vincent Square, Ada, wife of Arthur Haydon, M.D., of 50 Pembroke Crescent, Hove.

MAIN.—On Feb. 24th, at Thornbrae, Alnwick, Alexander James Main, M.D.Edin., L.R.C.S.

MOORE.—On Feb. 27th at "Penlea," Shirehampton, Bristol, George Moore, Deputy Inspector-General of Hospitals and Fleets, R.N., retired, aged 86.

STEWART.—Donald Stewart, M.D., of The Prebendal, Aylesbury, and late of Nottingham, in his 72nd year.

WILLIAMS.—On Feb. 25, at Sydenham House, Harrogate, Annie, wife of Dr. Neville Williams.

WILLIAMS.—On Feb. 25th, at 6 Brunswick Place, Southampton, Edward Hanbury Williams, Fleet Surgeon, R.N. (retired), aged 60.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, MARCH 11, 1914. No. 10.

NOTES AND COMMENTS.

Dr. Chapple and the London Hospital.

THE question of registration of nurses has been raised in the Commons by Dr. Chapple, who brought forward a Bill on the subject. His advocacy was marred by a bitter and altogether uncalled for attack on the London Hospital, and for this he was manfully called to order by the Speaker. It must be obvious to the least trained politician that no cause, however strong, will hardly be furthered by introducing a side issue of that kind. In short, Dr. Chapple, by indulging in his uncalled for hostilities, *ipso facto* admits the weakness of his own cause—namely, the official registration of nurses. Despite the powerful and consistent advocacy of that step in certain quarters, there are not wanting reasons to indicate that its consummation would be a disaster, not only to the nursing profession, but also the public, who want sick nurses pure and simple, not women stuffed with theories and with a useless load of high standard nursing literature. There are many subjects which it is essential that a nurse should know if she is to discharge her duties with intelligence. To demand from her more than the elementary knowledge of anatomy, physiology and medicine is, in most cases, to render her a dangerous nuisance rather than an invaluable ally and helper to the medical man. A little knowledge is a dangerous thing, and it is rendered none the less dangerous when exacted under the plea of raised standards and of registration.

High Standard Nursing Examinations.

THE attack upon the "London" appears to have been based upon two main points—namely, the shortness of the training period, and the fact that nurses were sent out to private patients and a profit made thereby for the hospital. As to the two years' training, it may or may not be sufficient for the purpose of transforming a raw probationer into a competent nurse. Possibly the average woman would require a longer period of training, but then comes the question of the sort of training Dr. Chapple has in mind. If he wishes a nurse to pass high standard examinations five or six years would barely suffice. Some of the questions set to nurses in examination papers might well "floor" an advanced student ready for his final examinations. We submit that this sort of thing is simply farcical. The evil appears to spring from the advanced nature of the lectures delivered at the hospitals by ardent young men on the staffs, whose science has not yet been tempered by practice. A glance through the lists of books prepared for nurses confirms the impression that a serious attempt is being made to create a new sort of hybrid medical nurse practitioner in much the same way that the nurse-midwife—another pseudo-practitioner—has been forced into the legitimate domain of medicine. As to profits made out of nurses, if Dr. Chapple is anxious to act as their champion on that score he will find abundant opportunities in a thousand places other than the London Hospital. A little wholesome discussion of the whole question in its broader aspects might lend more wisdom and less temerity to his advocacy.

The Poor Law and National Insurance.

SOME weeks ago Mr. Felix Cassell, in the House of Commons, asked the Secretary of the Treasury whether his attention had been called to the fact that about 2,000 insured persons were in receipt of Poor Law relief. In reply, Mr. Wedgwood Benn questioned the figures, and said he knew no trustworthy source from which such statistics could be drawn. Mr. Cassell further asked whether a number of consumptives in workhouse infirmaries would be paid for by the Government. Mr. Benn's answer was concise. He said it was not open to Insurance Committees under the Act to make arrangements with, or payments to, Poor Law authorities for the treatment of tuberculous insured persons in Poor Law institutions. This candid admission lets the cat out of the official bag with startling effect. The Insurance Commissioners, being unable to provide for the efficient treatment of tuberculosis, institutional and otherwise, are obtaining gratuitous help of the Poor Law medical service, both in and out-door, in dealing with consumptives. The economic aspect of this transaction is somewhat serious. This shifting of responsibility means that the nation is paying for the treatment of tuberculosis indirectly through the Poor Law, as well as directly through the Insurance Act. The bill presented by the Insurance Commissioners for medical benefits and sanatorium treatment is therefore misleading. It deals with a portion only of the tuberculous, while the rest are handed over to the Poor Law or to the voluntary medical charities, in either case to be paid for out of funds other than those raised for the purpose of the Insurance Act. There is a certain obliquity about the transaction that does not commend itself to the plain man, who expects the Government to stick to their bargain. Then, again, what about the voluntary charities?

Free Aid from Voluntary Hospitals.

FOR the Insurance Commissioners are receiving a vast amount of help from the voluntary medical charities of the United Kingdom. Day after day immense numbers of insured persons are receiving first-class advice and treatment from the general and special hospitals, both as in and as out-patients. No money is paid by the Government for this medical service to insured persons, although

it is clearly essential to the conduct of any adequate scheme of national benefit. In this instance the philanthropic public is being taken advantage of by the Insurance Commissioners, who pay not a penny to the hospitals for services they are statutorily bound to provide and pay for. The Government, with true departmental casuistry, seek to modify their refusal to indemnify the hospitals by adding that it is open to Insurance Commissioners to make what provision they consider necessary for the insured persons in their area. That sounds well in the Commons, but it would carry greater weight were Mr. Wedgwood Benn to say how many hospitals had received payment in the manner indicated. As a matter of fact, a large amount of tuberculosis is being at the present moment treated in skin, eye, orthopædic, and other special hospitals. Why should the hospitals and the consultant medical staffs not be paid for services under the Act? In some cases within our knowledge certificates have been obtained from hospital surgeons and physicians for obtaining sick pay under the Act, but not a penny has been paid for that indispensable service. It is to be hoped that attention will be given to these anomalies without waiting for the tedious process of inquiry that has been promised some years hence.

Out-patients and Operations.

FROM time to time we are reminded by unfortunate "incidents" that hospital organisation has not yet attained an ideal of perfection. Not a few of these happenings are attributable to errors of judgment on the part of resident medical officers in sending away patients whose condition should have indicated indoor treatment. Now and then, of course, some cases of the kind must elude any sort of system, but the margin of individual error depends, more or less, on such circumstances as the number of patients, the adequacy of in and out patient staffs, beds at disposal, and so on. When a hospital is fairly free from what the journalists delight in describing as "remarkable allegations" or "scandals," it may be concluded that anything of the kind falls under the "unavoidable" heading. In a well-managed institution, like the West Ham Hospital, one would hardly expect a patient to be sent home a few hours after the amputation of a toe, yet that is what actually occurred. An inquest was held at the local Poor Law Infirmary on the body of a man of 60, who died of sepsis and diabetic gangrene. It appears that deceased was an out-patient of the hospital and was advised to have his leg amputated high up. This he refused: his toe was then amputated and the patient, after an interval of five hours, was sent home, apparently alone and still suffering from the effects of the anæsthetic. The Medical Officer saw him "a day or two later," and advised him to go to the local infirmary, where he was taken in five days after the operation and died in about three weeks. There can be no reasonable doubt that the ultimate result would have been the same had any other course been adopted. Hospitals, however, are provided for the relief of suffering folk, and it would be not easy to imagine a more urgent case than that of a diabetic suffering from gangrene of the foot.

A Play to Teach Sex Hygiene.

A NEW departure in play production was witnessed the other day at the Little Theatre, when M. Eugene Brieux's "Damaged Goods" ("Les Avariés") was presented in English by the Authors' Producing Society, under the auspices of the Society for Race Betterment. The play with a purpose has existed, of course, from time immemorial, and none will deny the value of histrionic art as a means of imparting useful lessons which might not readily be learned in any other way. There is no mincing of matters by Mr. Pollock, the translator of the play in question, and a spade is called a spade. Frankly, the object of the piece is to instruct the public into the dangers attendant upon sexual vice and the ravages wrought by syphilis in particular. To the manner in which the performance was presented no exception can be taken, while it must be admitted that, as a commentary upon the increasing public interest with regard to venereal disease, the play could hardly be more didactic than it is. After all, the public must be taught somehow or other the dangers of syphilis and the means for its prevention if any practical good is to result from the present Royal Commission. It would be a good thing, therefore, if the play were allowed fuller opportunities to appeal to the very classes of the community for whom its teachings are designed.

LEADING ARTICLES.

THE NORMYL "CURE" FOR INEBRIETY.

I.

THE craving of the man in the street for specific remedies is largely responsible for the vast industry that deals in secret remedies. In extreme instances he believes that there is one medicine, say, for measles and another for small-pox, while every other disease has its appropriate drug. Where legitimate medicine fails to provide the means of cure he turns to the proprietor of secret remedies for succour. The revelations of the somewhat apathetic Select Committee upon the subject have partly revealed the merits of the average preparation sold under the ægis of a patent medicine stamp. Amongst the morbid conditions that work havoc amongst human beings there is hardly one that is less amenable to present methods of scientific treatment, and therefore more open to the operations of the secret remedy proprietor, than that of inebriety. A large number of drug preparations and of "systems" of treatment are in the market, many of them of transatlantic origin. Analyses have been published of many of these so-called remedies, which are usually of a costly nature. They have been found to contain in some cases harmless ingredients that could not conceivably produce the least effect upon a moral failing like drunkenness. Potassium bromide figures in several. A large number contain powerful alkaloids, such as strychnine, atropine, hyoscyamine, hyoscin, duboisine and homatropine. The sale of such drugs without due description on the label in itself forms a scathing commentary on the patent medicine law. The stupidity of the whole system may be set forth in the assertion that inebriety is not curable by any drug or combination of drugs known to medical science. In a few instances male inebriates may retain sufficient strength of will to shake off the fatal habit into which they have fallen. So rare is reclamation amongst female inebriates that a well-authenticated case recorded a few years ago by a

physician in West London attracted much attention in medical circles. It is evident, therefore, that anyone professing to have a cure for inebriety is claiming to have a knowledge and to possess remedies outside the range of modern medical science. With this preface, we will turn to the consideration of the Normyl Treatment Association, founded for the purposes of treating inebriety. A long letter in defence of the methods of that body appeared in the correspondence columns of our last issue. It is not the first time we have criticised this particular organisation, but so impressed have we been with the transparent *bona fides* of the writer that we have made some further inquiries into the working of the Association. Enquiry at Somerset House showed that the Company does not issue any invitation to the public to subscribe any part of its nominal capital of £1,000. The only shares issued, seven in number, were taken up by Sir Owen Seaman (Editor of *Punch*), Mr. Cecil Chapman (the London Police magistrate), the Rev. Hugh Chapman, Mr. Charles B. Gregory (a solicitor), Mr. Louis Frere (accountant), and Messrs. Archibald White and E. B. Lovelace. These gentlemen apparently did not pay for their shares, as the published accounts show: "7 shares of £1 each, less calls unpaid, £7." At the same time there is a return of annual subscriptions and donations amounting to an average of rather over £50. The honorary secretary of the Association is the Reverend Hugh Chapman, and it will be of great interest to learn from himself and his colleagues on what grounds they have persuaded themselves of the absolute accuracy of the curative claims of the "treatment" they are offering to the public. The object of the company concerned, as set forth in the articles of association, is to bring before the public the "Hutton Dixon antidote and any other medicine or treatment for cure of drunkenness." The last proviso suggests that the Association were not altogether convinced that Mr. Hutton Dixon had said the last word in the attempt to deal with an acknowledged curse of society. Some enlightenment as to the scores of remedies that have been exploited for this purpose may be gleaned from the book "Secret Remedies," published by the British Medical Association, and another by the American Medical Association, not to mention the startling disclosures contained in the "Australian Report on Secret Drugs (1907)." On referring to the last-named volume, we find, on page 172, the reproduction of a Normyl advertisement in an Australian paper, in which the following names are given as being on the English committee:—The Archbishop of Westminster (Dr. Bourne), the Archbishop of Armagh, the Bishop of Chichester, the Bishop of Southwark and the Rev. Canon Scott-Holland. In a subsequent article we propose to discuss further the terms of the advertisement to which these names are appended. Meanwhile, it suffices our present purpose to show that the claims of the Normyl treatment are supported by various prominent public men, whose character and good faith are above suspicion. To the names already mentioned may be added that of Watson Armstrong (Baron), who joined the Association in 1907. The issue before us is comparatively simple. Either these worthy and distinguished men are wrong in supporting Normyl, or the medical profession is wrong in ignoring Normyl. It can hardly be that men of the standing mentioned have surrendered to the mere clap-trap of a proprietary remedy agent without a serious attempt to investigate his claims. Examination of this subject involves various vital and delicate issues between the promptings of philanthropy, the never-ending fallacies of the scientifically untrained mind, and the unresting inroad of commercialism into the domain of legitimate medicine. The matter is somewhat tangled, but we hope to draw attention to some of its salient points in the course of a few brief articles, as the Normyl Association presents an excellent illustration of the struggle that has been going on for three hundred years or more between the proprietors of secret remedies and the upholders of State-guaranteed orthodox medicine.

CURRENT TOPICS.

Typhoid an Accident.

In this column we published last week an article dealing with the meaning of words. One of the most difficult words to define is "accident"; for proof of this we need only call to mind the diversity of opinions expressed in cases brought before the Courts under the Workmen's Compensation Act. The word "accident" is apparently of wider application than most of us know. If we take a common definition and say that an accident is an event that takes place without one's foresight or expectation, there is no end to the accidents to which employees are exposed, and for which employers would have to pay compensation. In a case recently brought before the Courts in Dublin, it was contended that a labourer in the employment of a board of guardians had met with an accident in contracting typhoid fever. The man was employed as machinery attendant at a workhouse, and in the course of his work he had occasionally to descend into a sewage pit in order to clear away obstructions to the outflow of sewage. A few days after his last descent he developed typhoid fever, and some time later succumbed to that disease. There can be little doubt that the labourer did not expect the typhoid bacillus to enter his system, nor did his foresight warn him of his danger. In fact, accident, according to the above definition, plays a most important part in our daily lives; we live by accident, by accident we die. Our success and our failure are brought about by the same cause. We are at every turning subject to fate, chance, or the "blind action of stupid matter." There can be little doubt in the present state of our knowledge that infection by any organism is of all the work of stupid matter the blindest. In delivering judgment in the above case the Lord Chancellor held that, as no evidence had been given as to the time and place, when and where the labourer contracted the disease, it could not be maintained that the accident arose in the course of the man's employment.

The Life-History of the Flea.

FROM the public health standpoint, one of the most important discoveries of recent years is that of the transmission of plague bacilli by certain of the lower animals and by insects. On epidemiological grounds the theory of conveyance by fleas was arrived at by Ogata in 1897, since when numerous experiments have been made to determine the exact mechanism of infection from this source. In the Eighth Report on Plague Investigations in India, issued as the Third Plague Supplement to the *Journal of Hygiene*, the results of some observations by Mr. A. W. Bacot and Dr. C. J. Martin, of the Lister Institute, into the methods of transmission of the *B. pestis* are given. They found that under conditions precluding the possibility of infection by dejecta, two species of rat-fleas, *Xenopsylla cheopis* and *Ceratophyllus fasciatus*, fed upon septicæmic blood, can transmit plague during the act of sucking, and that certain individuals suffering from a temporary obstruction at the entrance to the stomach were responsible for most of the infections obtained, and probably for all. The various stages in the life-history of five varieties of fleas have been carefully studied, and it is interesting to note that the possible length of life of an individual flea from the egg until death varies from 376 to 966 days. It is estimated that the common *Pulex irritans* may remain alive apart from any host for 19 months, the rat-fleas surviving for about the same period. For killing fleas in all stages, naphthalene is recommended as a suitable and efficient parasiticide. Camphor is equally good, but more expensive than naphthalene, while benzine vapour is uncertain in its action.

The Operative Treatment of Fractures.

A COMPARISON of the modern methods of treating a broken bone with those in vogue a quarter of a century ago shows that quite a revolution has taken place in surgical art with regard to the management of fractures in general. Thanks to the labours of men like Bardenheuer, Lucas-Championnière and Lane, the evil effects of prolonged immobilisation, and the beneficial results obtained by the open operation, have been amply demonstrated. According to Professor Ernest W. Hey Groves, M.S., F.R.C.S., of Bristol, in his Hunterian Lectures on "The Experimental Principles of the Operative Treatment of Fractures and their Clinical Application," recently delivered before the Royal College of Surgeons of England, a preliminary six months' training in a carpenter's shop and the performance of a certain number of experiments upon the broken limbs of animals would endue surgeons with such manual dexterity that we should see and hear far less than we do now of operative failures. Professor Groves has carried out a number of such experiments upon the femora and tibiæ of cats and rabbits, the results of which show beyond question the supreme importance of efficient mechanical fixation. Such a union is best carried out by the use of a long plate applied to the bone and fixed with cotter pins which go through the whole thickness of the bone, being kept in place by a nut. In animals treated according to this method union took place without excessive callus-formation and they were enabled to use the leg freely from a week to a fortnight after the operation. The method of indirect fracture fixation, as practised by Professor Groves, with the asistance of bolted or screwed plates, has given excellent results in human beings, and, where operation is called for, it appears to constitute a distinct advance in our treatment of a troublesome and incapacitating class of injuries.

The Wassermann Reaction in Nervous Diseases.

THE recent researches of Noguchi and others in connection with the finding of the organism of syphilis in general paralysis have given an added impetus to the investigation of the behaviour of the Wassermann test in diseases of the nervous system in general. Thus, in locomoter ataxy the reaction is positive both in the serum and also in the cerebro-spinal fluid, unless treatment has been vigorous. An exhaustive summary, the result of a lengthy research, of the condition of the Wasserman reaction and its application to neurology is given in a recent number of *Brain* by Drs. Paul Fildes and James McIntosh, of the London Hospital. They point out that the practical value of a "provocative" injection of salvarsan lies in its intentional application in order to produce a positive reaction in a case of suspected syphilis in which it was previously negative. The view hitherto held that if a patient with a negative reaction, known to have had syphilis previously, does not show an exacerbation of the Wassermann reaction as a result of an injection of salvarsan—*i.e.*, in which the injection is not "provocative"—he may be looked upon as cured, is regarded by these observers as having insufficient foundation, for it does not preclude the possibility of an exacerbation or relapse of syphilis at an early date. The reaction is apt to be negative in the serum or the cerebro-spinal fluid in hemiplegia, old lesions of the nervous system, and non-progressive tabes dorsalis, as well as in recent nerve lesions of the late secondary period and in the cerebrospinal fluid in treated cerebrospinal cases. In fact, the celerity with which the reaction in the latter fluid responds to treatment is an index of the parasyphilitic or syphilitic nature of the case. It must be borne in mind, however, that the diagnostic value of a positive reaction is of far greater significance than a negative result, and the principle may be held applicable to the majority of biological tests.

Medical Reasoning.

THERE seems to be no constant relation between the success of a man in medicine or surgery and his power of drawing correct conclusions from given premises. This remark applies not so much to the dealings of the physician with his patients, as to his dealings with the medical world in general. We find constantly theories of therapeutic or surgical efficacy presented which would not stand the scrutiny of the most elementary logician. Many men occupying prominent positions in the medical world argue from the particular to the universal in the most blatant fashion. Because in three cases of intracranial tumour the growth could not be accurately localised, or no growth was found *post mortem*, they argue that no growth is localisable. How often, also, do we find it said that any lesion in a patient who has had syphilis is of necessity syphilitic in nature? We know of men who treat a case by three or four distinct methods simultaneously and attribute their success to one. The unpleasant fact is, we fear, that medical men are not gifted above their fellow-men with the capacity for reasoning. The necessity for an accurate and precise method of thinking is greater amongst medical men than in most other walks in life. Nothing will bring this about but a thorough education in scientific subjects. The worker in physics and chemistry can see, and others can see with him, the exact results of physical and chemical experiments. These approach absolute science; the result is not affected by the personal imagination of the beholder. In our dealings with human beings we cannot follow the whole process

of our treatment with such exactitude, and the value of our results depends too much on the attitude of mind of ourselves and of our audience. If the members of our profession were accustomed to regard things logically, if they could understand on what correct conclusions in the natural sciences depend, we should have fewer vain imaginings and more solid results in clinical research.

Infantilism.

The recent Hunterian lectures delivered before the Royal College of Surgeons of England by Professor Hastings Gilford, F.R.C.S., contain much that is of interest to students of heredity. General infantilism is concluded to be a variation of the process of normal development whereby this is seriously hindered at some stage prior to the appearance of puberty. If the condition be regarded as a fluctuation, the variation is of a regressive character, and it not infrequently ends in ordinary dwarfism. On the other hand, if the variation be more pronounced, development is delayed to a still greater extent, the reproductive organs especially feeling the arrest, so that this type tends automatically to its own extinction. Atelectosis, as one form of infantilism, is divided by Professor Gilford into three classes. The first, or most pronounced class, originates in fœtal life, the second in infancy, and the third during childhood. The analogy is traced between the first type of atelectotic individual and human beings who existed in the early Stone Age, a degenerate form of whom tends to find expression in contemporary man under degenerating or morbid conditions. Acromegaly, which expresses in an exaggerated form the ape-like characters of senile decay, as well as the degenerate simian forms of evolutionary man, is opposed to infantiiism, therefore, because the latter perpetuates the childish or undeveloped type. The importance of a study of these extremely abnormal types of development tends to throw some light upon the normal processes of growth.

Beating the Air.

A chronic argument is going on about the superiority of the male over the female mind. It is a good sort of argument, for it is unendable, and never forces conviction on the unwilling. It is carried on by all sorts and conditions of controversialists. Sir Almroth Wright is at one end of the scale, and begins by begging the question, and goes on to indulge in "unexpurgated" remarks on femininity in general. From this extreme we descend to those who observe the rules of logic and are content to adduce facts in support of their contentions. These facts, produced by the champions of the male mind, are either contradicted or ignored by the feminists. A favourite point of attack is that comparatively few inventions stand in the name of women. Someone has found out that out of some thirty thousand new inventions registered in England every year women are responsible for only five or six hundred, which proves nothing. Inventions are made by workers, not scientists; by familiarity with practice, not by theorising. Women are not extensively employed as mechanics or engineers, and consequently do not have so many opportunities for such work as men. In the arts, the one place where women shine is as novelists. The flood of novels that pours from the press is largely due to the activity of women. Much of their work is ephemeral, it is true, but it sells. Woman as a novelist is a success. The underlying reason for this is not very clear. But we could think of several instances that would show clearly that the superiority argument will be always fruitless. It ignores the simple truth that the difference between man and woman is one of quality rather than quantity.

PERSONAL.

Dr. John Stokes, M.D.Durh., has been appointed Honorary Physician to the Sheffield Children's Hospital.

Dr. William Scarisbrick, of the Benenden Sanatorium, Kent, has been appointed Tuberculosis Officer for Southend-on-Sea.

Dr. Charles V. Knight, M.D.Lond., M.R.C.S., L.R.C.P.Lond., has been appointed Surgeon to the Gloucestershire Royal Infirmary and Eye Institution.

Mr. Charles J. Heath, F.R.C.S., will preside at the forthcoming annual dinner of the British Oto-Laryngological Society on Wednesday, March 18th, at the Trocadero Restaurant, W., at 7.30 p.m.

Sir Thomas Barlow, Bart., K.C.V.O., M.D., F.R.S., will preside at a dinner at the Savoy Hotel on March 23rd in honour of Surgeon-General Gorgas, of the U.S. Army, Chief of the Sanitary Department at Panama.

Major E. T. F. Birrell, R.A.M.C., will read a paper before the United Services Medical Society, Royal Army Medical College, Grosvenor Road, S.W., on Thursday, March 12th, at 5 p.m., on "Some Experiences of the Balkan War."

Dr. Henry Head, F.R.S., will deliver the Schorstein Memorial Lecture in the anatomical theatre of the London Hospital Medical College on March 19th and 26th, at 4.15 p.m., on "The Clinical Aspects of Syphilis of the Nervous System."

Dr. Norman Moore, M.D., F.R.C.P., has been appointed by the Vice-Chancellor of the University of Cambridge to be Reader on Sir Robert Rede's foundation for the ensuing year. The lecture will be delivered in the ensuing Michaelmas term.

Sir Edward Schafer, F.R.S., Professor of Physiology in the University of Edinburgh, will deliver the Foundation Lecture upon the occasion of the 21st Anniversary Meeting of the University College Union Society at the College, Gower Street, on Thursday, March 19th.

Dr. W. T. Parry, of Ferndale, was the recipient the other day of a suitable presentation by the directors of the colliery of Messrs. D. Davis and Sons (Ltd.), as a token of their recognition of the excellent and loyal service he had rendered in the Ferndale district for 42 years, which constituted a record in the annals of colliery medical work.

The Fothergillian Gold Medal for 1914 has been awarded to Professor J. George Adami, M.A., M.D., LL.D., F.R.S., of Montreal, for his work on "Pathology and its Application to Practical Medicine and Surgery." Professor Adami hopes to be present to receive the medal on the occasion of the *conversazione* on Monday, May 18th.

It is proposed to confer the honorary degree of Sc.D., at a Congregation of the University of Cambridge, on June 9th, on the occasion of the opening of the new Physiological Laboratory by H.R.H. Prince Arthur of Connaught, upon Sir William Osler, F.R.S., Regius Professor of Medicine at Oxford; Sir David Ferrier, F.R.S., Emeritus Professor of Neuropathology in King's College, London; Sir E. A. Schäfer, F.R.S., Professor of Physiology at Edinburgh; Dr. E. H. Starling, F.R.S., Jodrell Professor of Physiology in University College, London.

CLINICAL LECTURE

ON

EPILEPSY AND EPILEPTICS. (*a*)

By F. G. CROOKSHANK, M.D.Lond., M.R.C.P.,

Physician (Out-patients) to the North-West London Hospital; Assistant Physician, the Belgrave Hospital for Children; formerly Assistant Medical Superintendent, the Northampton County Asylum, etc., etc

GENTLEMEN,—It is conventional in this country to commence any disquisition on Epilepsy, by observing that the disease is compatible with genius; proffering as proof the statement that Julius Cæsar, Mahomet, Joan of Arc, Swedenborg, Napoleon Buonaparte and various other persons were all epileptic.

We are thereby at once entangled in a mesh of question-begging fallacies; for, even if it be granted that all these famous personages were true geniuses, it is still doubtful whether the historical evidence is, in any one case, such as to enable us definitely to exclude hysteria, organic disease of the brain, alcoholism, heartblock, arteriosclerosis, or even uræmia, as possible causes of the alleged paroxysmal seizures.

Even if it were otherwise, we should still have to inquire whether the occurrence of a single seizure, on occasion of stress, warrants the diagnosis of epilepsy.

Bismarck, as we all know, on the evening of the day of Königgratz, "wept hysterically." Did that man of blood and iron suffer from hysteria? And if Cæsar did fall down that afternoon in blazing Rome; when thrice they offered him the kingly crown, and thrice did he refuse it; was he therefore necessarily an epileptic?

When I was a medical student a story was current (I see it still enshrined in Sir William Gowers's book on epilepsy), of a comrade of ours who, having been constipated for a week, ate heartily of pickled mackerel: drank freely of milk: went to a *post-mortem* examination; and straightway had a fit.

As was only wise, he then sought counsel of Sir William Gowers, and that great man, having examined and cross-examined the lad, said that, on the whole, it would have been more remarkable had he not had a fit.

He never did have another fit and he was not a subject of epilepsy. It is true that, on this solitary occasion, there was a loss or arrest of consciousness, attended, as epileptic fits so often are, by convulsion of a peculiar character. But idiopathic epilepsy is not present unless there is a recurrence of such seizures, and, moreover, unless the recurrent seizures occur, without the precedence, on each occasion, of such an exciting cause as is competent to provoke such seizures in ordinary persons.

Dr. Mercier would say that epilepsy, when the recurrent seizures are only a part of the whole of the correlated disorders of function from which the patient suffers, is only symptomatic, but that when, and only when, the seizures comprise the whole of the correlated disorders of function, it is a disease.

Now the student whose story I have just told suffered neither from symptomatic, nor from essential epilepsy, but from a single deflex epileptiform seizure due to provocation acting on a perhaps explosive nervous system.

Of course, we may, in the future, come to agree that in many cases of what we now call essential or idiopathic epilepsy, the patent disorder of function is really associated with disturbance of hidden functions, due perhaps to vascular variations, or, as Comby has recently suggested, to the presence in the cortex of such minimal lesions as may be the result of the most trifling forms of encephalitis—such, for example, as may underly the initial convulsions of scarlet fever, or other acute specific disorder.

There is consistency in this notion, even if the direct evidence in its support be not strong, for we know how many confirmed epileptics have had convulsions in childhood; and how frequently we meet with cases, clinically indistinguishable from those we call idiopathic save for this, that infantile hemiplegia is present, showing how in earlier life the cerebral cortex sustained injury from inflammatory or vascular disturbance.

However, granting that, in the sense of Comby's views, the number of cases of idiopathic or essential epilepsy must undergo reduction, we have to inquire into the existence of what may be called the epileptic predisposition, perhaps based on some textual, dynamic or chemical condition of the cortex that permits the easy provocation of convulsion.

Whenever there is clear history of familial epilepsy, such predisposition may be postulated, with some confidence perhaps; and there is moreover, I think, a pretty clear correlation between the liability to epilepsy and the existence of certain morphological characters, obvious to the acute observer.

Certainly, confirmed epileptics develop a characteristic facies: but a negative statement bearing on the point is that Mongolian imbeciles, round-headed, and with hypotonicity of the muscular tissues, are rarely epileptic. I know one epileptic Mongol, but then his father is epileptic, and it is the mother alone who exhibits indicia of Mongolism.

Further investigation, too, is required of this point; that, according to some observers, the children of those who, without obvious inherited tendencies to epilepsy, become epileptic as a result of alcoholism, are, not infrequently, the subjects of "idiopathic epilepsy"—a notion that is supported by Brown-Séquard's well-known experiments. If, however, it be suggested that the epileptic predisposition is latent in all these alcoholic epileptics who produce "epileptic progeny," we again become involved in a quagmire of doubt and logical confusion.

On the whole it seems not unreasonable to suppose that generally some predisposition exists when recurrent seizures of the nature of true epilepsy happen; but that the two factors—predisposing and excitant—are in the face of a given result usually of inverse importance.

By common agreement, however, the discussion of this subject is restricted by the definite exclusion, from the province of epilepsy, of certain happenings.

The seizures that, late in pregnancy, or during labour and the puerperium occur in association with

(*a*) Lecture delivered at the Polyclinic on November 13th, 1913.

albuminuria and other indications of disturbed function (of which acidosis is the most important) are to be removed from the categories of symptomatic and essential epilepsy alike. They do not recur unless the associated disorder of function recurs, and the same may be said of those convulsions that are frankly uræmic.

The fits that sometimes happen to persons who have granular kidneys, but are not uræmic, and who are—or some of them—the victims of saturnine intoxication are less certainly to be put on one side.

For, although they first occur, as a rule, in the second half of life, and the thickened arteries and the lead-line may point to the ætiological concomitants; still it may be that the fits persistently recur, even when lead has been eliminated and the blood-pressure is controlled.

So, too, with the alcoholics, for, although at first their seizures have clear relation to debauches, and may cease with moderation, it is not always so, and even abstinence may not avert the ultimate production of an epilepsy indistinguishable from one which is seemingly essential.

Therefore we have to agree that, just as the symptomatic insanity or delirium of typhoid fever may pass into definite insanity as the fever subsides, so may symptomatic epilepsy cease to be associated with other disturbances of function and may become a disease of "essential" nature.

The epileptiform seizures that obviously depend on reflex causation, such as the presence of worms or undigested food in the alimentary canal, and that are removable with the cause, clearly do not constitute true epilepsy in themselves. But it is hard to assert that, when, during dentition, fits occur and later recur, there may not sometimes be in the cortex of the Rolandic or other areas some slight but permanent damage done during the persistence of the vascular state that probably underlay the first attack. And again, although the fits of general paralysis are certainly foreign to our present field of discussion, we cannot deny that in certain cases of gross cerebral lesion fits that are at first clearly "Jacksonian"—*i.e.*, unilateral and unattended by loss of consciousness—may come with the passage of time to be indistinguishable from those of the essential disease.

Clearly cut lines of delimitation are therefore far to seek, and at most we can hope to trace some principles that may help us in understanding each case and group of cases.

And at the risk of seeming repetition it may be asked (1) whether there is an epilepsy depending on primary failure of orthogenesis, or development on right lines, and (2) whether there is a high grade of epilepsy compatible with mental sufficiency, and in which the fits are brought about, as Auerbach supposes those of migraine are produced, by fluctuations of intracranial pressure from time to time under stress? I think that the answer to both questions is in the affirmative. Sometimes the texture of the cortex is such that a minimal excitant—perhaps a normal physiological stimulus—is sufficient to produce discharge. What the dynamics of the brain of Cæsar on the Feast of Lupercal, or of that of Bismarck at Königgratz may have been, we can hardly guess, but we need not hope, as a recent defender in the House of Commons of the liberty of the subject has attempted to suggest, to find some Buonaparte or Mahomet amongst our village idiots.

The fact is that in the domain of medicine causation is infinitely complex; and ætiological factors are arrayed sometimes now in rank before us in the present; and sometimes in a file that extends back into an ancestral past. Inheritance strikes early as a rule; in later life exogenous factors are of the greater import. But throughout life there may be traced, often enough, a correlation between the occurrence of the old "critical periods" and the overt manifestation of the epileptic tendency or predisposition.

The essential feature of the epileptic seizure, or paroxysm, is not really the occurrence of convulsion, but that arrest or interruption of consciousness, common to both what we call "petit mal" and to the "grand mal." It may be so transient that, as often in petit mal, only a flicker of change or only a momentary fixation of expression occurs. But it may be so marked that control of the muscles that maintain posture is interrupted, whereupon the subject falls to the ground.

Convulsion, the most striking objective element in the paroxysm, may then be absent.

But besides the interruption of consciousness and the frequent convulsion there are commonly, at least, certain precedent and sequential disorders of function. The precedent phenomena are in part indications of the approach, or likely approach of a fit, and in part manifestations of the fit itself. Those that are sequential are really irregular incidents in the course of the reintegration in those workings of the central nervous system broken down in the fit, and are, as when hysterical, largely coloured by the patient's mental and nervous complexion.

So that, in the "typical fit," to borrow from the descriptive writers, we notice, after a period of restlessness or irritability, the recognition of "an aura" by the patient himself; then the well-known cry, like that "of a distracted peacock," the sudden fall, that marks the falling-sickness: the tonic spasm of all muscles with deviation of head and eyes: the remission of tonicity, with succession of clonic jerks and the onset of ever-deeper unconsciousness till the exhausted victim lies in coma: relaxed, stertorous and at the penultimate stage of total dissolution of the cerebral functions. Coma then slides away into restorative sleep, during which re-integration of function proceeds.

But, though less frequently than might be expected, every now and again coma passes into the absolute unconsciousness that constitutes death, though, except in the rarest instances, this happens only when paroxysms follow rapidly on each other in the terrible "status epilepticus": and, when in other cases sleep does not occur there may be various "post-epileptic" manifestations.

Although, often enough, the onset of a fit takes the patient and the spectators unaware, yet frequently the imminence of such is shown by sensations of headache, or giddiness, by irritability, or lethargy. These may persist for some time; and, in asylum life, the attendants, noticing moroseness or exacerbation of mental symptoms, will say that "So-and-so wants a fit."

These evidences that tension is becoming strained should, however, be distinguished from the aura, which is, indeed, the commencement of the fit itself, indicating that discharge has already begun. Auras are generally either sensory or psychical: it is in organic epilepsy that preliminary spasm is most often seen. The simplest and most common form of aura, in true epilepsy, takes the guise of some feeling; such as that of a "sinking at the pit of the stomach," a "swimming in the head," or a general flushing. But there may be disturbances of common sensation, unilateral, or "monoplegic"; there may be special visceral qualms: auditory or visual disturbances: olfactory or gustatory sensations, and the like.

Among the psychical auras we find described sometimes the recurrence of a persistent idea: sometimes a "feeling of unreality" or of strangeness: and sometimes the peculiar state of mind, familiar to many who are migrainous, of "having been through the same experience on other occasions."

Auras occur in petit mal, as well as in the major forms of epilepsy, and yet may be absent from both; although in petit mal it is not uncommon for the aura to so merge into the momentary, though complete interruption of consciousness, that it may, so to speak, seem to constitute almost the whole of the attack.

Indeed, in petit mal the interruption of consciousness may be so fleeting that to the onlooker nothing more may ever be obvious than that the thread of conversation has been lost for an instant, or that the flow of ideas has wavered. In major attacks, spasm may, though rarely, and then only when there is local organic lesion, actually precede loss of consciousness: but sometimes it attends it. The rule is, of course, for spasm to be sequential to the fall.

In major epilepsy the spasm that ensues loss of consciousness is, of course, at first, typically tonic; becoming vibratory, with gradually lengthening remissions that change its character into a succession of shock-like jerks between which there is complete relaxation: not unseldom ceasing with abruptness. But there are many variations. Rarely it is true, but sometimes, the tonic and clonic stages are separated: sometimes only tonic, and even less seldom, only clonic spasms are seen.

The phenomenon of the "March," so well known in Jacksonian epilepsies, is sometimes seen to precede generalised convulsions associated with a discoverable organic lesion: a fact which demonstrates again the practical impossibility of defining a strict line of demarcation.

That the tongue may be bitten and urine and fæces passed everyone knows. But the passage of urine and fæces is not simply due to relaxation of the sphincters in coma: it is a part of the motor discharge of the "fit" itself.

When spasm ceases, as has been said, in severe cases of the major type, the patient is in coma—at the very threshold of death. The threshold is not often crossed, it is true, unless the "status" supervenes, but it should be remembered that there is real danger from pulmonary œdema, in certain cases or subjects.

Since in coma almost all brain functions are suspended, during coma there is total paralysis: and the weakness that may be noticed after a severe fit is but residual paralysis, though less obvious because general, than when after unilateral fits, hemiplegic in allocation.

Generally, however, if there be adequate restorative sleep this weakness is not so very apparent.

Now, if diagnosis is to be complete, obviously the paroxysm itself must not escape recognition: it must be differentiated from simulated seizures: from certain paroxysms of different nature: from fits of uræmic, reflex or organic causation: and the distinction between hysteroid and epileptic fits must be borne clearly in mind, with the further determination, if there be definite indications of hysteria, of the relation between these manifestations and those of true epilepsy that may be actually present.

Possibly it may seem absurd to speak of the paroxysms themselves being overlooked: yet those of nocturnal epilepsy often are, and may only be "spotted" when matutinal illness with headache follows nocturnal enuresis. Even diurnal attacks may pass, if there be no spasm and no automatism or the like, without being considered evidence of real illness: and, even when the recurrence of "faints" is observed it may require persistence as well as courage before, from an investigation of the personal and family history, the diagnosis is fully established. But though petit mal is perhaps more often overlooked through unaccountable forgetfulness than from any other reason; there may be real difficulty, as in the case of some forms of labyrinthine attack, of distinguishing the exact nature of the seizure, and especially, of course, when tinnitus and deafness are conspicuous by their absence.

Simulation as a possible explanation of a fit has as a rule only to be considered when there is much spasm: and the whole of the circumstantial evidence has then to be weighed. But even the very elect may be deceived: and not a few simulators of epilepsy are genuinely epileptic at times. The finding of a piece of soap in the mouth is perhaps the clearest proof that a fit is a fake: and the dilatation of the pupils is the best testimony to its genuineness.

The epileptiform seizures associated with bradycardia, and with it constituting the Adams-Stokes syndrome are rare, but should not be mistaken for epilepsy: nor should the irregular seizures of general paralysis. But, just as petit mal is often taken for fainting, so fainting attacks, in cases of mitral disease of quite moderate severity, are sometimes thought to be epileptic. The causes of symptomatic and reflex epilepsy—alcohol, lead, and the like—must always be searched for. Tapeworm is often forgotten: though, if remembered, the examination of the blood for eosinophilia is an easy procedure.

One of the most serious points that arise in course of diagnosis is the possibility of the existence of a progressive organic lesion, or the persistence of the effects of trauma. And, at the risk of repetition, it has to be said that, with such lesion, or the effects of such trauma, there may become associated, sooner or later, fits indistinguishable from those of so-called idiopathic epilepsy.

The relation of hysteria to epilepsy is even more involved.

Let it first be remembered that there are several kinds, or orders, of hysterical paroxysm or seizure.

There is the vulgar fit of hysteria: familiar in casualty departments on Saturday nights, when, under the influence of beer, jealousy and constipation, an uncontrolled and uneducated woman indulges in an orgy of disorderly manifestations, from which she may be delivered by the use of the battery, or by a discreetly administered cold douche. Such attacks, not altogether infrequent even in other circles, have little to do with epilepsy.

But we also see those fits which Dr. Ormerod has called Hysteroid; wherein, after some emotional play, there is witnessed the gradual onset of a more or less regular convulsion or series of convulsions unattended by loss of consciousness; and in which the movements, if not deliberate, have at least the appearance of volitional inception, involving, moreover, no danger to the patient, though possibly to onlookers or interferers.

In such hysteroid attacks fixed deviation of head and eyes does not occur, the tongue is not bitten, micturition rarely, and defæcation never takes place.

Such attacks as these, though commonest in women, may yet be displayed by young men and even in their alcoholic elders at times.

Pressure over hysterogenic zones will, if the patient be a woman, cut short the phenomena, and

there are other methods known to discreet matrons of the humbler classes.

But, and herein lies the rub, such attacks, though common enough apart from epilepsy, do occur in epileptics (1) immediately after a major or minor seizure, and (2) alternately with fits of true epilepsy.

I well remember the case of an insane and epileptic lad, whose attendants were accustomed easily to discriminate between what they called his "real fits" and his "sham fits." But sometimes the one immediately followed the other.

Even in males, then, the demonstrably hysteroid nature of a fit is far from excluding the existence of true epilepsy.

Sometimes such hysteroid fits as these follow in such rapid succession that a veritable "status" is set up, and the patient is in peril from exhaustion. Persons have died of hysteria; and I once saw on a Sunday afternoon a girl who had so many hysteroid fits in succession—she was not an epileptic, as I knew—that had they not been stopped by morphia I believe her exhaustion would have proved fatal.

But in France it is usual to recognise fits of yet another sort: those which are called "la Grande Hystérie" or true hystero-epilepsy.

These attacks have been described once and for all by Charcot and Richer, and it is commonly said that they are very rare in England. I have, however, seen them several times and once in a man: whose case is narrated in the "Journal of Mental Science" for 1888, in conjunction with true epilepsy. But Charcot and Richer believed that these attacks are entirely hysterical, and in no wise connected with epilepsy proper. There is first, according to these great observers, a fall, and then a convulsive display, closely resembling true epilepsy, but still hysterical, and allowing of arrest by pressure on hysterogenic zones. This is Charcot's "epileptic stage of hystero-epilepsy." Then follows a bout during which there occur what are called "les grands mouvements"—violent and co-ordinated contraction of the muscles, resulting in the assumption of such extreme attitudes as emprosthotonos or opisthotonos—the stage of "clownism."

Next ensues a phase of theatrical attitudinising, the subject posing as if intent on displaying the emotional expression of anger, fear, religious or amorous ecstasy. Finally, the patient may appear to see visions or receive hallucinations of hearing.

Let it be observed that during this dramatic performance, after the preliminary epileptic stage the character of the successive acts is in an order of progressive complexity upwards, so that really we are witnessing explosive stages, not in dissolution, but in the *restoration* of cerebral faculties.

I am inclined, therefore, to class these displays with automatism and other post-epileptic and post-hysterical manifestations, as having the same relation to the earlier "epileptic stages" as has post-anæsthetic delirium to that of induction.

And, just as Ormerod's hysteroid fits may succeed either true epilepsy or mere fits of temper, so I believe the hystero-epilepsy of Charcot may follow immediately on: (1) a true epileptic fit, or (2) on an ordinary fit of temper and "hysterics": and I think these attacks of "grande hystérie" may be seen in persons, who are truly epileptic, in sequence to a true fit; or, as abroad, in persons who are never really victims of true epilepsy either major or minor.

Time does not permit the discussion of many other manifestations met with when the normal process of reintegration is interrupted or delayed, such as automatism, somnambulism, catalepsy, autohypnosis, and so forth. But it must be remembered that it is after attacks of petit mal that automatism is most frequently seen.

You remember the case of the woman who was preparing tea, with her baby in her arms, when she had a minor seizure. Perhaps, like "Charlotte, when she saw her Werter carried by her on a shutter," she, like a well-conducted person, thought it right to go on "cutting bread and butter." But, in this case, the baby's head was cut off in mistake for the loaf. Countless other instances—some tragic, others ludicrous—might be mentioned. A patient of mine, a commissionaire, went to the bank with some money. He had a slight attack, and automatically set out for his home taking the gold with him. Fortunately he recovered himself in time to save his reputation, but the explanation cost him his situation. I cannot now more than allude to the manifold relations between certifiable mental disease and epilepsy, and I must omit all discussion of pathology, of prognosis and treatment.

Doubtless, you will therefore deem these remarks most unpractical, and in a sense you are right. But I will at least say this: That the prognosis in epilepsy is often far less gloomy than is thought.

The result depends not on the routine administration of a stock bromide mixture, but on the most intelligent and individual treatment of each case, and that again on a mastery of all available therapeutic resources and on the assiduous working out of the real diagnosis.

No real diagnosis is accomplished when a mere name is given: and there must be appreciation of all the factors involved in any particular case.

This cannot be achieved unless there is a more than perfunctory grasp of what may be called by some the unpractical details of our knowledge.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by David Walsh, M.D., Senior Physician, Western Skin Hospital, London, W. Subject: "Modern Diagnosis and Treatment of Syphilis."*

ORIGINAL PAPERS.

MALINGERING. (*a*)

By Sir JOHN COLLIE.

A malingerer has been defined as "one who feigns sickness or deliberately induces or protracts an illness, or order to avoid duty, claim money compensation, excite sympathy, or for any other reason." He must be distinguished from a valetudinarian, one who, being morbidly solicitous about his health, unconsciously simulates disease or exaggerates symptoms. Many such people, if thrown out of work by accident or illness, may be converted into chronic invalids or induced to return to work, according to the attitude taken up by the medical man in attendance. It is of the utmost importance that at the earliest possible moment a return to occupation, however light, should be recommended, as there is a very definite relation between the duration of an illness and the loss of capacity for work. Many fine specimens of the British working man have been seen, who, commencing with a sturdy independence and honest desire to return to work, have gradually become mentally and morally debased as the result of idleness which the nature of the complaint made imperative. The medical treatment which an injured man receives during the first few days after an accident determines to a

(*a*) Abstract of a lecture read at a meeting of the Medico-Chirurgical Society, Glasgow.

large extent whether he is to recover quickly or slowly. Neurotic subjects are often led unconsciously by their environment to become introspective, and the practitioner who best understands his patient's circumstances, who makes due allowance for the mental attitude of his friends, who abandons the rule of thumb method of applying plasters and giving drugs, and who, feeling that he has to treat a mental as well as a physical condition, substitutes for medication the modern methods of psycho-therapeutics, will have fewer patients suffering from traumatic neurasthenia, and, indeed, from neuropathic conditions generally.

A form of malingering which of late years was not uncommon among British troops in India was associated with the practice followed by Government of sending to the Pasteur Institute in Paris all soldiers who had run the risk of infection of hydrophobia. It was observed that the number of bites said to be caused by rabid animals which could not be found was remarkably large and was increasing, and that the percentage of cures was also remarkably high. Later on it was discovered that by means of the lower jaw taken from the skeleton of a dog and attached by springs to a piece of wood, genuine bites were being produced, without any risk of hydrophobia, and attributed to some mad dog which had escaped into the jungle. A Pasteur Institute was then established at Casuli, and the treatment, robbed of the pleasure of a long sea voyage, became rather a deterrent than otherwise.

Moral malingering is practised by many lads who, finding the discipline and work of the Army irksome, procure their discharge by deliberately stealing. Technically they commit a crime, but with no criminal intent, the object of the theft being not to obtain the goods stolen, but solely to merit punishment and through it reap a benefit.

In the increase of malingering now threatened, fictitious skin diseases are likely to play an important part. Artificially produced skin lesions appear suddenly and often at irregular intervals. They are unlike any well-known skin disease, and are frequently situated in parts most easily reached by the right hand. The lesion usually runs longitudinally, and ulcers display an unusually perfect circle. The surrounding skin is as a rule significantly healthy. Lesions have a way of appearing to order. If the doctor says he would not be surprised to see a similar ulcer on the opposite side of the body in a few days, the expectation is likely to be fulfilled. Occlusive dressings, such as plaster of Paris, sometimes cause dermatitis artefacta to appear higher and higher up the limb as the dressing is extended. An eruption should always be smelled. Litmus paper often reveals acidity. When a strong caustic is used a drop may run down and leave a pear-shaped mark, lighter in colour and less inflamed than the primary lesion. The flattened sliding epithelium of a large blister should raise suspicion, and it must be remembered that a genuine secondary dermatitis may be set up by scratching and may mask the original artificial eruption. A genuine pre-existing skin disease is sometimes wilfully aggravated and kept up by patients who profit by continued disability. On the other hand, it must not be forgotten that a particular occupation may have been followed for years without the skin suffering, and yet from lowered vitality or other cause the skin resistance may give way and a true dermatitis ensue.

For the detection of simulated unilateral blindness an ingenous test has been invented by Dr. von Haselberg, of Hamburg. It consists of particoloured letters and figures used in conjunction with red and green glasses. The letters of the test are of the same size, and, with the exception of the two lowest lines, are intended to be read at the same distance as Snellen's test types. The only difference is that part of the letters are printed in black ink and part in red. For instance, one of the two V's, of which the letter W is composed, is black and the other red. The test is based on the well-known fact that anything coloured red cannot be distinguished as red, if looked at through a red glass; thus if the letter W is printed in two equal parts, one black and one red, it will, of course, be read as V. When the dark green glass is put in front of the sound eye, the whole of each letter is read with *that* eye and will be seen as if printed in black. Assuming an eye is fraudulently stated to be without sight, if the red glass is placed in front of the sound eye and the green glass in front of the alleged blind eye, should any portion of a letter printed in red be seen it is due to vision in the so-called sightless eye. Having regard to the physiological fact that no one can tell without closing or covering one eye, with which eye he sees an object, we have data upon which an attempted fraud can be definitely exposed—but, it must be done with great caution.

One of the most difficult things in medico-legal medicine is to state with any degree of accuracy the amount of disability resulting from impairment of the hand as a whole or any of its digits separately or together. The difficulty in getting a patient to close his fist or flex his forefinger when he will not and says he cannot is very great, and this is enhanced by the invariable habit patients have when they are being examined with a view to fitness or otherwise for work of involuntarily watching every movement they are asked to make, with the result that the malingerer consciously, and the honest man unconsciously, restrains all movement. No real information can be gained unless the patient's view is entirely obscured, either by a book or newspaper held in front of the eyes, or better by blindfolding of his eyes. If this is done at the beginning of the examination and the patient is asked to hold out both hands, and upon a given signal he is asked to close both hands very firmly, surprising results will often be obtained. It is often very difficult to assert that a patient has complete power of flexion of his digits when he emphatically denies it, and upon the least pressure allows his fingers to come to the straight, but the plan of interlacing the examiner's digits with the patient's and instructing him to oppose their forcible extension is a very useful one.

Loss of substance, the result of sloughing or suppuration or ulcerated wounds, when it takes place in large muscles, such as the vastus externus or the hamstrings of the quadriceps extensor sometimes produces an unsightliness out of all proportion to the diminution of power resulting from the accident. It is not infrequent therefore to find that during the process of healing, which is necessarily slow, a man has consciously or unconsciously been directed by actual loss of tissue to exaggerate the resulting disability. It is not unnatural for a layman to associate a loss of substance with a corresponding loss of function, making no allowance for the surplus power with which nature so lavishly supplies us. This is exactly the class of case in which the judicial authorities, if unassisted by a medical referee, are apt to unduly sympathise with the plaintiff. The power of contraction of muscle can often be gauged by methods which persons ignorant of anatomy cannot recognise at their true value. For

instance, a patient will vigorously resist the straightening of a joint or flexing of an ankle, while complaining of loss of power in his hamstrings or his calf muscles.

AN ECONOMICAL METHOD OF USING RADIUM FOR THERAPEUTIC PURPOSES.

By WALTER C. STEVENSON, M.D., B.Ch., D.P.H. Dub. Univ.

Surgeon and Chief X-Ray Officer, Dr. Steevens' Hospital, Dublin; Surgeon, Orthopædic Hospital, Dublin.

When radium is employed in the treatment of a superficial skin lesion, such as a port-wine mark, the radium is only separated from the skin by the glass tube or other applicator which contains it. The tube is left in position for an hour, for example, so that the skin is subject to the action of both the soft, or non-penetrating, and the hard, or penetrating, rays. The good results obtained depend on the selective action of the rays on pathological tissues; but if the dose is too big, either on account of the concentration of the radium, or the length of time it is allowed to act, the healthy skin will be injured or destroyed as well as the nævoid tissue. If, on the other hand, malignant mediastinal glands require to be treated, the rays are screened by three mm. of lead or 1 to 2 mm. of platinum, and the radium thus screened is left on for 24 hours. The screen is necessary to cut off the soft rays, as otherwise these rays would be stopped by, and act on, the skin and subcutaneous tissues only, and would not reach the tumour, so that a dose sufficient to affect the tumour would destroy the skin. When a tumour is accessible from the surface, a common practice is to bury a tube of 50 to 150 mgm. of radium in the tumour for 24 hours, or, better, two or three tubes of 50 mgm. each, so that a "cross-fire" action is obtained. It is considered necessary to screen the buried tubes heavily with 1½ mm. of platinum or 3 mm. of lead, so as again to cut off the soft rays, which would otherwise cause sloughing in the immediate neighbourhood of the tube and result in a sinus which would heal very slowly, or might not heal at all. But in spite of heavy screening, sloughing is sometimes produced with buried radium, when too much has been used, or when it has been left in too long. Normal as well as diseased tissues are destroyed, and the results are not then so satisfactory.

It may be of interest to those who have not followed the literature of radium therapy to be reminded that radium itself is quite inactive, its therapeutic effects being due to the emanation it gives off as its atoms break down. When radium is heated, or is dissolved in water or weak acids, it is de-emanated, and takes about 21 days to recover again its full emanation and therapeutic value. The emanation itself is breaking down very rapidly, being reduced by a half in 3.8 days. It forms, among other bodies, Radium B and Radium C, which bodies are of great interest to us therapeutically, as by their disintegration they produce Gamma rays, which are practically the same thing as X-rays. It has recently been shown that X-rays can be reflected and diffracted, and that they obey the laws of light generally, so that X-rays and Gamma rays are probably light waves of very short wavelength and great penetration.

Radium at the present time is worth about £20 a milligramme, and few are fortunate enough to possess 50 mgm. It follows that treatment, of malignant growths particularly, is not possible on the lines indicated above, except at institutions where there are large quantities of radium. For the past ten years I have been using what was bought at the time as 20 mgm. of pure radium bromide. It is probably not full strength. Ten mgm. are at present in an applicator with an aluminium window, and two tubes contain 5 mgm. each. I have naturally been anxious to find out the most efficacious way of using this comparatively small quantity. It is obvious that by heavy screening, not only are a number of Gamma rays completely cut off, but also the rays that penetrate the screen must lose some of their energy. In a recent paper by Rutherford and Richardson (*Phil. Mag.*, May, 1913), they show that Radium B gives off two distinct groups of Gamma rays, one extremely soft group, which is practically all absorbed by .4 mm. of aluminium; while the second group, which is harder, is absorbed to a lesser extent (12 per cent. getting through) by 3 mm. of lead, or, comparing the density of lead and human tissues, by about 3 cm., of the latter. Further, they find that Radium B initially provides about 70 per cent. of the total ionisation due to Radium B and C. The Gamma rays from Radium C consist essentially of one type, which are not completely absorbed by 30 cm. of iron, so that they would travel through several human bodies.

The problem of the economical use of radium seems therefore to involve—(1) a method of screening which will cut off the very soft group of Gamma rays from Radium B, and will allow to pass the harder group of Gamma rays from Radium B, and therefore from Radium C also; (2) a method which will permit of the maximum amount of "cross-fire" action. A *technique* which will provide an easy means of regulating the dose is desirable, and which at the same time, with only a small quantity of radium available, will ensure its efficient use in a correspondingly small area of the tumour. The pitfalls of radium therapy are necrosis from too large a dose, and stimulation of the growth from too small a dose. The happy medium is to give a lethal dose to pathological and malignant tissues, and excite the normal tissues to react and produce a fibrous scar.

I shall briefly mention one case which I treated more or less on the lines indicated. The patient, a farmer, was rapidly sinking as the result of a cancer of the tongue with extensive glandular involvement. He was so weak that he was confined to his bed for a fortnight before he was brought to me at Steevens' Hospital. He had put off coming for some weeks. He had frequently to inhale a few drops of chloroform to relieve his choking sensation. I considered it advisable to keep everything in readiness for an emergency tracheotomy. He was unable to open his mouth, could only swallow fluids, and his speech was scarcely intelligible on account of his difficulty in articulation. His pulse was 96 to 100. A large mass filled the whole right side of his neck, and extended from his mastoid to within an inch of his clavicle. There was a smaller mass on the left side. Though the case was quite hopeless, I considered I was justified in trying to relieve his distressing symptoms by the use of radium. The 20 mgm. of radium in the applicator and two tubes, screened by .1 mm. of lead, were applied over the skin on both sides of the neck simultaneously for 72 hours, being left 12 hours in one spot, so that 18 areas of skin were exposed. At the end of three days the tumour, which was stony hard to start with, had softened, the spasms were less frequent, the patient spoke more distinctly and could open his mouth a little. As the fluctuation was so marked three days later, I incised both sides of his neck and got out of each side about an ounce of sterile serum, which, on microscopic examination, proved free from cells. Serum continued to drain away for a few days. A week later, as his condition remained stationary, I buried the radium in three places on the right side of his neck, and left it in 58 hours. More serum came away. The symptoms were further alleviated. The patient could speak and open his mouth quite well, and expressed his appreciation of the treatment. As it was not advisable to do more, the patient went home the day after the radium was removed. Three weeks later I was informed: "C. died very easily. No trouble of any sort as regards laryngeal symptoms, in fact heart failure was the immediate cause of death; and what I consider most remarkable in these terrible cases was an entire absence of fœtor, stench and disagreeable odour." There was apparently no sloughing or sepsis in this case. In fact, the drainage incision had practically healed when he left Dublin. Though a fatal result from the disease was inevitable, this patient's distressing symptoms were undoubtedly relieved, and possibly his life prolonged, by the radium treatment.

It is evident that it is essential to bury the radium to obtain the greatest efficiency in its use, as otherwise more than half the Gamma rays are lost. This can be done by the use of exploring needles containing the radium or its emanation in fine capillary tubes. The glass or lead-glass capillary tubes, or, preferably in the case of the radium salt, hypodermic, platinum or silver needles, contained inside the steel exploring needle will almost completely cut off the softer group of Gamma rays from Radium B. The needles can be placed parallel and as close to, or as far apart from one another as is desirable, in accordance with the concentration of the radio-active material employed. Several minor details suggest themselves. By using a long needle and a measured stilette, the position of the capillary tube can be altered without removing the encasing needle. Platinum needles provide the most effective screening. Gilding steel needles is necessary to prevent rusting. Plugging the end of the exploring needle with hard paraffin wax is advisable. Dipping the glass tubes in colloidin will give them a protective coat in case they crack. Placing a stiff shield of perforated zinc sheeting over the tumour will prevent the needles from being pressed in, and also permit of accurate records of their position and distance apart.

By the above *technique*, in a case of inoperable cancer of the breast, for instance, I venture to think that 50 mgm. of radium would be most profitably utilised in ten needles containing 5 mgm. each buried over an area three inches in diameter, rather than in one tube screened with 3 mm. of lead or a corresponding thickness of platinum. It would be somewhat analogous to lighting a large hall by ten 100 candle-power lights in preference to one 1,000 candle-power light, which would require shading to make it tolerable for the eyes.

The needle, I think, would also be an advantage where mucous membranes are involved. Mucous membrane is proverbially hard to deal with on account of its susceptibility to overdosage if the underlying tissues are to be effectively rayed.

As to the practicability of radium needles, with proper apparatus there is little difficulty in getting 50 millicuries of radium emanation, which is equivalent to 50 milligrammes of radium, into a capillary tube one inch long, which will fit comfortably inside an ordinary exploring needle. Professor Joly tells me that a similar tube will hold 20 to 30 mgm. of radium. He has made experiments with an analogous salt—barium bromide. He used Jena glass tubes, and an electrically-heated platinum loop to melt the salt, which then flowed up the tube by capillary attraction.

In conclusion, it may be of interest to mention that emanation can be purchased from the London Radium Institute, and I trust soon from the Radium Institute which the public press states that the Royal Dublin Society is about to start in Dublin. It seems likely, therefore, that this powerful therapeutic agent will come into more general use than has been possible up to the present.

PREPARATION OF THE MOUTH FOR SURGICAL OPERATIONS. (a)

BY H. LLOYD WILLIAMS, M.R.C.S., L.D.S.,
Dental Surgeon to the West London Hospital.

WHEN any operative measures are proposed for a limb, the first care of the surgeon is to render the skin surgically clean; he accomplishes this in a variety of ways—scrubbing with soap and water, æthereal soap, etc., and finally most surgeons to-day paint the skin with a 2 per cent. solution of tinct. iodi in alcohol. The minutest care is adopted to render the skin free from all possible infection, and when that has been satisfactorily performed, the operation may be proceeded with. It cannot be said that this established routine is applied when operations in the mouth are contemplated, yet it cannot be contended that they are less necessary, nor can it be successfully maintained that reasonable, if not complete, asepsis is unobtainable.

Failure to produce favourable conditions in the mouth is followed by the same ill effects there as elsewhere, sepsis and secondary hæmorrhage; pneumonia is a more remote but direct consequence. Nor is there sufficient justification for the want of ordinary surgical precautions in the well-recognised fact that the blood-supply of the mouth is so abundant that most unfavourable conditions are frequently overcome with success—the same may be said of many other parts of the body, concerning which elaborate toilets are deemed essential before an incision is inflicted. There is a disease now recognised as being very general, and named variously Chronic Septic Periodontitis or Periostitis, Pyorrhœa Alveolaris, and Rigg's disease. The incidence of this disease at all, and especially the undeniable fact that it is very common, should serve to shake and shatter the faith of those who rely upon the excellent blood-supply to overcome septic invasion of wounds of the mouth. Other septic diseases, of which noma is the most appalling, should add weight to the argument that the mouth demands a preparation as careful and as detailed as any other part of the body before surgical operations are attempted.

I would ask your patience while I draw your attention to the lessons which that most common operation, the extraction of teeth, may have to teach. Septic infection of the bone of the socket after extraction is still frequently seen; when these cases are discussed in law courts, as they are from time to time, the operator is accused of using dirty instruments. But dirty instruments are not the cause in one per cent. of these cases, probably not one in a thousand. The cause is found in the septic condition of the mouth at the time of the operation. In our hospital clinics we have to work under conditions that are not wholly ideal, our rooms are not large enough nor airy enough, our patients are not clean, and we have to see many of them; though the extractions performed upon individuals are usually numerous and therefore leave a considerable wound, septic infection of the wound after extraction is extremely rare.

Before operation the teeth are scaled carefully and thoroughly, the *débris* is washed out by means of of a syringe and warm sterilised water or normal saline; then the gums, and especially the folds between the gums and the teeth where the tartar (salivary calculus) has been removed, are washed out with 10 per cent. H_2O_2 on wisps of cotton wool, which are carried into all crevices and pockets. In this manner a dirty mouth can be made clean in a comparatively short time, and one operates without fear of sepsis and secondary hæmorrhage.

If one root of a tooth is left in, infection of the empty socket frequently happens; also the extraction of one septic tooth leaving a septic neighbour, is not infrequently followed by secondary hæmorrhage, which seems to me to be invariably due to sepsis; the extraction of the septic tooth cures the hæmorrhage.

Another class of surgical work which falls to the lot of the dental surgeon to a general hospital is that including injuries to the jaws; of these, fracture of the mandible forms the majority.

It is a fact that few fractures of the mandible occur in healthy jaws. The rule, so far as careful observation in my own practice shows, is that the fracture occurs in the immediate neighbourhood of a septic tooth which has infected the bone; there are exceptions, but so rare that a fracture is never put up until a careful examination of the teeth in its neighbourhood has been made.

I have elsewhere (*Trans. Odont. Soc.*, 1897) described a class of fractures of the mandible between the second and third molars. The first case treated was that of a robust young man who seemed to possess a perfect set of teeth. There was great displacement so that the posterior surface of the second molar could not be seen: this is common to all fractures in this position. All the other teeth were free from caries. The fracture was put up but

(a) Paper read at the Section of Stomatology, International Congress of Medicine, July, 1913.

the bones did not unite, finally a large cavity was discovered in the posterior aspect of the second molar—the pulp in this was septic. So regularly have similar conditions prevailed that I have made it a rule to extract the second molar directly in these cases; so far the treatment has been always correct, and the subsequent union of bone rapid and uneventful. I have practised this treatment for twenty years and reported eleven or twelve cases in the *Trans. Odont. Soc.*, the communication above referred to. In nearly all the fractured mandibles that present themselves the first duty of the surgeon is to remove septic teeth from the mandible and maxilla in the neighbourhood of the fracture. Other septic roots and teeth should be removed then or at a subsequent visit—those which render cleanliness after insertion of the splint difficult in the region of the injury must be removed at the first visit.

The fœtor which is so unpleasant a feature of these cases disappears completely in a few days, and is never to be compared with that of the mouths which have not been thus cleansed. Healing is extraordinarily rapid.

When there is doubt as to the nature of an ulcer of the tongue, whether it is tuberculous, syphilitic, or epitheliomatous, a serious complication, which renders the clearing up of doubt extremely difficult, is the septic infection of the ulcer from dental origin. The same attention to the teeth and gums will serve the surgeon in a twofold manner: it will enable him to treat the suspected ulcer without septic complication, and if operative procedure is required it will have prepared the mouth.

The following case illustrates this point. A man, æt. 65, was sent to the Dental O.P. to prepare for operation. He had a deep ragged ulcer with indurated and partly undermined margins on the right side of the tongue anteriorly, reaching from the bicuspid region almost to the middle of the tip of the tongue. There was some suspicion as to the nature of the ulcer—there was a history of syphilis and the ulcer had somewhat the appearance of a broken-down gumma.

The teeth were—in the lower jaw—incisors and bicuspids, and were surrounded by a ring of tartar, inflamed gums and, between the tartar and the swollen gums, a quantity of decaying and fermenting food. In the upper jaw the right lateral seemed to be lying in a pool of pus, the canine and second bicuspid and a molar tooth were in a similar condition to the lower teeth.

The upper and lower teeth on the right side were all extracted. At the first visit, after general cleaning and scaling, the lower teeth were extracted. There was no marked improvement at the next visit. This time the constantly discharging upper right lateral and other upper and one or two lower teeth, in order to clear the affected tongue area thoroughly, were removed. There was subsequently such a marked improvement in the tongue that the operation contemplated was postponed.

There is, apparently, a considerable difficulty about the recognition of what constitutes a septic mouth, or at least what should be regarded as a clean mouth.

The conditions to be recognised fall under three categories. All three may be present in the same mouth, but it is important to keep clear in the mind the several states which constitute a septic oral cavity from dental origin.

(1) Carious Teeth.—Decayed teeth if the caries has proceeded so far as to expose the pulp and devitalise and infect it, and through the pulp infect the periosteum and bone in the neighbourhood of the apex; or if the infection has proceeded so far as to cause an abscess—the acute abscess we need not dwell upon—with its discharging sinus or gumboil. Any cavity that is so large as to contain fermenting food is dangerous. Roots when they are the sole remnants are always septic.

2. When tartar is present upon the necks of the teeth, under the margin of the gum, filling or partially filling the interdental spaces. This condition is the most common, and in my experience is very dangerous. It is present when there is little or no caries to attract notice, the teeth often look well kept and cared for. When attention is drawn to the gums they are found to be swollen at the gingival margin, they are dark in colour, and if an instrument is used they can be drawn away from the teeth showing a trough-like shallow space which is occupied by tartar clinging to the necks of the teeth and offensive food particles. There are all degrees of severity of this condition, from the small deposit of tartar—which is always dirty in whatever small quantities it may be found—to the swollen bleeding gum sheltering an incredible quantity of the most offensive and septic stuff.

This is not pyorrhœa in the common acceptation of the term; it leads to that sad state, but it is not difficult to cleanse these mouths thoroughly and fairly quickly and keep them clean afterwards, and when the tartar is thoroughly cleansed and the teeth rendered functional—those that are not functional should be extracted—the gums will quickly subside. The question of function after deforming operations will be dealt with later.

(3) Chronic Septic Periostitis.—Pyorrhœa Alveolaris. A careful study of the gums will give one a fairly reliable eye for the condition, but only instrumental examination enables a correct diagnosis to be made. There is very little deposit of tartar to be seen—in fact, true pyorrhœa is a condition which is very commonly overlooked. A flattening of the dental papilla—that is the little nipple of gum which fills the space between two teeth—should always receive further examination. A dark venous congestion over the location of the root of a tooth is sometimes present.

A fine probe passed between the gingival margin and the root is, in the normal state, immediately stopped at the line where the gum merges into the periosteum. Passing the probe gently round a diseased tooth, suddenly it will slip along the root almost to the apex. This may be oftenest at the back of the incisors, especially the upper ones—sometimes at the sides (between the teeth), sometimes in front. The X-rays show this condition well when it shows itself in the destruction of the inter-alveolar septum, but they do not give the same assistance when the disease is worst, either on the buccal or palatal aspects of the roots.

The supreme importance of diagnosis of this condition is that extraction is the only treatment which prepares the mouth for operation. Every deep pocket into which the probe slips is an abscess which cannot be even moderatedly well cleansed unless it happens to be on the buccal surface, and each one—there may be a score or more of them—must be discharged and washed separately to ensure that moderate degree of cleanliness. A mouth where this condition prevails is not prepared for any surgical operation until it is edentulous.

The mouth should be thoroughly cleansed before operations involving the adjacent and communicating cavities are undertaken. The spread of infection from the mouth to the tonsils, pharynx, and nares is of frequent occurrence, and not at all surprising. The antrum, when diseased, whether the original cause is of dental origin or not, is so closely involved in any inflammatory affections of the maxillary teeth, that the exclusion of all possibility of infection by that route is essential before any operative measures are undertaken.

The importance of a clean mouth before undertaking gastric and intestinal operations is very obvious; the swallowing of foul foodstuffs which have stagnated in the mouth for hours or days must be most dangerous.

From another point of view a clean mouth is a great factor in favour of the surgeon. It is sufficiently established that toxins are absorbed from the mouth, with unfavourable results to health; the recuperative energy of the patient is greater when intoxication or infection from the mouth is excluded with positive certainty.

There arise, in the course of treatment after intestinal operations, symptoms which are not easily explainable; so difficult indeed to understand that the cause is put down as unknown. The operation has been a perfect success, conducted with the most

scrupulous care by a most skilful surgeon, and yet the unknown something intrudes. A study of a few cases has convinced me that there is reason for further inquiry into the possibility of mouth infection.

The following is quoted as a type of the cases to which I refer:—

The patient had been under treatment for pyorrhœa alveolaris for a long time; the disease was not severe, and the patient was most careful to clean out the pockets daily with a solution of hydrogen peroxide. So long as the patient was well there was no trouble from the mouth nor difficulty in arresting the progress of the disease. An intestinal operation became necessary; on the second day—though the wound was examined and nothing found wrong—acute peritonitis set in.

The mouth in these cases is not in a fit state for any severe operation. The vital energies are lowered, and therefore the resistance in the mouth is less; at the same time the usual toilet which formerly kept the mouth clean is of necessity neglected.

Those operations of the oral cavity or its neighbourhood which involve injury to the nerves, either motor or sensory, of the mouth, cheek, or tongue, require careful consideration from the dental point of view even where, as in operation of the Gasserian ganglion, the mouth itself is not involved.

The condition which follows operation in such cases is quite typical—the teeth in the affected area are always covered, lapped one might say, in food *débris*—decaying and fetid. The gums become extremely inflamed and the margins ulcerated. Why does intolerable tic return after a varying period after destruction of the Gasserian ganglion? The relief in some cases does not extend to two years. Is it possible that the presence of teeth constantly surrounded by irritating, decaying food *débris* causes ulceration of the gums, and that the terribly depressing effect of such a state from the toxæmia which accompanies it can have some influence?

It is absolutely clear that the only rational treatment in the class of cases under discussion is to extract every tooth in the affected area at least—for the subsequent comfort and cleanliness of the patient an entirely edentulous mouth is to be recommended. The beneficial effect upon the general health of a perfectly clean mouth under these conditions is quite extraordinary.

It is difficult to speak positively of the relation of sepsis and other sources of irritation in the mouth to new growths. When there has been an ulcer of the tongue or cheek or floor of the mouth for some time, as is usual in our hospital cases, the limitation of movement so far interferes with complete functional activity, that a condition of the teeth and gums rapidly supervenes, which one sees in its less offensive state in the mouths of youths afflicted with an exposed nerve; the teeth become covered with tartar, the gums inflamed and swollen. If the gums are pressed, a whitish, semi-fluid, offensive substance is squeezed out; this consists of fermented food *débris* and dead cells, the whole mass being so permeated with bacteria as to seem to consist of nothing else.

It would be hazardous to dogmatise and aver that the new growth is due to the irritation of the tartar and the sepsis, though many cases do lend countenance to the view that the tartar, covering teeth which have not had opponents, and which therefore have been functionless for many years (as testified by the mass, hardness and rough surface of the tartar), is the irritant which has caused the growth. Jagged teeth have been recognised as causes; good teeth which have no opponents become dangerous tenants.

It is certain that the sepsis, whether the original cause or induced by the new growth, may severely aggravate the local condition, while it lays a further tax upon the patient's energy against the toxins absorbed in the putrescent matter swallowed.

Following the conclusion come to when discussing cases which interfere with innervation of the mouth, it must be recognised that limitation of movement of the tongue, or jaws, or cheek will render functional cleansing of the mouth impossible. When that is not possible the brush can never keep the mouth clean; its utmost usefulness lies in removing small particles from the cervical margins of the teeth.

Taking, then, into consideration (*a*) the age of the patient—few people over 40 are entirely free from pyorrhœa—the majority of patients are over 50.

(*b*) That the mouth has become, during the progress of the disease, extremely foul; that pyorrhœa will have been greatly aggravated if present before or almost certainly induced.

(*c*) The extreme difficulty of successful treatment before operation.

(*d*) The disadvantage to the patient after the operation of limitation of movement, plus a disturbance of innervation perhaps, and the serious risk of secondary hæmorrhage from sepsis, one is forced to the conclusion that the edentulous mouth is the ideal both from the operator's and the patient's point of view.

Sarcomata attack the young—there is no age limit to this group.

The same principles apply in the preparation for operation, the objects being, as before, cleanliness before and after the operation and the patient's interest afterwards. All carious and diseased teeth should be removed, but with a view to subsequent restoration of function healthy teeth should be preserved where such a possibility exists, and this can certainly be frequently attained when the patients are under 40; the chances for retention of teeth decrease rapidly after thirty.

Comparative statistics of carcinoma of the rectum and of the mouth are not easy to obtain, nor are they, it seems to me, of sufficient value to draw reasonably accurate inferences. Certain operations on the rectum are so much more formidable than others, and on the other hand certain operations are so little formidable, that to take either group by itself would be very misleading, while to add the groups together would render any argument, as to a common cause of death, futile.

A comparison of the results of the operations covered by a short period in the wards of one surgeon, with the results of operations performed over a period of ten years in the same hospital, may serve to confirm the view advocated in my paper—that a properly prepared mouth gives the surgeon a considerable advantage, while it confers a better chance of survival upon the patient.

DURING TEN YEARS AT THE WEST LONDON HOSPITAL.

	Operations.	Deaths.	Per cent.
Carcinoma of the mouth ...	7	2	28.6
" " lip	13	1	7.7
" " tongue ...	54	8	14.8
" " cheek ...	5	—	—
" " jaw	10	1	10

Mr. Baldwin, the Senior Surgeon at the West London Hospital, has taken a keen interest in this subject. His patients are thoroughly prepared before the operations, and his results are sufficiently striking.

He has operated on nine cases.

He has not had a death.

He has not had a single case of secondary hæmorrhage.

The wound in every case has healed by first intention within four days of the operation.

It has before been shown that gingival and periodontal diseases are very prevalent after the age of 40: most of the patients afflicted with carcinomata are fifty and over; they have as a rule suffered from limited mobility of the tongue and cheeks for some time before seeking advice; during that time the stagnation of food about the teeth and gums has either accentuated or produced caries of the teeth and disease of the gums. When a deforming operation has been successfully carried out, the limited mobility of the soft parts and the loss of complete function of any teeth left will cause stagnation and fermentation or putrefaction of food remains to take place in the mouth, to the distress and ill-health of the sufferer.

The ideal preparation for such operative measures undoubtedly is to make the mouth edentulous, and if time permits the extractions should be completed a fortnight earlier. The empty sockets are then sufficiently well closed to prevent accumulation in them of mucus, saliva, or food to the detriment of the patient.

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

Follicular Cystic Odontoma.—Mr. D'Arcy Power operated on a woman, æt. 39, who was admitted for what was formerly called a multilocular cystic epithelioma of the lower jaw. She was married, but had no children. The only appearance of trouble was shown by her chin, which was large and rounded; the skin over it was healthy. She said that five years ago the right side of her jaw had been swollen, but the swelling disappeared without treatment after the escape of some clear blood-stained fluid. She had been healthy until six months ago, when the swelling began. Examination showed that the outline of the jaw was marked by a cystic swelling, which extended across the middle line equally on both sides. There was crepitus on the right side, and it was clear that the jaw was fractured in the situation of the right lower canine tooth. Inspection of the floor of the mouth showed a bulging of the mucous membrane along the inner aspect of the alveolar border. Puncture of the swelling over the skin with a trocar and cannula allowed the escape of four drachms of clear, blood-stained and slightly viscid fluid, which contained microscopically the *débris* of epithelial cells, some of which had undergone cystic degeneration. When the fluid was drained off it was ascertained that the jaw was expanded and had undergone extensive rarefaction. Within a few hours the cyst had refilled. The clinical observations were confirmed by the skiagraph.

Mr. Power said that the case was a good example of the rare condition which used to be known as a multilocular cystic epithelioma, but which was now more properly called a follicular cystic odontoma. The tumours were not malignant, but they were locally recurrent, because they extended much more widely in the cancellous tissue of the jaw than seemed apparent. He proposed, therefore, in this case, as the woman was young and had only recently been married, to try palliative measures, as the removal of the jaw leads to very serious deformity. He intended, therefore, to make an incision along the line of the jaw beneath the chin, scrape away the diseased tissue in its whole extent, and destroy any remains in the bone by inserting a radium tube into each extremity of the mandible. He hoped by this means to eradicate the disease, but if recurrence took place it would be necessary to remove nearly the whole jaw. Previous to doing this, however, it would be necessary to invite the aid of the dental surgeons to devise some apparatus which should prevent the cut ends of the jaw from coming together whilst new calcified tissue was being formed to fill up the gap. It would be advisable that such apparatus should be worn for some time before the operation was undertaken.

Injection of Iodine in the Treatment of Varicose Veins.—The same surgeon injected varicose veins with a 1 per cent. watery solution of iodine. The varicosity was limited to the internal saphenous, which presented a cluster of veins about the centre of the leg. The internal saphenous was exposed by a half-inch transverse incision just below the knee; it was tied with a silk ligature and clamped with a pair of pressure forceps; the vein was divided between the ligature and the forceps. The same vein was exposed by a similar incision above the inner ankle; it was ligatured, clamped and divided. The clamp was then taken off the lower end and the forceps off the upper end, and a stream of a 1 per cent. watery solution of iodine was run through the lower end of the vein until it came out clear at the opening below the knee. Both ends of the vein were then ligatured, and the small skin incisions were closed. The operation was followed by considerable reaction; the whole leg swelled and bullæ were formed. But in spite of this the patient felt no pain. He returned to his work as tram conductor a fortnight later, but three days afterwards he had to be re-admitted for an acute thrombosing inflammation of the vein which had been injected, and from this it took him six weeks to recover.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, February 20th, 1914.

The President, Mr. R. D. Purefoy, M.D., F.R.C.S.I., in the Chair.

CASES ILLUSTRATING LORENZ' TREATMENT FOR CONGENITAL DISLOCATION OF HIP.

Dr. Walter C. Stevenson exhibited two cases illustrating Lorenz' treatment for congenital dislocation of hip. The first case was one of single dislocation of the right hip which was reduced eleven months ago. The child had four plasters altogether, the last of which was only put on three weeks ago, and the limb was not free to move until about a week ago. The second case was one of double congenital dislocation in which both hips were reduced eighteen months ago, and were still in plaster. The child was allowed up each day after the first three weeks.

Mr. W. S. Haughton exhibited four cases illustrating Lorenz' treatment for congenital dislocation of hip. He described the five different stages of Lorenz' treatment. The first stage was of about a month's duration, and consisted in manipulation and massage of the joint with increasing vigour. If this preliminary treatment was neglected difficulties would present themselves at later stages. The second stage was the so-called bloodless operation for reducing the dislocation. The third was a passive stage, in which the limb was wrapped in plaster to maintain the position. The plaster was usually left on for about three months unless the child smashed it, when it had to be replaced. The fourth stage was one in which the child was encouraged to do everything to assist the mobility of the joint, but in this stage also the plaster was kept on. In the fifth stage the patient was liberated from the plaster, and it would be noted that a most disappointing limp was usually present. This limp was attributed to the plaster habit produced by the abduction of the limb while in the plaster of Paris, but it could be overcome by manipulation, massage, and instruction. The treatment usually took from twelve to fifteen months to complete, and from eighteen to twenty-four months was the ideal age to commence treatment. In children over five years the difficulties increased enormously. In the first case shown the child was five years old, and the treatment was completed two years ago, so that it was apparent that the benefit was permanent. The plaster was removed fourteen months after the treatment was instituted. The second case was that of a child aged four years when the treatment started. The operation was performed in May, 1912, having been preceded by five or six weeks' manipulation and massage. The plaster was changed as required, and the limb brought down in easy stages. The last plaster was put on twelve months after the treatment commenced. X-ray photographs were shown demonstrating the formation of the acetabulum at various stages during the treatment. The third case was one of double congenital dislocation. The child was five years old when treatment commenced. Lorenz' operation was performed in November, 1911, after which the patient had an attack of acute gastritis and measles which retarded her progress. The second plaster was put on in October, 1912, and the third in May, 1913. The fourth case was one of single dislocation. It was interesting inasmuch as the age of the patient was eight years when the treatment was started.

Mr. Wheeler said that with the object of reducing the time necessary in these cases of congenital dislocation of the hip he had recently performed an operation which consisted in transplanting a portion of bone so as to form a new brim to the acetabulum, but this case had only been treated about a fortnight ago, so that it was yet too soon to form any opinion as to the result.

Mr. Stevenson, replying, said with regard to the

time in hospital it was not necessary to keep the patient in hospital during the whole time of treatment, provided he could be kept under observation from time to time.

MR. HAUGHTON, replying, said with regard to the locomotion in these children their progression was fairly strong, but the waddle was awful to look upon. He had seen a couple of adults who suffered from congenital dislocation, but it was impossible to do anything for them.

CASE OF ECTOPIA VESICÆ AFTER OPERATION.

MR. D. KENNEDY exhibited a case of ectopia vesicæ after operation. In describing the operation he said, as far as he knew, the exact operation had not been carried out before. It consisted in opening the abdominal cavity above the rudimental bladder. Having freed the bladder, the ureters and bladder were lifted out of the cavity altogether. A long incision was then made in the rectum, and into the cavity was dropped all the bladder wall that was present. The remaining steps of the operation consisted in suturing the rectum, leaving an opening for the passage of the ureters. At the time of operation the child was less than four years old, and at this age no plastic operation could be attempted on the abdominal wall, and, as a result, the child developed a ventral hernia. There was no ascending infection, which was sometimes met with in this operation. As to the child's capacity to hold urine, at present there seemed a slight leakage from the rectum from time to time, but at intervals of from two to three hours the child passed water in considerable quantities. If he were again called upon to perform this operation the only alteration he would be inclined to make was to transplant the bladder wall in the sigmoid.

MR. C. A. BALL said he was much interested in the case, as he had shown a boy five years ago upon whom he had operated for this condition by Peter's extra-peritoneal operation. This operation had the advantage that there was no risk of infection of the peritoneum. He did not know if it could be performed on the female, but it was a quicker operation, and the result in his case was satisfactory. An interesting question arose in connection with these cases—what effect the urine had on the rectum. In his case after two years the patient was bleeding badly from the rectum and several little adenomatous growths were to be seen, and one was inclined to fear that such might subsequently become malignant.

MR. GUNN said these cases were much more difficult than they appeared. The method adopted was very interesting, but he suggested that if a rectal examination was made it would probably be found that there was no bladder left. He had experience of such a case, and it appeared to him that the bladder blood supply was cut off.

MR. KENNEDY, replying, said that the transplantation of the ureters alone seemed to have been a complete failure. With regard to Mr. Gunn's point, the bladder was left practically as it was, so that any blood supply it had originally was retained.

A CASE OF TERTIARY ULCERATION TREATED BY "606."

MR. H. MOORE exhibited a case of tertiary ulceration of the face treated by "606." The principal interest in this case was the nose, which had been grafted by Dr. Graham. As far as he knew the case was not one of tertiary syphilis. It was either congenital or caused by infection when the patient was young. The history was that the infection commenced in the throat and spread to the face. The lesion healed up wonderfully rapidly, and had not anything like the deep cicatrix usually seen after the older treatment. The patient had already five injections of salvarsan, and after the third the cicatrix had healed up sufficiently to permit the nose being affixed.

Dr. GRAHAM described the operation, and showed a model demonstrating what he had done.

MR. MELDON said he thought a good many cases were marked as lupus that were not lupus, and in many cases a Wassermann test was not tried. If the ulceration progressed more rapidly than one expected in lupus, and if it tended to get deeper it might be regarded as syphilitic. He thought, perhaps, there was a double infection in the present case—namely, tuberculous and syphilitic.

MR. BLAYNEY said this case raised the question as to whether the Wassermann test was reliable. It appeared that the lesion on the patient's face was the only evidence of syphilis, and it seemed strange that a micro-organism which usually disseminated itself throughout the body should confine itself as in this case. The case in its clinical features resembled more tuberculous lupus than syphilitic lupus. The question also arose as to whether arsenic had not an effect in these cases.

The PRESIDENT said he thought Mr. Blayney had raised important points in connection with the case. It was quite open to question how far the evidence of syphilitic taint was satisfactory. The syphilitic suspicion was formed, in his opinion, by the good effect of salvarsan. Whether congenital syphilis often affected the throat and nose in the degree seen in this patient was also open to question.

MR. MOORE, replying, said the patient got mercury and iodide of potassium, and it was now proposed to stop this and give a further injection of salvarsan. Regarding the stopping of salvarsan, this would altogether depend upon the condition of the patient. It would be given again if the ulceration went on, but he would not continue it until the Wassermann test was negative. As to whether the appearance was tuberculous or syphilitic, the throat and palate showed the ulceration to be deep, and ordinary ulceration of lupoid character was not very deep. The throat healed without treatment, and this was against it being tuberculous. There were also numerous gummata to be seen. The ulceration on the face was very extensive, and there was a great deal more infiltration of the skin than in the ordinary tuberculous case. Without any Wassermann test at all he had formed the opinion that it was a case of syphilitic lupus, and the Wassermann reaction gave a plus 4. He did not consider a tuberculous lupoid ulceration of the throat would have healed up with such rapidity with salvarsan, but the next tuberculous case he saw he would give salvarsan a trial.

EXCISION OF ELBOW.

DR. CROFTON and MR. STEVENSON exhibited a case in which the elbow had been excised for tuberculous disease. The patient shown came to Dr. Steevens' Hospital about two years ago, when he gave a history of three years' lesion in his elbow. There was also a history of tuberculous disease of the lung which had cleared up. The patient stated that some years previously he had large glands in his neck and disease about the elbow. The arm was in a bad condition and the fingers very stiff. There were many lesions on the forearm, over which the skin was very soft, and it was stated that a number of surgeons advised him that the only cure was to have the arm amputated. He was at once put on injections of tuberculin, made from dissolving the bacilli in iodoform and ethyl chloride. These were continued up to .001 gramme, when there was a very severe reaction. Particular care was taken to investigate the other micro-organisms, and a coli-form bacillus was found. Accompanying the iodoform he was given dioradin. The lesion healed up at the end of about a year, with the exception of two small sinuses, at the bottom of which could be felt some small pieces of bone. It was decided to have these removed, and Mr. Stevenson performed the operation.

MR. STEVENSON said he saw this patient before any treatment was carried out. The arm was swollen, and looked as if nothing but amputation would do any good. When Dr. Crofton had treated him for a considerable time the swelling subsided and the arm had healed. When he operated he found the bones in such a healthy condition that he determined to remove sufficient to give the patient a chance of having a free joint. It was surprising the rapidity with which the wounds healed after the operation, and the result was that there was now very fair movement in the joint.

TUBERCULOUS DISEASE OF HIP.

DR. CROFTON said this boy was under Mr. Swan's care for a year, and was discharged in a Thomas's

splint. He returned after a week with a high temperature, and was at once put on injections of benzyl chloride and iodoform. In about a fortnight the temperature was normal. He was then given dioradin and tuberculin, on which he did very well The patient was in all thirteen and a half months under treatment and fifteen months in hospital. The pelvis and femur were both affected. X-ray photographs demonstrating various stages during the treatment were shown. Dr. Crofton asked if anyone present could suggest an operation to lengthen the leg. The patient was now well for about a year, and he did not consider there was any danger of a further outbreak.

COMPOUND FRACTURE OF BONES OF BOTH FEET.

Mr. Stevenson said that in this case he was sent for to amputate both feet. The patient got his feet jammed between the flanges of the wheel of a railway carriage and the line, so that the soles were simply hanging on from the toes to the heel, the skin being pulled down on the outer side throughout the whole length. He found the dorsalis pedis artery was pulsating, and the blood supply of the toes was good. The patient was treated with saline baths, and some skin supplied by the Rotunda Hospital was grafted on to the feet about twelve hours after removal from the patient. Both feet were now quite healed up, and the patient could walk without support. The case was interesting as the internal cuneiform bone was dislocated, so that its external surface was extended out to the cuboid.

ROYAL SOCIETY OF MEDICINE.

Sections of Neurology, Ophthalmology, and Otology.

Meeting held Thursday, February 26th, 1914.

Mr. William Thorburn, F.R.C.S., in the Chair.

Mr. W. T. Holmes Spicer opened a discussion on Nystagmus.

He traced the history of our knowledge of the condition, and showed how the movements of the eyeballs varied from large and obvious excursions down to the finest of movements which could only be detected with the ophthalmoscope. Out of 200 cases, he found that in nearly 50 per cent. the movements of the eyes were in a horizontal direction; about 15 per cent. were rotary, about 12 per cent. vertical. Four per cent. had mixed movements, 2 per cent. were irregular, 2 per cent. circumductory, 1 per cent. were condivergent or disjunctive, and a few were odd and unclassified. The horizontal and vertical forms varied greatly in rapidity of movement and in range, and they were nearly always conjugate, but in a few cases they were con-divergent. The rotary cases were nearly always conjugate, but con-divergent ones had been seen.

Circumductory movements were usually conjugate; he had never seen one which was not. They were often rhythmical. Use of the eyes was essential to the existence of nystagmus. The eyes were quiet during sleep, and sometimes so in the dark. It sometimes happened that on covering one eye, oscillations commenced in both. Unilateral nystagmus was not uncommon, and the movements were usually vertical, but not always. If the nystagmus had been recently acquired, a sensation of movement of objects was produced, but this was never noticed in the congenital cases. Nystagmus did not occur in those born blind, or who became so very soon after birth. It often became more marked with fatigue; in some cases light produced it, and in some it became more apparent in the dark.

He described the well-known fact that after watching objects moving in one direction, a negative after-movement of stationary objects was seen, which made them appear to go in the opposite direction. Some persons were able to produce nystagmus at will.

The most important causative factor in producing nystagmus was a defective retinal image, due to either a corneal or a lenticular lesion, or to some abnormal nerve or retinal condition. Errors of refraction had not been proved to cause this, but corrections of high degrees of astigmatism had often led to great improvement, or even to cessation of the nystagmus. Many of these patients had large refractive errors. Albinos and those with excessive pigmentation often had nystagmus. The pigment which affected eyes in this manner was usually supposed to be that of the retinal epithelium, but this could not be recognised by the ophthalmoscope, as the choroidal pigment masked it, and this might really be the case in those which were not obviously albinotic. In some cases the nystagmus was hereditary, but its cause not definitely ascertained.

As regards occupation-nystagmus, the weight of evidence was on the side of bad fixation being the primary cause, and besides miners, compositors were often affected. In spasmus nutans, the head movements preceded the nystagmus by a few weeks and they bore no relation to each other. This condition was supposed to be due to an instability of the motor centres. Mr. Spicer also briefly mentioned myoclonic nystagmus, injury cases and those of toxic origin.

Dr. James Taylor said that nystagmus, though usually associated with visual defects, was sometimes due to labyrinthine and nerve diseases, and he gave briefly the anatomical relations between these organs. With regard to the brain, nystagmus was most likely to follow disturbance of some co-ordinating mechanism in near relationship to the mid-brain, pons and cerebellum. He discussed the mechanism of this theory. It was seen in disseminated sclerosis, Friedreich's ataxy, and syringomyelia. It was common in cerebellar disease and in unilateral lesions. In most cases of cerebellar disease nystagmus was found, as also it was in local lesions in the vicinity of Deiter's nucleus. Besides the central motor mechanism, the peripheral nervous mechanism might produce it. The muscles themselves might cause it, as in myasthenia gravis. He thought that some of the conditions he had pointed out might be taken into consideration in order to explain the presence of nystagmus associated with visual conditions.

Mr. Sydney Scott said that labyrinthine conditions undoubtedly produced nystagmus. Rhythmic nystagmus might be produced in normal people by applying excessive stimuli to the semicircular canals, such as by rapid rotation, irrigating the ear with hot or cold water, or the galvanic current. He described the anatomy and the physiology of these canals, and expressed the view that "the deviation of the head and eyes is in the same direction as the current in the endolymph, and the nystagmus is in the opposite direction." He described the effect produced by stimulating each of the three canals by rotation of the head in the different planes, and also by the galvanic current. He had met with 23 examples of the "fistel symptom," and in nearly every case he had been able to verify the existence of a labyrinthine fistula, though many cases of fistula occurred without the "fistel symptom" being produced. As regards spontaneous labyrinthine nystagmus, it resembled induced nystagmus in kind and degree, being always symmetrical and generally unilateral. The less acute forms were sometimes seen in cases of acute or chronic otitis media. Spontaneous rhythmic rotary nystagmus to one side was also met with when the opposite labyrinth had become functionless, and disappeared again when both became destroyed. If the labyrinth were stimulated in cases of total blindness, such as resulted from primary optic atrophy unaccompanied by intracranial disease, rhythmic nystagmus could be provoked by rotation or irrigation. When one labyrinth was defunct, spontaneous nystagmus could be arrested by pressure on the carotid sheath of the normal side. It was possible to measure the strength of the stimulus required to produce nystagmus, for sometimes it was easier to be obtained on one side than the other. He described the various methods.

Cases were exhibited which illustrated various forms of nystagmus.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

MEETING HELD ON FEBRUARY 25TH, 1914.

Dr. J. COUBRO POTTER in the Chair.

Dr. J. COUBRO POTTER exhibited :—

(1) A case of retro-pharyngeal abscess in a woman with secondary abscess in the axilla. Owing to the serious condition of the patient a preliminary laryngotomy was performed and the upper end of the larynx plugged. The abscess was then evacuated. Recovery uneventful. Sinus now in posterior pharyngeal wall through which a fine probe can be passed touching diseased bone at the bottom. No tubercle bacilli found in pus.

The case was discussed by Mr. C. HEATH, Mr. IBBOTSON, Dr. FREDERICK SPICER, and Mr. HAYNES LOVELL, who thought that possibly the axillary abscess was primary and not secondary, as stated by the exhibitor.

Dr. COUBRO POTTER, in reply, said he looked upon it as an acute exacerbation of a chronic condition, possibly arising from tubercular disease of body of the vertebra. The fact that no tubercle bacilli were found in the discharge did not negative tuberculosis. He would be pleased to show the case again with skiagrams at some future meeting.

(2) A case of severe tinnitus in a woman with suicidal tendencies. Opinions were desired as to treatment by operation.

Mr. CHARLES HEATH said the patient did not appear to be at all distressed by the noises. The deafness was of the middle-ear type, and often these cases got well by other means of treatment than operation. Before opening the labyrinth, the question of which had been raised, it was a dangerous operation, and he would prefer, if necessary, to try the effect of a radical mastoid operation. He had seen several such cases cured by this procedure.

Mr. IBBOTSON pointed out that the tinnitus in this case commenced before the deafness and was first noticed within two hours of having a general anæsthetic for the operation of in-growing toe-nail. No previous history of any ear-trouble. The condition is steadily becoming worse, and although there was some impairment of hearing it was not great. Tested with the continuous series tuning forks, no breaks in the scale could be detected. There is no nystagmus or vertigo or other signs of labyrinthine trouble. The blood pressure is 140. The patient has been treated with the usual drugs, catheterisation, electricity, pilocarpine injections and counter-irritation, all without benefit. The case has been twice examined by a neurologist (Dr. Campbell Thomson) who can detect no signs of an organic central nervous lesion.

Dr. WALKER WOOD said the history of the case, immediately following an operation to the foot, the curiously apathetic vacant appearance of the patient, the negative findings in the functional examination of the ear, and the patient's age, all suggested to him a mental condition. He was strongly adverse to an operation upon the ear and would be inclined to try the effect of suggestive treatment. Dr. Wood had seen two cases of hysterical deafness and tinnitus cured by hypnotism. Had Mr. Ibbotson tried the effect of lumbar puncture, as it sometimes had a wonderful effect in cases of tinnitus of obscure origin ?

Mr. G. HAYNES LOVELL agreed with Dr. Wood that the condition was functional. He would not operate, and thought the suggestion of hypnotic treatment a good one.

Dr. COUBRO POTTER said his patient had principally been under the care of his colleague, Mr. Ibbotson, who had gone very carefully into the case. He agreed with the previous speakers that the condition was most probably central and not altogether labyrinthine, and he did not think the indications at present justified the performance of a radical mastoid operation or extirpation of the cochlea to cure the tinnitus.

Mr. IBBOTSON, in reply, thanked the Fellows for their helpful consideration of his case. Personally he was inclined to believe that the tinnitus was more likely to be a symptom of mental condition, the bilateral involvement and the age of the patient, 46, supporting this view. He had considered the question of suggestive treatment and was disinclined to operate as both ears were affected.

Mr. HEATH showed two patients on whom he had performed mastoid operations in order to prevent deafness.

(1) Mr. B. First seen in July, 1912, had suffered from suppuration in his right ear for four years in spite of orthodox meatal treatment. Discharge had occasionally been blood-stained. As there had never been any pain, there was probably no obstruction to drainage; in spite of this disease persisted. The perforation was marginal at the back, and the 50-inch watch was heard at 2 inches from the affected ear and at 60 from the other, the hearing on the sound side being exceptionaly good. Considering further delay for meatal treatment futile, he performed a conservative mastoid operation at once. As he (Mr. Heath) left a few days later for America to attend the International Otological Congress, the after-treatment was chiefly carried out by Mr. Wood, who was present at the meeting. In consequence of the removal of the diseased antral walls, the discharge ceased and the perforation healed. The hearing also returned and is now as good in this ear as in the other. On both sides it is above the standard which Mr. Heath regards as average perfection, that is the 50-inch watch is heard at 60 inches on both sides.

(2) Captain S. This patient had recently suffered from pneumonia, and while still in bed pain in the right ear began and lasted for three days before rupture of the drum-head. A few hours later Mr. Heath first saw him. The history indicated that there had been Eustachian obstruction and otitis media, the latter caused increased secretion, and the former prevented its escape. Pressure in the middle-ear had therefore risen and caused pain by compression of nerves. The high antro-tympanic pressure also led to absorption of septic material, a rise of temperature, and rupture of the drum-head; perforation being in the postero-superior quadrant. The rupture of the drum-head established drainage and diminished pressure and absorption, so the fever subsided. The 50-inch watch was heard at a distance of four inches, but previous to onset of otitis this has been the patient's better ear and mainstay, the other being defective. He was, therefore, extremely anxious regarding the safety of his hearing. The infection was streptococcal. Treatment: Confinement to bed with head wrapped up and hot water bottles applied to the ear. Two days later the drum-head was thrust out by swollen mucous-membrane, and the deafness consequently increased, the watch being only heard on contact. Tympanic trouble was obviously increasing. After waiting two days more and finding no improvement, a conservative mastoid operation was performed in order to arrest the disease and prevent permanent injury to this ear, upon the recovery of which the patient's future welfare depended. Operation: An attic dam was found but not a complete one, enough to cause deafness but not obstruction of drainage. Recovery from operation rapid; restoration of hearing slow. The delay in restoration shows how rapidly serious tympanic changes may occur and the importance of operating before they became irreparable. In consequence of tardy recovery of hearing, the patient was in a state of great anxiety, Mr. Heath being also anxious lest in his zeal to avoid operation he had allowed the disease to progress beyond repair. This case was only of a few days' duration, yet the changes in the tympanum were more serious than in the case previously described in which the disease had lasted for four years. Such cases prove that duration of disease is no reliable guide to treatment; which should be regulated as the pathological changes demand. This patient's hearing is now better than it was before the illness and above the standard which experience has led Mr. Heath to regard as average perfection. The pathological report by Dr. Wingrave on material from the mastoid antrum was as follows :—"A plastic exudate coagulum, mixed with antral epithelium."

Mr. Heath then read notes on

"A MASTOID CASE IN WHICH DELAY OF OPERATION CAUSED PROLONGATION OF THE DANGER BY WEEKS AND THE AFTER-TREATMENT BY MONTHS."

Miss L. M. F., æt. 16. First seen February 16th. Five weeks previously suffered from ulcerated sore throat and pain in the right ear. Twelve days severe pain before perforation and discharge with a temperature over 101°. Perforation and tympanic drainage gave no relief to pain, which continued for about a month. As a fluctuating swelling then appeared behind the ear, the patient was sent to London. A probe could be passed through a granulation midway in the external meatus into a large cavity in the mastoid process, which was draining by this route. Posterior part of drum-head bulging, thrust out by œdematous mucous membrane, some of which projected through the perforation as a polypus. No vertigo, pain or fever; Eustachian tube obstructed. The 50-inch watch was heard at one inch in the affected ear, and at 50 in the other. Pathological report:—"Swarms of bacteria, mainly streptococcal, a few staphylococci, acid-fact squames, and pus." Pain and fever having subsided and drainage being established, postponed operation for a day in order to prepare patient. Had she come while pain and fever persisted, should not have run the risk of delay. The oval cavity in the bone was an inch and a-quarter in its vertical axis. It had been formed in the weeks since the trouble began, and was the result of pressure of pent-up antral secretion which had been unable to escape through the tympanum on account of the attic dam, which was the cause of acute mastoiditis. This dam was still present at the time of operation, but was then unimportant, as the septic secretions had found exit by another route.

Remarks: Pain, fever, discharge and deafness, though lasting for a month during which good fortune only prevented fatal complications, were not considered reasons for intervention by the surgeon in charge; it was only when a swelling appeared behind the ear that he, like so many who trust to text-books, thought a mastoid operation required. Though the most urgent symptoms had subsided (namely pain and fever accompanied by a discharge) and drainage become established, the responsible surgeon had been so misled by books that he was anxious when danger was past and not anxious when danger was present. Mr. Heath said such a case as this justified a persistent demand for a revision of the teaching concerning the symptoms which justify a mastoid operation. In consequence of the extensive destruction of bone, the cavity remaining after the operation was five times as large as it would have been had it taken place within a few hours or days of the commencement of acute disease. The after-treatment therefore would last for months, thus prolonging the patient's discomfort and the surgeon's labour.

Dr. FREDERICK SPICER pointed out the great difficulty of the general practitioner in making a decision as to the necessity or otherwise for a mastoid operation. It is difficult for an otologist at times to decide if an operation is required, and necessarily it must be much more difficult for the family doctor. He thought that the indications for operation required revising. He could not quite agree with the dictum of his friend, Mr. Heath, "that a persistently discharging ear without pain means danger to hearing and a discharging ear with pain danger to life." According to that view every discharging ear ought to be operated upon. He hoped Mr. Heath would clearly state what he considered were the indications for performing a mastoid operation.

The cases were also discussed by Dr. COUBRO POTTER and Dr. WALKER WOOD.

In reply, Mr. HEATH pointed out that the treatment must depend upon the aural surgeon's ideal. If his ambition extended to the prevention of deafness from aural suppuration, he must arrest discharge before it had done harm to the tympanic apparatus, and this frequently entailed the performance of a conservative mastoid operation within a few days or weeks of the commencement of disease, according to the urgency of symptoms and condition of hearing. If, however, the aural surgeon—as some do—held the power of hearing in little estimation, and was content with saving life, then he might allow the discharge to continue until the patient died of old age, or until dangerous symptoms appeared, and then perform a radical mastoid operation.

Dr. FREDERICK SPICER showed a case of new growth on the palate which was thought by the Fellows present to be papillomatous in nature.

LIVERPOOL MEDICAL INSTITUTION.

THIRD PATHOLOGICAL MEETING HELD JAN. 29TH, 1914.

The President, Dr. E. W. HOPE, in the Chair.

MR. LITLER-JONES showed a tumour of the parotid, a sarcoma of lower jaw, epulis of upper jaw, and a fatty tumour of the floor of the mouth.

Mr. THELWALL THOMAS and Dr. BIGLAND, an epithelioma of the hand and lip in same patient, a malignant papilloma of rectum, tumour of mesentery and a dermoid tumour.

Mr. EDGAR STEVENSON, an eye removed from a negro, showing a large corneal staphyloma.

Mr. EDGAR STEVENSON and Dr. HARCOURT, a glioma retinæ.

Dr. HOLMES and Dr. HARCOURT, tubercular iritis.

Mr. DOUGLAS-CRAWFORD, three specimens of cystic kidneys, calculi in both kidneys.

Mr. G. C. E. SIMPSON, carcinoma of thyroid, carcinoma of kidney.

Prof. ERNEST GLYNN showed pneumococcal meningitis, a colour photograph of a tubercular ulcer of arm, and gave a lantern demonstration of the microscopical appearances of uterine rhabdo-sarcoma.

Prof. BEATTIE Mr. G. P. NEWBOLT, Mr. ADAIR DIGHTON, Mr. THELWALL THOMAS, and Prof. ERNEST GLYNN took part in the discussion.

Mr. RUSHTON PARKER read a note on "Pedunculated exostosis and enchondroma," and showed various diagrams illustrating the condition. In his opinion they were due to an aberrant portion of early cartilage wandering from the epiphysis to the shaft of the bone.

Mr. G. C. E. SIMPSON showed lantern slides of a case with multiple exostosis.

Dr. LEITH MURRAY read a paper upon the

IMMUNOLOGICAL RELATIONSHIPS OF MOTHER, FŒTUS AND PLACENTA.

He summarised the evidence in favour of the truly immunological status of the pregnant condition; the work of many investigators, and also his personal results being passed in review. Particular attention was devoted to complement fixation tests and to sensitisation reactions. With regard to the latter, he saw no evidence in toxic pregnancy (eclampsia) of an anaphylactic reaction. The direction of further research was outlined, and attention paid to the importance from a practical standpoint of appreciating that the problem is one of immunity production. The phase character of toxic pregnancy (hyperemesis in the first half and "eclampsism" in the second half) was commented on, and the suggestion thrown out that this might bear some relation to the demonstrated immunity phases, *i.e.*, antitoxic and lytic.

Evidence was given that the fœtus takes no part in the production of immunity, but is sensitised equally with the mother to a placental antigen.

Dr. GEMMELL discussed the paper and the importance of the study of utero-gestation in all its bearings. The laboratory work was important, but the proper teaching was a subject of great necessity.

Prof. BEATTIE, Prof. ERNEST GLYNN, Dr. MURRAY BLIGH also discussed the paper, and Dr. LEITH MURRAY replied.

FOURTH PATHOLOGICAL MEETING, HELD FEB. 26TH, 1914.

The Vice-President, Dr. W. B. WARRINGTON, in the Chair.

Mr. K. W. MONSARRAT showed an ulcer of the pylorus, which macroscopically appeared malignant, but microscopically proved to be innocent; two specimens of ulcer of the lesser curvature of the stomach, in one case caused by burns; a carcinoma of ileum, a nasal polyp of large size, and a carcinoma of the thyroid gland.

Mr. G. P. NEWBOLT, a small hard prostate, a carcinomatous cyst of the breast in a woman whose other breast had been removed thirty years previously for carcinoma; a malignant sigmoid and a mass of axillary glands removed with portions of the axillary artery and vein.

Prof. ERNEST GLYNN showed a specimen of acute fibrous pericarditis in a horse; and, with Dr. ABRAM, a liver from a man, æt. 27, showing cirrhosis.

Mr. JEANS and Dr. HOLLAND, gall stones in a case with stenosis of the pylorus and urethral calculi, 240 in number, from a pouch growing from the urethra.

Mr. G. C. E. SIMPSON showed several ureteral, prostatic, intestinal and gall stones.

Dr. BUCHANAN showed leukæmia specimens illustrating leukæmia, and demonstrated the life-history of a leucocyte.

Mr. MONSARRAT discussed the formation of prostatic stones, and gave his opinion that they were formed in the gland itself.

Dr. STANSFIELD, Dr. BUCHANAN, Dr. W. B. WARRINGTON and Prof. BEATTIE also discussed the specimens.

Prof. ERNEST GLYNN read a note on "A Case of Dysentery due to Bacillus 'Y,'" which had been isolated by Dr. Bamforth from a patient in the Royal Infirmary.

Dr. BUCHANAN gave details of the clinical picture and of the treatment.

Dr. GOWLAND gave a demonstration of the method of reconstructing embryos in wax. The special method of preparing the sections, the drawing of them by means of the "Edinger" projection apparatus, and the means by which the drawings were converted into wax plates, were explained with the aid of specimens and lantern slides. Models kindly lent by Prof. Peter Thompson and Mr. Rutherford were exhibited. Dr. Gowland pointed out the great necessity for co-operation in this branch of work, between the practising physician and surgeon on the one hand, and the pure scientist on the other hand.

Dr. W. B. WARRINGTON and Prof. ERNEST GLYNN discussed the paper, and Dr. GOWLAND replied.

THE NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD IN LIVERPOOL FEBRUARY 20TH, 1914.

The President, DR. WILLETT (Liverpool), in the Chair.

DR. GEMMELL (Liverpool) exhibited a specimen of carcinoma of cervix commencing during pregnancy, from an 8-para, æt. 34, which had caused hæmorrhage during the later months of pregnancy. Labour was normal, but the hæmorrhage continued and there was pain referred to the right hip and thigh. On examination, the cervix was enlarged, its inner surface rough and boggy. The uterus was removed by pelvic dissection, the patient making a good recovery. Microscopic section shows a glandular carcinoma.

Dr. GEMMELL also exhibited a specimen of carcinoma of ovaries, removed from a patient, æt. 41, with a diagnosis of double chronic inflammatory appendages. The growth was adherent to the floor of the pelvis, to omentum and rectum; the left contained pus. Microscopic section shows a mass of glandular carcinoma.

Dr. GEMMELL reported a case of solid ovarian tumour as a cause of dystocia necessitating Cæsarean section. The patient was a 2-para, the first confinement being normal. Twelve hours after the commencement of labour her doctor found the head obstructed by a hard swelling which filled the pelvis. This tumour could not be moved, so Cæsarean section was performed, and subsequently a solid tumour of the left ovary, the size of a fœtal head, was removed. Convalescence was complicated by a cystic swelling over the sacrum, which eventually had to be opened.

Dr. DOUGAL (Manchester) read the notes of a case of ectopic pregnancy occurring twice in the same patient. The patient, a 1-para, æt. 28, went two weeks over her period in July, 1912, and was operated upon for a ruptured ectopic pregnancy of the right tube. This tube and ovary were removed. Menstruation was now regular for 14 months, when she again went over her period for two weeks, and was now operated upon for a ruptured ectopic pregnancy of the left tube. Figures were given to illustrate the frequency of this condition.

Dr. GOWLAND (Liverpool) gave a demonstration of Born's method of reconstructing embryos in wax. The embryo was first cut in serial sections, and the method of drawing these on an enlarged scale by means of the Edinger projection apparatus was demonstrated. The conversion of the drawing on thin tissue paper into a wax plate was also shown, and the means to secure accurate orientation when the plates were superimposed to form the complete model. Great stress was laid upon the necessity of proper fixation of the embryo in as fresh a condition as possible. Models of human embryos kindly lent by Prof. Peter Thomson and Mr. N. C. Rutherford were on view. During his remarks, Dr. Gowland pointed out the necessity for a closer association between the gynæcologist and the anatomist, as only by co-operation between the two could many embryological problems be solved.

SPECIAL REPORTS.

BATH.

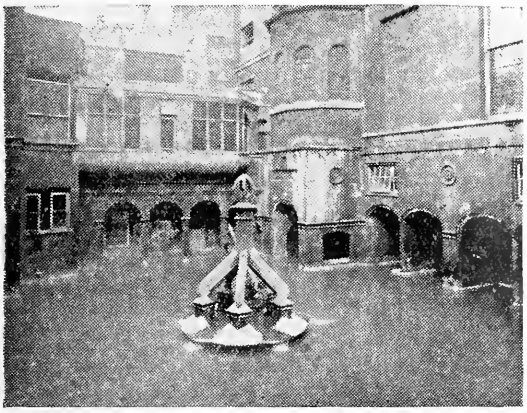
IN the medical world the hot springs of Bath have become a household word. It could hardly be otherwise, for their healing virtues have been recognised from early times. There is no need to go back to King Bladud, the legendary founder of Bath, 863 B.C. The fact that the Romans, who were past-masters in all that concerned balneology, made this city a centre of social and therapeutic importance, guarantees the soundness of its claims to recognition as a curative spa. Their beloved Aquæ Solis was splendid with temples and with baths, the remains of which are to this day carefully preserved by the Cor-

THE ROMAN BATHS.

poration of the city. The wealth of the Roman colonists is revealed at a flash by the fact that the floor of the Great Roman Bath, which occupies a hall 110 feet by 68 feet, is still covered with lead obtained from the neighbouring Mendips. Some forty tons of the metal were used for flooring the bath, a quantity that must have represented a great outlay

in those early days. Another revealing fact was the discovery of a number of exquisite intaglio gems in the conduit that brought the waters to the Great Bath. How gems worth a king's ransom got into such a place will never be known. Probably their loss is connected with some sordid theft or with some fierce incident of sack and pillage.

Interesting as the historical associations of Bath must be to persons of culture, its main interest to the medical profession must of necessity centre in its medicinal virtues. From that point of view it is intensely interesting to find the faith of the Romans in the first century is endorsed and emphasised by modern science of the twentieth century. There is no more interesting chapter in scientific progress than that attached to the discovery of radium and its allies.



The King's Spring.

One of the greatest authorities of to-day, Sir William Ramsay, F.R.S., has made an exhaustive examination of Bath waters. His report should be read by every medical man in the United Kingdom who is zealous for the reputation of the spas of his own country. Radio-activity is the key to the healing powers that the Romans found with unerring instinct in the hot springs of their beloved Aquæ Solis. An interesting picture of their magnificent temples and baths has been made on the evidence disclosed by excavation (see plate).

There is no need to discuss here the chemical and physical basis of radio-active water. The central fact of the instability of the element, radium, was shown

River Avon and Gardens.

by the discovery that it is continually parting with helium, another element. Each atom of radium shoots off an atom of helium, and changes into a gas, the so-called "radium emanation" of Rutherford and Soddy.

Lack of space forbids our following up this interesting point. For all practical purposes, however, it will be enough to remind our readers that modern science, in the person of Sir William Ramsay, has demonstrated that the King's Well is rich in radium, while the waters of the various baths contain comparatively high percentages of niton.

Medical science has driven home the conviction of the value of Bath waters in arthritic diseases by showing that the systematic drinking of radio-active water in some cases produces a striking improvement in osteo-arthritis and allied gouty and rheumatic conditions. So far as the skin is concerned it is certain that many chronic maladies are directly and indirectly benefited by a course of spa treatment at Bath.

Bath lies in a district of great natural beauty and within easy reach by train from the South of England and the Midlands. The service of baths is excellent and the Corporation has spared no trouble and expense in order to add to the attractions of their historical spa. Of late years the municipal activity has been much in evidence, and this year an honour has been done to the medical profession by the election to the mayoralty of Dr. Preston King, one of the most popular citizens of Bath.

An abundance of literature is published by the Corporation, and any medical man who may wish for detailed information as to baths, hotel accommodation, Mineral Water Hospital, or any other points will be answered fully on writing to the Waters Director, Mr. John Hutton, Pump Room, Bath.

ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD. (*a*)

Housing and town planning—these are two of the most important of the many social problems that are crying for solution to-day. Decent houses for what are somewhat cynically termed the working classes are one of the necessities of our social system. The necessity has long been unrecognised and consequently neglected. The State has lately awakened, like a giant refreshed with wine, and, by giving power and pressure to local authorities, is stimulating them to a proper sense of their responsibilities in the matter. Our present system of society is founded on the family, and a family postulates a house. It seems curious to us now that such a simple statement of undeniable fact should have been unobserved for so long. We are now waking up, and we see around us hundreds of families trying to live in houses classed as unfit for human habitation. The report before us deals with the administration of the Housing of the Working Classes Acts, 1890 to 1909, and of Part II. of the Housing, Town Planning, etc., Act, 1909, and shows that the spirit of this legislation is infusing itself more and more thoroughly through the authorities to whom its carrying out is delegated. This is encouraging. Local authorities are often slow and short-sighted, and it would not have been surprising if even the voices of the people crying in the wilderness had failed to move them. As it is, we are glad to say that the Acts in most cases are being taken full advantage of, and we hope that in a short time it will be possible to say that every family in these kingdoms has a roof over its head that keeps out the rain.

The second part of the report deals with town planning. Town planning is a new and somewhat self-conscious science. It is still rather weighed down by its comparative irrevocability. Nearly all the towns we know have sprung up as spontaneously and as purposelessly as so many toad-stool rings. They have fairly fulfilled their functions as collections of dwelling places. Still towns are far from perfect. They all show obvious inconveniences that could have been easily overcome had the town been an ordered structure rather than the conglomeration of accidents it usually is. Of course, it is a tremendous responsibility to plan a town. Use and beauty have such scope that they are in danger of overwhelming their would-be orderer. But that is no reason why the

(*a*) "Forty-Second Annual Report of the Local Government Board, 1912-13." Part II.—Housing and Town Planning. Pp. lxxii. and 67. London: H.M. Stationery Office; Darling and Son, Ltd. 1913. Price 7d.

problem should be shirked. Whatever man has not done man may do, and we therefore welcome all efforts to regulate the straggling spontaneity of our future suburbs. It is only to few that it is given to create a city such as the proposed capital for the Australian Commonwealth, but many new streets may be made less mean than their predecessors. Town planning at present means largely tinkering at old streets and designing new groups of cottages. It is a small beginning, but perhaps it is as well to start quietly.

There is great opportunity in any of our cities for making houses that are better to live in. When their conveniences are perfect and they are, in addition, good to look upon, we will feel that something has really been accomplished. In the meantime we must keep on improving our towns whenever time and money give us the chance to do so.

THE METROPOLITAN ASYLUMS BOARD. (*a*)

THIS report covers the whole sphere of operations of the Metropolitan Asylums Board for the year 1912. The activities of the Board are numerous and widespread. It works in an area of 117 square miles among a population of over four and a half million people. Its chief work, of course, is in connection with the control of the asylums and isolation hospitals of the Metropolis, and 7,271 patients in asylums and 21,378 cases of infectious disease were under its care during the year. The death-rates in hospital on the whole show a decrease on previous periods, with the exception of that for typhoid fever, which is 17.8 per cent., and consequently higher than the average of any quinquennial period since that of 1877-1881.

The Board's ambulance work includes 56,964 removals, with a mileage of 419,207 by land. On the river 301 passengers were carried and 3,405 miles covered.

The training ship *Exmouth* is under the Board's care, along with a special school for children with ringworm, two schools for those with ophthalmia, three seaside homes for children, five homes for defective children, twenty-four casual wards, and the various service departments.

The Board's expenditure is over a million pounds a year, of which asylums and hospitals account for more than half.

We have noticed in the Press that the Board are considering the advisability of applying for a coat of arms for use on buildings, etc., under its charge. We cannot but think that the monogram "M.A.B." which has become so familiar to Londoners has a significance and simplicity that no arbitrary quarterings would possess, and we should be sorry to see the good works of the Board under any other label than the one we know so well.

REPORT ON THE MILITARY INSTITUTIONS OF CANADA. (*b*)

GENERAL Sir Ian Hamilton has written a racy, readable report on the Canadian military institutions. He has personally inspected all the branches of the Canadian Militia, and has spoken to each for its own good. In the section devoted to the "Various Corps and Departments," the Medical Corps is discussed. It cannot but be gratifying to read that "in Canada, as elsewhere, the Medical Corps keeps well ahead of every other branch of the service in the completeness of its preparations for war," and that this state of affairs is "due largely to the whole-hearted support it receives from the medical profession in all its grades." Other departments of national life, such as the railways, the telegraph companies, motor and motor cyclists, etc., are advised to organise themselves for the defence of their country and to "take a leaf out of the doctors' book." The medical profession is notoriously altruistic, and probably does more unrewarded work for the world in general than any other section of the mundane activity. It is pleasing to have this spirit noted, and to remember that such time invested in the service of the nation cannot fail to bring back a recompense in the future.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Mar. 7th, 1914.

AT the Verein für Innere Medizin und Kinderheilkunde, Hr. Hamburger spoke on the

VACCINE TREATMENT OF GONORRHŒA IN CHILDREN.

He said he had subjected 21 children suffering from vulvovaginitis to vaccination treatment, using arthigon and a vaccine prepared in Sommerfeld's laboratory. The most effective, however, was a mixture of the commercial vaccines. A total of eight injections was given, one every four or five days. The initial dose was 0.05 c.cm., and this dose was gradually increased upon. The injections were intramuscular, as intravenous ones were accompanied by undesirable symptoms—rigors and collapse. In some of the children the discharge increased a good deal during the treatment, occasionally pronounced reactionary nodules appeared in the abdomen, which gave rise to a suspicion that the adnexa were sometimes affected. In the vulvovaginitis of children it could not be determined that the gonococci disappeared from the discharges. In determining the efficacy of the treatment it had to be borne in mind that the gonorrhœa of children often disappeared of itself at puberty. The speaker on the whole came to the conclusion that the vaccination treatment was not much of an aid to the local, and that alone it was quite inefficient.

Hr. Müller had treated thirteen cases by arthigon, and in seven of them the gonococci disappeared from the discharge.

Hr. Czerny had never seen any good result from vaccination treatment.

Hr. Baginsky remarked on the very infectious nature of infantile gonorrhœa. Therapeutic results were to be accepted with great reserve, as the course of the disease could not be calculated on, and spontaneous recoveries were not infrequent.

At the Gesellschaft f. Chirurgie, Hr. Ulrichs spoke on

EMBOLISM OF THE LUNGS.

He gave a report of cases of the affection that had been treated at the Urban Hospital from January 1st, 1905, to January 1st, 1909, and discussed the question of the Trendelenburg operation (removal of the embolus), and in what cases it was practicable. There were 18 cases in a total of 11,647, with 946 deaths. Of 11 post-operative cases 9 had died, 3 from incarcerated hernia, 3 after gynæcological operations, 1 perityphlitic abscess, 1 with carcinoma ventriculi, and 1 with phlegmons of the upper arm. The other cases were 7 with fractures, 4 post-partum, 1 salpingoperitonitis, 1 with varices of the lower extremities. As pointed out by Körte, the diagnosis was difficult. Three errors of diagnosis were to be reported, 1 case of periproctitic abscess and nephritis, in which, 16 days after the operation cyanosis and death took place in 20 minutes. The *post-mortem* examination showed only nephritis as the cause of death, and no embolism. A second case was one of intestinal hæmorrhage only, and the third was one of muscular degeneration of the heart. It was remarkable, and contrary to the usual, that only one of the cases was that of a male. As regarded age, the lower limit was 23, the upper being 85. Most of the fatal cases occurred between the 60th and the 75th year. As a rule the patients were not at all obese. For the occurrence of embolism the end of the first and the second week were the most dangerous periods. There was no evidence that getting up influenced the occurrence at all. In

nine cases there were no previous clinical indications; In other cases pain in the shoulder and about the heart, with acceleration of the pulse, were complained of. It was also very rare that embolism occurred in cases in which thrombosis had been previously diagnosed. Schumacher had divided embolism into three groups—the instantaneous, the rapid (within ten minutes), in which the lesser circulation was interrupted, and lastly the group in which the attack was longer than ten minutes, in which the heart was seen to be inefficient for the strain. He demanded that the operation should be begun before the commencement of the agony. As regarded pathological anatomy, the embolism affected the main trunk in two cases, the main branches in two cases, the right main branch of the pulmonary artery in two cases, and the point of bifurcation also in two. Five of the cases might be said to be favourable for operaton; two were operated on and both died. In the first case, operated on by Ruge, the embolism sat in the right pulmonary artery; in the second, operated on by Körte, and which was admitted as puerperal fever, three emboli were removed; the *post-mortem* examination showed thromboses even into the finest branches. The final decision to operate was rendered more difficult by the fact that spontaneous recoveries were not rare. His general conclusions were the following: (1) It was often not possible to distinguish between embolism and collapse; (2) a fourth of the cases died almost instantaneously; (3) the patients were mostly old and debilitated; (4) from the anatomical findings operation was possible in five cases; (5) the possibility of the Trendelenburg operation was limited; (6) the decision to operate was rendered more difficult by the fact of spontaneous recoveries taking place.

Hr. Körte related one case of error of diagnosis, that of a woman with fractured humerus. Death was sudden without cyanosis and without dyspnœa. Cardiac death was assumed, but the *post-mortem* examination showed embolism of the lungs and a weak heart. He had also seen three cases of spontaneous recovery, two with appendical peritonitis, and one with fracture of the neck of the femur.

AUSTRIA.

Vienna, Mar. 7th, 1914.

Catalysis.

At the recent Versammlung Deutscher Naturforscher und Aerzte in Vienna, Dr. E. Abel made a communication on the subject of catalysis. He there pointed out that the materials provided by observation and research in connection with the subject of catalysis had extended more in breadth and depth since the Referat held on the same subject by Wilhelm Ostwald at the Hamburg Versammlung Deutscher Naturforscher und Aerzte (1901) than during the previous half century; that is to say, than since the date of the conception of the contact or catalytic action which was established by Mitscherlich and Berzelius. If the question were asked: whether from the vast mass of individual results obtained during recent years in connection with the problems of homogeneous catalysis, a general result could be gathered? the question could, according to the view of the writer, receive an affirmative answer to the following extent: Homogeneous catalysis is wholly the result of parallel productions of non-catalytic reactions, which lead to reactionary sequelæ on the so-called catalysator, through intermediate reactionary processes. The number of intermediate-reaction catalyses that have been conclusively demonstrated, and to which belong two specimens investigated by Abel, is still, however, but very small; while on the opposite side is arrayed a disproportionately larger number of catalyses, of which the intermediate-reaction character, although it cannot be accepted with corresponding certainty, may nevertheless be regarded as of extreme probability. The grounds for discussion in this connection accordingly are the defect of certainty on the one hand, and the approximate verisimilitude on the other. The writer specially considered those groups of catalyses in which the limits of our deeper results have been reached: catalyses by hydrogen and hydroxyl ions, by undissociated acids, by neutral salts, and by solvent media; also negative catalyses. In every one of those domains the indicator presented by research pointed unmistakably in the direction of intermediate reactions. Thus, from the general results of experimental research on the subject of homogeneous catalysis, we may with great perspicuity formulate the general law: Not substances, but reactions, catalyse. By this disposition, catalytic reactions in general would be subject to inextricable periodic laws, had it not been that numerous definitely limiting laws also exist, which lead to the resulting consequence that, as a rule, but a single chemical reaction marks the definite time limit. His own researches on the iodine-iodine-ions catalysis of hydrogen peroxide furnished a thoroughly clear illustration of the reactions which formerly were known only in the minutest proportions, and through the remote obscurity of catalysator reactions and catalysator transmutations, Ostwald's law, of the necessity of equal acceleration in both of the opposite directions of the reaction, is found to be closely approximated in cases of intermediate-reaction catalyses, but not with absolute exactness.

In contradistinction to the homogeneous variety, heterogeneous catalysis is not subordinated to the influence of a single law. Here we have catalytic processes taking place, not only through the agency of intermediate reactions, but also through alterations of the degree of concentration, the greater number of the latter instances being called into play by absorption at the limiting surface of the heterogeneous catalysator, from which, according to Nernst, arises rapidity of reaction and of diffusion; while here are also found the bordering limits which furnish definite mathematical formulæ, and which are indeed often met with. Participation of the catalysator in the reaction is often very probable, but has hitherto been absolutely proved in a single instance only (Bredig).

Catalysis through colloid substances (Bredig) is substantially analogous to (macro-)heterogeneous catalysis; certain differences arising from the unusual dispersion of the colloid catalysator. These "artificial" inorganic ferments (Bredig) take rank with the "natural" ferments and enzymes. As lyophile colloids they apparently combine the reactionary powers of a molecular-(ion-)dispenser with the absorptive powers of suspended catalysators. Dr. Abel has also been recently able to demonstrate some of the typical processes which distinguish the fermentative and enzymatic effects resulting from inorganic ion catalysis, such as killing by heating, temperature optimum, ageing, limiting duration of life, etc.

Influence of Drugs on the Flow of Bile.

At the meeting of the K.k. Gesellschaft der Aerzte, Dr. F. Reach made a communication on the influence of medicaments on the flow of bile. Experiments on the lower animals demonstrated the fact that the sphincter of the ductus communis choledochus was thrown into a state of tonic contraction by the intravenous injection of morphin, of adrenalin, or of pilocarpin; while, on the contrary, that sphincter was promptly relaxed by the administration of papaverin.

Dr. J. Pál was able to corroborate that evidence of the effect of papaverin on the opening of the common bile-duct. He had seen one patient who had been the subject of icterus for ten months as a result of cholelithiasis; administration of papaverin had the effect of rapidly removing the obstruction of the biliary passages, so that the icterus completely disappeared in a short time.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH.

Royal Edinburgh Asylum.

The 101st annual report of this institution was read at the statutory meeting on February 23rd. On the last day of the year there were 796 patients in

residence; the admissions numbered 238, discharges 142, and deaths 82. The number of admissions is higher than during the past two years, but as the patients (now largely of the better class) are drawn from all parts of Scotland and England, no estimate of the amount of insanity in the immediate neighbourhood of the asylum is possible. Hereditary influences were the chief among the causes of insanity; they were present in 40 per cent. of the cases admitted. Senile decay was also prominent. The census of 1911 shows that there is a decided increase in the number of persons above 55 years of age, and the ratio of insane rises steadily with each increase in age. This, together with the recognition of senile confusion and deterioration as certifiable insanity, accounts for the apparent rise in this class of case. The commonest cause was again alcohol, which is believed to have excited an attack in 12.5 per cent. of the males and 11.5 of the females. The percentage of men is lower, and of women higher than in the last six years. In addition, alcohol was a contributory cause in another 12 per cent. of the males. It is a deplorable fact that about one fourth of the men, all of whom were liable to insanity, took alcohol to excess. The fourth most frequent cause of insanity is syphilis, which in the case of men is equal to alcoholic excess, and second only to hereditary influences. At Gartlock, Glasgow, more than a fourth of the women, and more than a third of the men, give a positive Wassermann. Dr. Kate Fraser and Dr. Watson found that more than half of 200 mental defectives also suffered from it. Useful as the Mental Deficiency Act will prove, prevention is still more important, and Dr. Robertson feels convinced that before very long steps will be initiated by which syphilis will be abolished from the land. The four causes of insanity mentioned operate at different age periods. Heredity and senility operate at the beginning and end of adult life; alcohol and syphilis in the middle period. Half of the insanity which occurs in men between the ages of 35 and 55 is therefore largely preventable.

Having reviewed the statistics of the Institution, Dr. Robertson passes to the wider question, Is insanity increasing? The actual number of insane has increased during the last decade. There were 15,719 persons registered as lunatics at last census, an increase of 2,051, or 15 per cent. over 1901, whereas the general population has increased only 6.5 per cent. The relative frequency has increased in these ten years from 3,056 to 3,302. The objections to this calculation are, first, the inclusion of the population from birth to 15 years of age. This numbers well over a million and a half, but is not an insanity producing age. Owing to the fall in the birth-rate the population under 15 has fallen, and this has had the effect of raising the ratio of insanity to the whole population. Second, it is not generally realised to what extent insanity is a mere question of age, as is shown in the following table:—

Relative Frequency of Insanity per 10,000 of the Population Living at each Age Group.

Age.	Frequency.	Age.	Frequency.
0-4	0	25-34	33
5-9	1·10	35-44	57
10-14	1·5	45-54	82
15-19	4	55-64	99
20-24	15	65-74	97

The figures relating to the age when the first attack of insanity occurs also show that the liability to break down mentally tends to increase with advancing years. Hence the frequency rate in the table is not a mere question of accumulation. It is obvious that these changes in the age distribution of the population vitiate ordinary calculations based on the two census returns. There has also, owing to emigration, been a decrease in the population between 15 and 34—also years which produce little insanity, while, on the other hand, there is an actual increase in the population above 54. The general public has not grasped the fact that the diminishing marriage-rate, birth-rate, and death-rate and emigration, have a most disturbing effect on the apparent amount of insanity in the population. When the question, "Is insanity increasing?" is asked, what is wanted is to know whether the liability to insanity is greater than before. This can be answered by dividing the population into four age groups. The first group (0-14 years) is negligible. The second, early adult, group (15-34 years) comprises more than a third of the population, and shows a frequency of 2.008 per 1,000 as compared with 1.878 in 1901. Owing to the strict immigration laws in most countries it may be assumed that emigrants are sound in mind and body, and if 80,000 sane emigrants had stayed at home there would have been no increase at this period. The third, middle age, group (35-54 years) includes more than a million persons. The insane ratio has fallen from 7.06 to 6.776 per 1,000. Allowing for the increase in numbers, which is considerable, there is an estimated decrease of 303 insane persons. As it is during this period that the stresses of civilisation are mainly borne, and the penalties paid for alcoholic and other excess, the fear that the race is decadent and may succumb to the strenuous life are groundless. The fourth group consists of those over 55, and numbers more than half a million. The frequency of insanity has risen from 8.786 to 9.640 per 1,000 in this group, meaning that there are 467 more insane than at last census. This apparent increase in senile insanity is due partly to the fact that families now scatter more than formerly, and that the aged become charged on the authorities, and are found to be best cared for in asylums.

Turning again to the affairs of his own Institution, Dr. Robertson explains that it expends about £750 a year on research, and that this year a new departure has been made in the shape of paying a visiting physician, whose sole duty it is to visit the homes of families of the parochial patients sent to the asylum. For the first time a detailed inquiry is being made into the hereditary and environmental causes of the insanity of the cases admitted. An interesting event last year was the visit of 30 Russian physicians who attended the International Medical Congress. Professor Serbsky said that the system of accomodation and treatment at Craig House was the most impressive thing he had seen in this country. Professor Bagenoff was most of all impressed by the degree of culture that must exist in a country in which such things were rendered possible, for the treatment accorded to the insane was a reliable test of a country's civilisation.

ROYAL MEDICAL SOCIETY.

The Annual President's Dinner of this, the oldest medical society in the country, was held in the hall of the society on March 3rd. Dr. Alexander, Senior President, was in the chair, and had on his right Mr. Rutherford Morrison, Newcastle, as the guest of the evening. Among those present were the Moderator of the Church of Scotland, the Lord Justice General, the Presidents of the two Royal Colleges and of the Royal Faculty in Glasgow, the Deputy Director of the Medical Services, Scottish Command, and a number of members of the Senatus Academicus, and of the staffs of the various Edinburgh hospitals. After the loyal and patriotic toasts had been pledged, the Chairman gave the toast of the Guest, to which Mr. Morrison replied in a speech full of reminiscence of pre-Listerian days in the Infirmary, of his experiences as a house surgeon to Sir Patrick Heron Watson, and of his early work as a surgeon in the North of England. He then proposed the toast of the Society, to which Dr. Haslam, one of the Presidents, responded. Dr. Sidney Smith proposed the Universities and Royal Colleges, to which Professor Harvey Littlejohn, Professor Caird, and Dr. Walker replied. "The Sister Professions," proposed by Dr. J. H. Boag, was acknowledged by the Moderator of the General Assembly of the Church of Scotland, and by the Lord Justice General, Lord Strathclyde.

GLASGOW.

GLASGOW LOCK HOSPITAL.

BAILIE DR. MCCONNELL presided at the 108th annual meeting of contributors and yearly subscribers to this hospital. 240 patients were admitted during 1913, as

against 251 in 1912, and 258 in 1911. A deplorable feature was the number of young girls requiring treatment. In the course of 1913 there were admitted 17 girls of 16, 4 of 15, 2 of 13, and 1 of 11 years of age. The financial statement is satisfactory. The Chairman, in moving the adoption of the report, said he always looked upon the hospital as having two particular functions. The primary, of course, was treatment, and that, according to the report, had been very satisfactory. The second object was teaching. That, he also thought, would be borne out by everyone as having had very beneficial results. Dr. Yellowlees submitted a motion: "That the qualified contributors to the hospital assembled here do now resolve and ordain that there shall be no teaching of men medical students in their hospital." The motion was ruled incompetent. Dr. Yellowlees has resigned his position as a director.

ROYAL ALEXANDRA INFIRMARY, PAISLEY.

Ex-Provost Bell presided at the annual meeting of directors and subscribers, and, in moving the adoption of the reports, made some pungent remarks in reference to the deficit in the annual income. During the year, he said, 700 people had been treated, and out of that number only £1 1s. 3d. had been given in return, and that was by a grateful patient. The people were not asked to pay, but he was just as convinced that the infirmary should be paid, and the money ought to come out of the medical fund paid to the panel doctor. At the same time the employers' subscriptions had decreased, and he was led to believe that this was due to the Insurance Act, but he appealed to the employers to wait a bit before restricting their money. Some had suggested using part of the endowment fund to relieve the pressure, but the rules of the institution forbade that. Recently, however, the question had been engaging the attention of the directors.

BELLEFIELD SANATORIUM, LANARK.

This institution is the property of the National Association for the Prevention of Consumption and other forms of tuberculosis. In view of the tuberculosis provisions of the National Insurance Act, 1911, and the Public Health (Scotland) Act, 1897, having devolved upon local authorities the duty of providing institutional accommodation for those insured within their areas requiring sanatorium treatment, the Corporation of Glasgow have approached the council of the Association with an offer to purchase Bellefield Sanatorium at £10,000, subject to the condition that the Association will apply that sum, and the revenue of it, for behoof of persons resident in Glasgow suffering from tuberculosis, requiring assistance over and above that provided by the Corporation under their statutory powers. The council have intimated to the members of the Glasgow and District Branch of their Association their opinion that it is in the best public interest that the offer of the Corporation should be accepted. A special meeting of the members of the Association is to be held to consider the proposal.

STATE INSURANCE AND PUBLIC HEALTH.

A discussion on this subject took place at a meeting of the Royal Philosophical Society of Glasgow on 5th inst. Dr. R. M. Buchanan presided, and among others present was Dr. A. K. Chalmers, Medical Officer of Health for Glasgow. Mr. William Jones, Secretary to Glasgow Burgh Insurance Committee, opened the discussion. In the course of his remarks Mr. Jones said, in reference to sanatorium benefit under the Act, that the Chancellor of the Exchequer, in his settlement with the doctors, earmarked the sum of 6d. per head, out of the total of 1s. 3d. available, as a payment to the doctors, in respect of domiciliary treatment; but that no evidence was yet available as to the value of the services which medical practitioners were rendering for that 6d. Hastening, however, notwithstanding the absence of evidence, to the conclusion that the doctors were being overpaid, Mr. Jones suggested that this diversion of 40 per cent. of the fund available for institutional treatment was of the nature of petty larceny on the part of the Chancellor.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE NEED FOR SPECIAL COMBINED DEPARTMENTS FOR VENEREAL DISEASES IN GENERAL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter by Dr. Meachen in your issue of February 18th is most opportune. On every hand there is evidence of an increasing desire on the part of the medical profession, and also among the general public, to wage some sort of definite campaign against venereal disease. It is not sufficient that such diseases are stated to be upon the decrease in certain localities, for thousands of cases must yet remain concealed, and therefore undiscovered by medical men. What sort of treatment these poor unfortunates receive, if any, it is difficult to imagine. They cannot, at any rate, receive injections of salvarsan or mercury, while thousands of innocent and unsuspecting victims are daily exposed to the risk of infection.

One thing is clear. These proposed departments will come, and they will come quickly. It only remains for the profession to organise them, and thus to anticipate, as it were, the recommendations of the present Royal Commission. To ensure popularity and to inspire confidence in the patients, it is essential for the whole success of the scheme that such departments (1) should not be labelled in plain English, (2) should be combined with existing skin departments, and (3) should be held in the evenings. I would suggest that they be styled "Department for Skin and Special Diseases." This is non-committal, non-repellent, and sufficiently expressive of the nature of the cases to be treated therein.

I am, Sir, yours truly,

JUDEX.

London, W.
March 9th, 1914.

OBITUARY.

MR. RANDAL COUNIHAN, F.R.C.S.I., ENNIS.

IT is with great regret we record the death of Mr. Randal Counihan, of Ennis, one of the best-known practitioners of the west of Ireland, at the early age of thirty-eight. A man of splendid physique, in his youth a distinguished athlete, the news of his early death will have surprised as well as grieved those of his friends who did not know that for some weeks past he was seriously ill. Randal Counihan was the second son of Dr. John F. Counihan, of Kilrush. After taking his medical degrees in Trinity College, Dublin, he joined his father in practice. It is only a few years since he moved to Ennis, where he found a wider scope for his abilities. He speedily became possessed of a large practice, to which his character and skill entitled him. He took an intelligent interest in affairs affecting the medical profession as a whole, and in the past year he helped to organise the medical profession of the Co. Clare, whose representative he was on the Irish Medical Committee. He was also Secretary of the local Medical Committee. Randal Counihan was a capable surgeon and a skilful, careful, and honest practitioner. In his relations to his professional brethren he was by nature and by will scrupulously honest and straightforward—the best and most trusty of friends. Ireland is the poorer by the loss of a typical Irish gentleman.

DR. ALBERT CHARLES LEWIS GUNTHER, Ph.D., M.D., LL.D., F.R.S., F.L.S., F.Z.S., formerly Keeper of the Zoological Department of the British Museum, left estate of which £2,362 is net personalty.

MR. PHILIP WHITCOMBE, M.R.C.S., L.S.A., aged 97 years, of 31 Harmer Street, Gravesend, surgeon, reputed to have been the oldest medical man in the country, left estate of the value of £15,321.

REVIEWS OF BOOKS.

DISEASES OF CHILDREN. (*a*)

IT is a pleasure to read this book, written as it is by an author of mature experience as Physician to the Belfast Hospital for Children in a clear and concise manner, and although there are many other text-books on the same subject, the reader will find much for reflection in this, and many valuable hints to interest and educate him. Students at general hospitals as a rule see little of infantile disease, and when qualified start their practice with scanty knowledge of the subject.

It is much to be regretted in the education of the medical student that special attendance for, say, six months at a Children's Hospital is not made compulsory, for children's diseases comprise a very large portion of the general practitioner's work. Dr. McCaw has divided the subject into eighteen chapters, every one of which contains a vast amount of useful information. The last chapter on "General Information" is particularly good and well worthy of careful study. We can therefore with confidence recommend this book to the student and to the busy practitioner as a useful guide in children's diseases.

PRACTICAL BACTERIOLOGY. (*b*)

THE previous editions of Professor Stitt's work were patterns of compact usefulness. By more frequent use of small type and increased number of lines on a page the present volume has had a considerable amount of useful and very reliable information squeezed in without greatly increasing the size. Especially is this true of the section on parasitology. To the laboratory worker this book can be cordially commended, while the practitioner will be grateful to the author for many suggestions and explanations of the why and wherefore of the various tests. While one hesitates to criticise small points where almost all are excellent, it may be mentioned that there is no intimation that bacteriological data that would pass muster with a surface water would perhaps condemn a deep well supply, and that it is unwise to add 40 per cent. caustic soda solution to strong sulphuric acid (p. 389).

NATURAL THERAPY. (*c*)

THIS volume forms a very suggestive, as well as instructive, introduction to the labyrinthine ways of a highly important department of therapeutics which has now a vast and daily-increasing range, and has assuredly a long future of increasing conquest secured by the ways and means within present reach—if continuously and judiciously utilised. The author expressed the opinion when about to prepare the first edition—ten years ago—that the time had come when there was a distinct want for a book on "Natural Therapy" in this country. The idea must have occurred to many scientific physicians at the opening of the present century that many of the almost miraculous conquests of mind over matter which have been achieved during the previous couple of generations could be profitably garnered with the object of turning them to the best account in the complete eradication, or partial—or temporary—alleviation of the many, many physical ills to which human flesh still remains the acknowledged and liberally-endowed heir. This extremely well printed and well illustrated manual is, of course, by no means exhaustive—the production of such a work would hardly be possible for any single individual. But it is an excellent example of the preparatory guide-book which it professes to be, and is (very obviously to the skilled eye) the work of an expert in the scientific department of clinical practice which he has made his own special study.

We have ourselves long held the view—which would be vigorously denounced by many of the vigorously "practical" as an item of paradoxical theory—that as the healing art as we have it is by no means a science—very far from it, indeed!—but really a mass of conglomerated facts and (often very much coagulated) opinions, so not one of its representatives can be properly regarded as trustworthy, far less accomplished, in the discharge of the duties of his sacred calling, who is not fairly well versed in the history of his profession. And if such historical knowledge had been carefully transmitted, after due testing and sifting, from generation to generation, suffering humanity would have been saved from the results of spasmodic advertisement of perpetually recurring rediscoveries of mischievous therapeutic agents, and would have had secured for it the continuous utilisation of the most reliable remedies. For the most reliable remedies that we possess are surely among the most venerable, and accordingly one of the very best wishes that can be expressed by the philanthropist who aims at the extermination of disease is that we may in time become as outwardly pure of person as were the ancient Greeks and modern Japs. Such a consummation would soon come to balance (and afterwards anticipate) much of the effects of the mischievous nonsense of latter-day bacteriological pathology, and save a long-suffering public from the appalling experimentation with such "remedies" as tuberculin and salvarsan. Thus while cordially recommending the present volume to the attention of every earnest physician, and excusing this brief notice on the truly genuine ground that an exhaustive examination would be as impossible as pretentious, we conclude with an expression of gratitude to the author for a genuine scientific and clinical treat.

GRAY'S ANATOMY. (*a*)

THE time-honoured and ever-popular Gray's "Anatomy" is again before us in a new—the eighteenth—edition. Since its first appearance in 1857, how many generations of medical students have been indebted to it for their anatomical teaching! The competition of modern rivals seems to have but little effect upon its continuing vitality, and in this regard it must surely have established a record in medical text-books. Many improvements have been introduced into this new edition. The whole text has been thoroughly revised and, where necessary, rewritten, about two hundred new engravings have been added, while the paragraphs on surface anatomy—always a useful and popular feature of former editions—have been collected and recast into a special chapter, instead of occurring sporadically in different parts of the work. But the change which profoundly differentiates this edition from its predecessors is the introduction of the Basle nomenclature. In our belief it was a bold step on the part of the editor to have embarked upon an undertaking of this nature—a change which, however much anatomists may admit to be a necessary advancement, still lacks general adoption in this country. We cannot think that the time is ripe for English medical students to learn this new terminology, with which neither their teachers nor examiners are familiar. The innovation is one of such magnitude that this attempt to introduce it can only bring about a condition of chaos, disturbing both to teacher and taught. And this can only be the effect until the B.N.A. becomes universally accepted, and the only terminology in use for anatomical teaching. The difficulty of this matter is further proved by the fact that the editor himself edits the B.N.A. That is, he appears to be only partially in agreement with it. In the glossary printed at the end of the volume, he divides the terminology into three heads—(1) that used in the text, (2) the Basle

(*a*) "Diseases of Children." A manual for Students and Practitioners." By John McCaw, M.D., R.U.I., F.R.C.P.Edin., etc. Senior Physician, Belfast Hospital for Sick Children. Demy 8vo., pp. 524. London: Bailliere, Tindall and Cox. 1914. Price 10s. 6d. net.

(*b*) "Practical Bacteriology and Blood Work, and Animal Parasitology." By E. R. Stitt, A.B., Ph.G., M.D., Medical Inspector, U.S. Navy. Third Edition. Pp. 411 and xv., with 4 plates and 106 other illustrations. Post 8vo. London: H. K. Lewis. 1913. Price 6s. 6d. net.

(*c*) "Natural Therapy: A Manual of Physiotherapeutics and Climatology." By Thomas D. Luke, M.D., F.R.C.S.Edin., and Norman Hay Fokes, F.R.C.S.Edin., F.R.S.Edin. With 30 plates and 125 Illustrations. Bristol: John Wright and Sons, Ltd. 1913. Pp. XVI. and 316.

(*a*) "Anatomy, Descriptive and Applied." By Henry Gray, F.R.S. Eighteenth edition. Edited by Robert Howden, M.A., D.Sc.Durh., M.B., C.M.Edin. Notes on Applied Anatomy. Revised by A. J. Lea-Blake, M.A., M.B., B.Ch.Oxon., F.R.C.P.Lond., and W. Fedde Fedden, M.S.Lond., F.R.C.S.Eng. With 1,120 illustrations, of which 431 are coloured. London: Longmans, Green and Co. 1913. Pp. 1311. Price 32s. net.

terminology, and (3) the old terminology; and the remarkable feature becomes apparent that in some instances the old terminology is retained. For example, the spleen retains its name, but the splenic artery becomes the lienal artery in the text. The axis and the odontoid process are unchanged, whereas according to the B.N.A. they should be "epistropheus" and "deus" respectively. Other similar examples are to be met with in the glossary. Thus the obvious inference is that if every author of an anatomical text-book edited the B.N.A. according to his judgment and predilection, "confusion would be worse confounded" in anatomical terminology.

THE POCKET ANATOMY. (*a*)

Good wine, they say, needs no bush; and certainly a book which has reached its seventh edition stands in no need of criticism. This pocket manual, which was first published in 1879, rapidly secured for itself quite an exceptional renown, so that many large editions and reprints have been rapidly exhausted. This new edition has been thoroughly revised by Dr. Fagge, and the Basle nomenclature, so far as its terms are in general use, has been adopted. In the revision use has been made more especially of the last edition of the late Professor Cunningham's well-known text-book. The book is admirably arranged, clearly printed, and well bound. For the medical student its possession is an absolute necessity, while for the general practitioner and surgeon it serves as a rapid means of refreshing the memory. A very complete index makes reference to its pages an easy matter.

THERAPEUTICS. (*b*)

This excellent series of manuals continues to be prepared and issued with all the clarity of thought and expression, and all the exquisite luminosity of logical reasoning on the data supplied by personal observation and garnering of collected facts, which so brilliantly characterise all the higher grade scientific literature of our gifted Gallic neighbours. Even the presumably well-worn subject of appendicitis here receives a new polish from the expert hand of M. Kendirdjy. We do not appreciate so highly his account of our present knowledge of luxations of the first phalanx of the thumb, with which the name of the deservedly-famous Leeds surgeon has, ever since the publication of his original description, been continuously associated in English-speaking countries. Like so many other modern surgeons, the writer appears to regard the sesamoid bones as the source of trouble in reduction, and fails to appreciate the grip of the lateral ligaments on the wedge-shaped displaced base of the phalanx; a grip which is inevitably increased by every effort at reduction by the ordinary modes of traction. We are pleased to note that an encouraging account is given of the present status of transfusion of blood as a therapeutic procedure. The local treatment recommended for syphilis is application of tincture of iodine. *Quant au sérum anti-streptococcique il n'a pas fait ses preuves.*

It is interesting to note that there are already candidates in the field for the election to the Council of the Royal College of Surgeons of England in June next. It is certain that there will be three, and possibly there will be five, vacancies. We have heard of the following who have decided to stand:—Mr. G. A. Ballance, of St. Thomas's, who is offering himself for re-election; Mr. McAdam Eccles, of St. Bartholomew's; Mr. William Thorburn, of Manchester; Mr. W. G. Spencer, of Westminster; and Mr. H. S. Pendlebury, of St. George's. With these and perhaps other candidates in the near future the election should be an interesting one.

(*a*) "The Pocket Anatomy." Seventh Edition. Revised and Edited by C. H. Fagge, M.B., B.S.Lond., F.R.C.S. Thirty-seventh thousand. Fscp. 8vo., pp. iv. and 307. London: Baillière, Tindall and Cox. 1914. Price 3s. 6d. net.

(*b*) "Thérapeutique des Cliniques de la Faculté de Paris." Publiée sous la Direction de M. Laignel-Lavastine, Professor Agrégé à la Faculté de Médecine, Médecin des Hopitaux. II., Chirurgie générale, Ophthalmologie, Oto-Rhino-Laryngologie, Maladies des voies Urinaires, Thérapeutique, Gynécologique, Chirurgie infantile et Orthopédie, Obstétrique. Paris: Société d'Editions Scientifiques et Médicales. F. Gittler, Directeur. 1913.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Alcon, Felix (Paris).
L'Hystérie et son Traitement. By Dr. P. Sollier. Pp. 298.

Arnold, Edward, London.
A Pocket-book of Treatment. By Ralph Winnington Leftwich, M.D. Second edition, revised. Pp. 348. Price 6s.
Diseases of the Heart. By John Cowan, D.Sc., M.D., F.R.F.P.S. With Chapters on the Electro-Cardiograph by W. T. Ritchie, M.D., F.R.C.P., and the Ocular Manifestations in Arterio-Sclerosis by Arthur J. Ballantyne, M.D., F.R.F.P.S. Pp. 438. Price 15s.
The Practice of Surgery. By Russell Howard, M.S.Lond., F.R.C.S.Eng. Pp. 1227. Price 21s.
Modern Anæsthetics. By J. Frederick W. Silk, M.D.Lond. Pp. 200. Price 3s. 6d.

Baillière, Tindall and Cox (London)
Aids to Medicine. By Bernard Hudson, M.D.Cantab., M.R.C.P. Lond. Second edition. Pp. 321. Price 3s. 6d.
Mental Deficiency (Amentia). By A. F. Tredgold, L.R.C.P. Lond., M.R.C.S.Eng. Second edition, revised and enlarged. Pp. 491. Price 12s. 6d. net.

Bale, John, Sons and Danielsson, Ltd. (London).
Scrofulosis. By Prof. Dr. G. Cornet, Berlin and Ricchenhall. Translated from the Second German Edition by J. E. Bullock, M.D., Assistant Medical Officer, The Eversfield Chest Hospital, St. Leonards-on-Sea. Pp. 515. Price 15s.
The Medical Aspects of the Greek Anthology. By J. D. Rolleston, M.D. Pp. 38.

Constable and Co. (London).
The Medical Register, 1914. Pp. 1157.
The Dentists' Register, 1914. Pp. 134.

Churchill and Co. (London).
The Royal London Ophthalmic Hospital Reports. Edited by J. Herbert Parsons. Part II. January, 1914. Price 7s. 6d.

Dental Record, Office of the, Alston House, Newman Street, London, W.
Dental Diseases in Relation to Public Health. By J. Sim Wallace, D.Sc., M.D., L.D.S. Pp. 90. Price 3s.

Ewart, Seymour, and Co., Limited, 12, Burleigh Street, Strand, London, W.C.
Electro-Pathology and Therapeutics. By Arthur E. Baines, Sometime Editor of *The Electrical Engineer*, together with a Prefatory Treatise upon the Nervous system in its Relation to Neuro-Electricity by F. H. Bowman, D.Sc., F.R.S.Edin., M.I.E.E., F.I.C., F.C.S.Berl. Pp. 120. Price 5s.

Frowde, Hr. and Hodder and Stoughton (London).
London Medical Publications Diseases of the Ear, Nose, and Throat. By George Nixon Biggs, M.B., B.S.Durh., Consulting Aural Surgeon, Evelina Hospital for Sick Children. Price 10s. 6d. net.
Cunningham's Manual of Practical Anatomy. Revised and edited by Arthur Robinson, Professor of Anatomy in the University of Edinburgh. Sixth Edition. Volume First: Superior Extremity; Inferior Extremity; Abdomen. Pp. 673. Price 10s. 6d.
The Early Diagnosis of Tubercle. By Clive Riviere, M.D., F.R.C.P. Pp. 260. Price 6s.
A Handbook for the Post-mortem Room (Oxford Medical Publications). By Alexander G. Gibson, D.M.Oxon., F.R.C.P. Lond. Pp. 140. Price 3s. 6d.
Treatment of Neurasthenia. By Dr. Paul Hartenberg. Translated by Ernest Playfair, M.B., M.R.C.P. Pp. 283. Price 6s.

Hogg, John (London).
Almost Fairyland. By John Morgan Richards. Pp. 184. Price 7s. 6d.

King and Son, P.S. (London).
A German Invasion. By Henry Sewill. Pp. 52. Price 1s.

Lewis, H. K. (London).
The Road to a Healthy Old Age. Essays Lay and Medical. By Thomas Bodley Scott. Pp. 104. Price 2s. 6d.
Ionic Medication. The Principles of the Method and an Account of the Clinical Results Obtained. By H. Lewis Jones, M.D., F.R.C.P.Lond. Second edition. Pp. 155. Price 5s. net.
Health. By Mildred M. Burgess, M.D.Lond. Pp. 175. Price 1s. 6d.
Transactions of the British Proctological Society for the Year 1913. With a list of officers, etc. Edited by W. S. Handley. Pp. 30. Price 2s. 6d.

Librairie Maloine (Paris).
Formulaire de Thérapeutic Clinique. By Dr. L. Prou. Pp. 544.

Lippincott (J. B.) Company (Philadelphia and London).
International Clinics. A Quarterly. Edited by Henry W. Cattell, A.M., M.D., Philadelphia, U.S.A., with Collaboration. Volume IV. Twenty-third Series, 1913. Pp. 312.

Longmans, Green and Co. (London).
Chemistry and its Borderland. By Alfred W. Stewart, D.Sc. Pp. 314. Price 5s.

Saunders (W. B.) Company (Philadelphia and London).
An Introduction to the History of Medicine. With Medical Chronology, Bibliographic Data, and Test Questions. By Fielding H. Garrison, A.B., M.D. Pp. 763. Price 25s.
Treatise on Diseases of the Skin. For the Use of Advanced Students and Practitioners. By Henry W. Stelwagon, M.D., Ph.D. Seventh edition, thoroughly revised. Pp. 1250. Price 25s.

Societe d'Editions Scientifiques et Medicales (Paris).
Archives Urologiques de la Clinique de Necker. By F. Legueu. Tome I. Fascicule 2.

SHAW AND SONS (London).
Lunacy Practice. By W. H. Gattie. Second edition. Pp. 59. Price 2s. 6d.

WILEY AND SONS, JOHN (New York), CHAPMAN AND HALL (London).
A Laboratory Manual of Organic Chemistry for Beginners. By A. F. Holleman, Ph.D. Edited by A. J. Walker, Ph.D. Second edition. Pp. 83. Price 4s. 6d
A Text-Book of Organic Chemistry. By A. F. Holleman, Ph.D. Edited by A. J. Walker, Ph.D., assisted by O. E. Mott, Ph.D. Fourth English edition. Pp. 621. Price 10s. 6d. net.

WRIGHT, JOHN, AND SONS, LTD. (Bristol).
A Synopsis of Surgery. By Ernest W. Hey Groves, M.S., M.D., B.Sc.Lond., F.R.C.S.Eng., Surgeon to the Bristol General Hospital. Pp. 599. Price 9s. 6d.
Herbal Simples Approved for Modern Uses of Cure. By W. T. Fernie, M.D. Third edition. Pp. 596. Price 6s. 6d.

LITERARY NOTES.

AMONG new books and new editions, we note from Messrs. Baillière, Tindall and Cox, Forsyth's "Lectures on Medical Diseases for Nurses." Crown 8vo., with 20 illustrations. (Price 3s. 6d. net.) This series of lectures forms one of the most practical books that has been published for some time for the use of nurses. It is written in the right way by a well-known London physician in easy and readable English. This work should find a ready sale among the more advanced nurses, especially those who are taking private cases. Another good book by the same firm is Hudson's "Aids to Medicine," at the same price. The first edition has been extended by the addition of another 80 pages, and in its present form this little work should be of value to the student before examination, as well as to the busy general practitioner who may wish to revise his knowledge. Of course, like other books in this series, it is not intended to replace the large text-books and manuals, but to supplement them.

* * *

OTHER books by the same firm are Tredgold's "Mental Deficiency (Amentia)." During the past few years the subject of mental deficiency has evoked a large amount of attention throughout the world. To the medical profession in particular it is a subject of great importance owing to the increase of notified insanity, and in England a special Act of Parliament on Mental Deficiency has been passed within the last few months. The present edition of this work has been brought up to date and enlarged. The following books are also in hand, but sufficient details are not yet available. The titles and approximate prices are as follows:—Krause's "Aids to Physiology," price 3s. 6d. net; Mummery's "Diseases of the Rectum and Anus," price 7s. 6d. net; Pickerill's "Prevention of Dental Caries and Oral Sepsis," price 12s. 6d. net; Underwood's "Aids to Dental Anatomy and Physiology" (3rd edition), price 2s. 6d. net.

NEW PREPARATIONS.

HEXALET.

FROM the J. D. Riedel Company, 13-14, Walbrook, come samples of a new sedative antiseptic known as "Hexalet," which is hexamethylentetramine-sulphosalicylic acid. It does not irritate the kidneys, and is well tolerated by the gastro-intestinal tract. Hexalet is indicated in acute and chronic inflammations of the bladder, posterior urethritis, bacillary infections of the urinary tract, as well as in conditions where uric acid is deposited in the kidneys or bladder. It is put up in tubes of 20 and bottles of 50 tablets, each 7.5 grains, as well as in powder form. The average dose is 1 to 2 tablets 3 to 6 times daily.

NEO-BORNYVAL.

THE iso-valerianate of borneol has been used with success in certain nervous disorders, gastric neuroses, and in gynæcological conditions. From the same firm as the above comes "Neo-Bornyval," which is an improvement upon the ordinary variety, since it is combined with valeric and glycocholic acids. This modification renders the drug more palatable, and also renders it less likely to cause gastric disturbance. The therapeutic effects are otherwise those of bornyval, viz., a sedative in functional disturbances of the nervous and circulatory systems.

POLYLACTOL.

WE have received from the Bayer Co., Ltd., a supply of a new tonic and galactagogue known as "Polylactol. This excellent preparation has for its base somatose, already well known as consisting almost entirely of meat-albumoses. The other constituents are iron in organic form, maltose and galactose. Numerous clinical tests have shown the value of polylactol in restoring the flow of milk where this had ceased altogether, and in effecting an increase in the quantity and an improvement in the quality of the milk secreted. It is palatable and soluble in water or milk and may be taken in teaspoonful doses three or four times a day with meals. If possible it should be given a few weeks before confinement in cases where the general health of the patient is below par. One tin costing 2s. 9d. lasts for about a week, so that the preparation is comparatively inexpensive. A trial supply and literature will be gladly sent on application to the Bayer Co. Ltd., 19 St. Dunstan's Hill, E.C.

MEDICAL NEWS IN BRIEF.

The Medical Society of London.

THE annual dinner of the Medical Society of London was held last week at the Hotel Metropole, Sir David Ferrier, F.R.S., in the chair. Among those present were Earl Russell, Sir T. Clifford Allbutt, Sir Alfred Pearce Gould, Professor Arthur Keith, Sir Rickman J. Godlee, Sir Francis Champneys, Sir R. Havelock Charles, Professor Howard Marsh, Sir R. Douglas Powell, Mr. C. A. Ballance, Dr. Risien Russell, Dr. Mitchell Bruce, Colonel R. M. Skinner, Surgeon-Gen. A. W. May, Dr. R. A. Young, and Mr. G. E. Guest.

In proposing "Tht Medical Society" as the toast of the evening, Sir David Ferrier sketched the life of the founder of the Society, Dr. Lettsom, who had brought the Society into existence one hundred and forty-one years ago. The original membership of the Society was thirty physicians, thirty surgeons, and thirty apothecaries or general practitioners, but their numbers were now about 700. In the early days there had been a difficulty in getting a sufficient number of Fellows to read papers, and a rule had been made that every Fellow should read a paper in rotation or pay a fine of 5s. or present a book of equivalent value to the library. It was perhaps, partly for that reason that they now had their very large library of 20,000 volumes.

Mr. Warren Low, in response, emphasised the value of the Society as affording a common platform for the physician, surgeon, general practitioner, specialist, and even, he would add, for the crank. (Laughter.)

The toast of "The Kindred Societies" was proposed by Dr. de Haviland Hall, and responded to by Sir Francis Champneys and Earl Russell.

Mr. C. B. Lockwood proposed "The Guests," and Sir Rickman Godlee and the Rev. J. A. Beaumont, Mayor of Marylebone, replied. Professor Arthur Keith proposed "The President," who, in his reply, proposed "The Health of the Officers of the Society." Dr. R. A. Young (Hon. Secretary) and Mr. George Bethel (Registrar) responded.

A Medical Research Committee.

A MEDICAL Research Committee to administer the funds made available under the National Insurance Act for the purposes of research has been constituted by regulations issued last week. The first members of the new body are:—Lord Moulton of Bank (chairman); Dr. Christopher Addison, M.P.; Mr. Waldorf Astor, M.P.; Sir T. Clifford Allbutt, Regius Professor of Physic, University of Cambridge; Mr. Charles John Bond, Senior Honorary Surgeon, Leicester Infirmary; Dr. William Bulloch, Bacteriologist to the London

Hospital and Professor of Bacteriology in the University of London; Dr. Matthew Hay, Professor of Forensic Medicine and Public Health, Aberdeen University; Dr. Frederick Gowland Hopkins, Reader in Chemical Physiology in the University of Cambridge; Brevet-Colonel Sir William Boog Leishman, Professor of Pathology, Royal Army Medical College.

An Advisory Council of Research is also constituted, to consist at the outset of the following:—Lord Moulton of Bank (chairman), Miss L. B. Aldrich-Blake, M.D., Sir W. Watson Cheyne, Sir William S. Church, Dr. Sydney Coupland, Mr. David Davies, M.P., Dr. Sheridan Delépine, Sir James Kingston Fowler, Sir Rickman J. Godlee, Sir Alfred Pearce Gould, Dr. David Hepburn, Dr. E. C. Hort, Dr. Arthur Latham, Sir John McFadyean, Dr. W. Leslie Meckenzie, Dr. J. C. McVail, Dr. W. J. Maguire, Dr. S. H. C. Martin, Dr. Robert Muir, Dr. Alexander Napier, Sir George Newman, Dr. Arthur Newsholme, Dr. J. M. O'Connor, Sir William Osler, Dr. A. C. O'Sullivan, Dr. Marcus S. Paterson, Sir Robert W. Philip, Sir William H. Power, Dr. H. Meredith Richards, Dr. Lauriston E. Shaw, Dr. Albert Smith, Dr. J. Lorrain Smith, Mr. T. J. Stafford, Dr. T. H. C. Stevenson, Mr. Harold J. Stiles, Sir Stewart Stockman, Dr. W. St. Clair Symmers, Miss Jane Walker, M.D., Dr. Norman Walker, Dr. J. Smith Whitaker, Sir Arthur Whitelegge, and Dr. G. Sims Woodhead.

It is laid down that the Medical Research Committee shall from time to time prepare schemes for research, including, if they think fit, schemes for inquiries and the collection and publication of information and statistics, and shall submit such schemes to the chairman of the National Health Insurance Joint Committee for his aproval. Before approving any scheme so submitted to him, the Chairman of the Joint Committee will consult the Advisory Council for Research.

Members of the Research Committee are to hold office for three years.

The Prudential Insurance Company.

The annual valuation report of the Prudential Assurance Company has been issued for the year 1913. The accounts show a continuance of the prosperity that has been conspicuous throughout the career of this important corporation. In the Ordinary Branch the surplus shown is £2,070,984, including a sum of £335,559 brought forward from last year. Out of this surplus the directors have added £700,000 to the Investments Reserve Fund, which, after deducting the £1,050,000 written off value of securities, stands, at December 31st, 1913, at £500,000. In the Industrial Branch the substantial surplus of £1,837,621 is shown. The total surplus of the two branches is accordingly £3.908,605. As a result of this stability additional bonuses have been granted to participating and Industrial policies. The assets of the Company stand at the large total of £40,632,021. In these days of financial unrest and instability it is pleasant year after year to record the steady progress of a great organisation that testifies strongly to the spirit of thrift among the working classes.

The Royal Colleges of Ireland and the Insurance Act.

The following resolutions have been promulgated to the Fellows, Members, and Licentiates of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland:—

Resolved: "That in the opinion of the Royal Colleges of Physicians and Surgeons, Ireland, the existing arrangements for obtaining evidence of incapacity, entitling to benefit under the National Insurance (1911) Act, have given rise to serious abuses. In forming a judgment as to whether a person is 'incapabe of work' it is essential, alike in the interests of the public and of the claimant, that the fullest possible information as to the medical condition of the claimant should be before the person whose duty it is to adjudicate on the claim. This information is, as a rule, in the possession only of the claimant's medical attendant. The Colleges are of opinion that medical certificates under the Insurance Act should be accepted only if given by the claimant's medical attendant, if any, unless such medical attendant refuses to certify. If the body claimed against desires to review a certificate, the Colleges are of opinion that the medical referee should have before him the certificate originally given by the claimant's medical attendant, and should give such medical attendant sufficient notice of the time and place of examination, and an opportunity of stating the grounds on which he arrived at the opinion expressed in his certificate."

Resolved: "That the manner in which the duties of the office of 'Medical Adviser,' either to the Insurance Commissioners or approved societies, are being discharged at present in many parts of Ireland is contrary to medical ethics, and deserving of punishment by the Colleges."

Medical Man's Fatal Mistake.

An inquest was held at Liverpool last week on the body of Dr. Jerome Eugene O'Sullivan, a local practitioner. According to the evidence, Dr. O'Sullivan, who suffered from a weak heart, took what he believed to be sal volatile on Thursday night. His wife noticed, however, a smell of opium, and he said he must have taken opium by mistake.

Sir James Barr and Dr. Bailey were telephoned for and sat with him until the next day, when he died. Dr. Bailey said it was possible Dr. O'Sullivan mistook the bottles, which were close together and similar in appearance.

The jury returned a verdict of "Death from misadventure."

University of Cambridge.

At a Congregation held on March 6th the following degrees were conferred:—

M.D.—P. H. Bahr, Trinity; R. M. Courtauld, Pembroke.

M.B. and B.C.—H. W. Willcocks, Caius; E. J. Bradley, Jesus; A. C. Clifford, Emmanuel.

M.B.—J. M. Jarvie, Emmanuel.

The Royal College of Surgeons in Ireland.

The following candidates have passed the examinations as undernoted, February, 1914:—

First Dental Examination.—Mr. Ernest S. Brabazon, Mr. William N. Brass, Mr. Charles S. Hillis, Mr. John Marron, Mr. Charles S. Morewood.

Final Dental Examination.—Mr. Joseph C. Cunningham, Mr. Eugene A. Lincoln, Mr. James J. Ryan, Mr. Alan Wiley.

Conjoint Examinations in Ireland.

The following candidates have passed the Diploma in Public Health Examination of the Royal College of Physicians and the Royal College of Surgeons:—Henry Blyth, M.B.Edin., Capt. Howard Crossle, I.M.S., M.B.Dub. (with honours), Henry Lloyd, M.D.Durh.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada

Persimmon.—The term "albumen" is now confined to describe the chief constituent of the white of egg; "albumin" to this

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the **Editor** at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR **LETTERS** intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this **JOURNAL** can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

PROVINCIAL HOUSE SURGEON.—The competition for the resident Metropolitan Hospital appointments, outside the medical schools, is naturally in favour of the London medical students. The testimonials given them by their teachers have more weight as coming in many instances from personal friends of the members of the staffs of the hospitals concerned. Again, a great influence is the personal recommendation of his teachers in favour of a hard-working and deserving student. Furthermore, if the staff of a hospital is mostly composed of members of a particular medical school, the bias in favour of a student of that school is natural. Notwithstanding, however, that all such resident appointments are not "closed boroughs" in the ordinary sense of the term, they are difficult of attainment by provincial medical students.

THE PUBLIC ROLLER TOWEL.

ROLL on, thou stiff and dark old towel-roll,
A hundred hands are wiped on thee each day;
Thou leavest mystic records, like a scroll,
And finger prints of all who pass thy way.
And where be those who saidst thou should not stay?
They pass, but thou rollest thy length immense.
—From *Judge*.

OMEGA (Barnstaple).—We will make inquiries and communicate with our correspondent by private note.

A. W. S.—We agree that our correspondent has grounds for complaint; but we doubt the expediency of pursuing the matter further.

WORKMEN'S COMPENSATION ACT, 1906.

THE Home Secretary gives notice that, in consequence of the death of Dr. F. H. Hawkins, the appointment of Medical Referee under the Workmen's Compensation Act, 1906, for Reading, Newbury, Farnham and Aldershot, and Chertsey County Courts is now vacant.

Applications for the post should be addressed to the Private Secretary, Home Office, Whitehall, London, S.W., and should reach him not later than the 2nd April, 1914.

S. T.—Professor Albert Koch died on May 27th, 1910. Besides his discovery of the tubercle bacillus in 1882, he was the first to demonstrate the transmission of infectious diseases artificially from animal to animal, the results of which have proved so invaluable in the study of bacteriological science

DR. B. P. M.—A quarter per cent. solution of nitrate of silver is ample for all purposes.

A CONFERENCE ON SUMMER DIARRHŒA.

THE Earl of Shaftesbury, K.P., K.C.V.O., will preside to-night (Wednesday), at a Special Conference on Summer Diarrhœa, to be held at the Queen's Hospital for Children, Bethnal Green, to consider the prevalence each year of summer diarrhœa and to recommend measures for preventing the disease. Special efforts were made by the hospital last year to combat the evil by distributing simply-worded instruction papers to mothers, but it was felt that very little could be done without the co-operation of other charitable agencies and of the local public health authorities. The hospital receives patients from all parts, but the cases of summer diarrhœa treated there come mainly from Bethnal Green, Shoreditch, and Hackney, which together have a population of close upon half a million, and the Conference will be confined, therefore, to representatives of those districts.

MR. H. HAES (Kelvedon).—We are not aware of any observations upon the matter to which you refer. The idea that the whole physical system of man undergoes any sort of annual change does not appear to be supported by any scientific evidence.

Meetings of the Societies, Lectures, &c

WEDNESDAY, MARCH 11TH.

HUNTERIAN SOCIETY (St. Bartholomew's Hospital (Library), E.C.).—9 p.m.: Papers:—Dr. W. H. Kelson: Nasal Suppuration, more Particularly as Associated with Diseases of the Eye. Dr. R. D. Maxwell. Specimens of Two Fœtal Heads—(1) Hydrocephalic, (2) Defective Ossification—with Remarks on their Obstetric Significance. Mr. A. S. B. Bankart: Colles's Fracture and its Treatment.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common, S.W.).—9 p.m.: Dr. C. O. Hawthorne: The Clinical Value of the Instrumental Estimation of Blood Pressure.

THURSDAY, MARCH 12TH.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical College, Crosvenor Road, S.W.).—5 p.m.: Major E. T. F. Birrell, R.A.M.C.: Some Experiences of the Balkan War.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Harveian Lecture:—Mr. D'Arcy Power: English Medicine and Surgery under Edward III. (illustrated by lantern slides).

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Board Room of the Great Northern Central Hospital, Holloway Road, N.).—9 p.m: Paper:—Dr. L. Barlow: Radium and Radiation as a Therapeutic Agent.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (49 Leicester Square, W.C.).—6 p.m.: Dr. M. Dockrell: Treatment by Cataphoresis and Electro-inunction.

FRIDAY, MARCH 13TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Mr. Henry Curtis, and others. Short Paper:—Mr. V. Zachary Cope: Traumatic Sensory Aphasia

TUESDAY, MARCH 17TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THERAPEUTICS AND PHARMACOLOGY) (1 Wimpole Street, W.).—4.30 p.m.: Paper:—Dr. G. C. Low: The Therapeutic Uses of Emetine

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Dr. J. F. Gaskell: The Lesions of the Kidney in Ulcerative Endocarditis.

Appointments.

CANDLER, ARTHUR LAWRENCE, M.B., B.S.Lond., F.R.C.S.Eng., L.R.C.P.Lond., Honorary Anæsthetist to the Devon and Exeter Dental Hospital.

FREW, ROBERT S., M.D.Edin., Assistant Physician for Diseases of Children at King's College Hospital.

JENKINS, E. L., M.B., B.S.Durh., Certifying Surgeon under the Factory and Workshop Acts for the Lynton District of the County of Devon.

O'CONNOR, EDWARD, M.B., B.Ch.Oxon., Clinical Assistant to All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge Road, S.W.

O'REILLY, T. P., L.R.C.P.Irel., Medical Officer for Tuberculosis in County Cavan, Ireland.

RODGER, M. M., M.D., Ch.B.Glasg., Assistant Medical Officer at the Cardiff Mental Hospital.

SAMUELS, ISIDORE, L.D.S.Eng., Dental Surgeon to the Devon and Exeter Hospital.

WARDROP, J. G., M.R.C.S., L.R.C.P.Lond., House Physician at University College Hospital.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointment:—Shoreham (Sussex).

Senior Assistant Medical Officer.—Caterham Asylum, Caterham, Surrey.—Salary, £300 per annum, with board, lodging and washing. Applications to the Clerk to the Metropolitan Asylums Board, Embankment, E.C.

City of Nottingham.—Assistant Medical Officer. Salary £165 per annum, with apartments, etc. Applications to J. Allan Battersby, Clerk to the Board, Poor-law Offices, Shakespeare Street, Nottingham.

Dorset County Hospital, Dorchester.—House Surgeon.—Salary, £125 per annum, with residence, board and laundry. Applications to W. E. Groves, Valetta, Icenway, Dorchester.

Derby County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent, Asylum, Maidstone.

Births.

FENWICK.—On March 2nd, at 19 Forres Gardens, Golder's Green, N.W., the wife of W. Stephen Fenwick, M.S., F.R.C.S., of a son

STRICKLAND.—On February 28th, at The Limes, Southend-road, Beckenham, Kent, to Georgina, wife of Harold F. Strickland, F.R.C.S., of a son.

TURNER.—On March 2nd, at 18 Harley Street, W., the wife of William Aldren Turner, M.D., of a son.

WATSON.—On March 2nd, at Leigh House, Leigh-on-Sea, the wife of W. Douglas Watson, M.R.C.S., L.R.C.P., D.P.H., of a son.

Marriages.

CRAIG—CRESSALL.—On February 14th, at St. Sidwell's, Georgetown, Demerara, George Ernest Craig, M.B., University, Dublin, British Guiana Medical Service, second son of Mr. and Mrs. R. J. Craig, Londonderry, Ireland, to Ethel Harriet Beatrice, eldest daughter of Mr. and Mrs. Paul Cressall, Georgetown, Demerara.

WADDY—HENSLEY.—On March 6th, at St. Mary's Church, Cairo, Richard Granville Waddy, B.Sc.Oxon., M.B., Ch.M., Sydney, of the Public Health Dept., Egypt, son of Col. and Mrs. Waddy, Morpeth, N.S.W., and grandson of the late Sir Richard Waddy, K.C.B., to Dorothy Maude Filleul, second daughter of the late F. F. Hensley, P.W.D., India, and Mrs. C. W. Haig Brown, of Charterhouse, Godalming.

Deaths.

FREYER.—On March 2nd, at Nice, Isabella, wife of Lieut.-Colonel P. J. Freyer, late I.M.S., of 27 Harley Street, London.

STEWART.—On February 27th, at the Prebendal House, Aylesbury. Dr. Donald Stewart, founder of the Nottingham Throat and Ear Hospital, aged 71.

PARKER.—On March 4th, at St. Leonard-on-Sea, Colonel Walter Augustus Parker, late Royal Army Medical Corps, in his 65th year.

Fragment of a Stele of Victory.

The scene represents the burial of the dead after a battle in which a Sumerian King has been victorious over his enemies. Two Sumerians carry baskets of earth upon their heads to complete the work of burial by making the heap of slain into a mound or "tell." The tassel markings at the edge of their characteristic costume have been extended as a border design. Date, circa 2900 B.C.

A CASE OF GONORRHŒAL FOLLICULAR URETHRITIS

Treated by COLLOIDAL IODINE.

By MARCEL DESCHAMPS,
late House Physician, Assistant to Dr. Bazy, of the "Hopital Beaujon"; and
JEAN PERIGAULT,
late House Physician of the Infirmerie Centrale des Prisons.

The spread of the gonococcal infection to the follicles of the urethra produces lesions the refractoriness of which is often the despair both of the patient and of the medical attendant; the relatively rapid cure of a case of suppurating and fistulous folliculitis which we have achieved by means of simple medical treatment seems to justify our publishing the following:—

The patient, aged twenty, presented himself at the special department for the treatment of urinary diseases of the Beaujon Hospital on the 20th November, 1913. This patient had been suffering from gonorrhœa since the 20th of October, and had treated himself without success with potassium permanganate irrigations.

On the lower surface of the penis and in its middle portion there was a hard tumour as thick as a nut. This tumour was only painful during erection. The urethral discharge showed abundant gonococci.

We at once submitted our patient to a course of Nicholle's anti-gonococcal vaccine, of which he received a daily injection according to the rules laid down by the author, the treatment being kept up for eleven days.

This treatment exerted no influence either on the discharge (which in no way diminished in intensity) nor on the folliculitis, which progressed in the ordinary manner towards suppuration and culminated in discharging by several small apertures on the 26th of November a sero-purulent fluid which, when examined microscopically, proved to contain gonococci. During the days that followed no change whatever could be found in the urethral discharge; the folliculitis underwent softening, discharging very slowly its sero-purulent fluid. At the same time, a track of lymphangitis appeared on the right side of the penis, an indurated strand being noticed on palpation; the patient was, in fact, whilst undergoing treatment, passing through an attack of lymphangitis of the main lymphatics.

On the 30th of November the glandular and lymphatic induration had increased; the temperature had reached 38° C. On the 3rd of December the condition had remained stationary, and the patient was treated by means of extensive irrigation with oxy-cyanide. Though continued up to the 22nd of December, these irrigations did not succeed in drying up the discharge, which had become an obstinate gleet. The folliculitis remained the size of a hazel-nut, hard, and always discharging sero-purulent fluid through the fistulæ; it remained in this condition without any change of consistence, and manifested all signs of chronicity.

We then commenced treatment by means of Colloidal Iodine, injecting it into the anterior part of the urethra to the level of the folliculitis. On the 3rd of January, though the folliculitis did not appear to have been influenced, the discharge had considerably diminished. From this time onward the illness distinctly took a turn towards cure, and the folliculitis commenced to ameliorate, whilst the discharge dried up and the fistulæ closed spontaneously.

On the 15th of January the folliculitis had completely disappeared; seventeen days after commencing the Colloidal Iodine treatment no trace of induration remained; palpation of the urethra on a Benique showed that the canal was absolutely supple, and showed no trace of follicular abscess. **Complete absorption had taken place without the least trace of cicatricial tissue.**

We employed a preparation of Colloidal Iodine obtained by electro-chemical means, and rendered stable by a carbohydrate (Iodargol). Our preparation gave a titre of 20 cg. of Colloidal Iodine to the cubic centimetre. The injection of this product never was in the least painful; it has besides been possible to demonstrate in other cases of gonorrhœa treated by the same method that the pain on micturition disappeared in the course of the acute stage, and the latter is also shortened considerably by injections of Colloidal Iodine.

We have administered doses up to from 2-5 cc. without any bad effects either local or general being produced. It is, in fact, known that iodine when brought into the colloidal state increases its action tenfold and diminishes in toxicity to the same amount.

Nevertheless, we have been satisfied in keeping to doses of 2 cc. (i.e., 40 cg., 6 grs., of Colloidal Iodine), since the higher doses do not seem to us to produce any greater therapeutic effects. The injection was retained by the patient for two hours by means of a constricting dressing which prevented the fluid from escaping.

It has seemed to us of some interest to report this case on account of the result obtained, and above all on account of the means employed for attaining it; for follicular abscesses of gonorrhœal origin, however they may start, always sooner or later acquire chronic symptoms, and we have never so far seen any but surgical treatment leading to a certain cure.

The disinfection and incision of the abscesses from the urethral side, massage after Benique's method, have never led to complete absorption of the lesions. Whenever one has tried to treat the folliculitis in its initial stage, before it has passed on to softening, it should be removed in as aseptic a manner as possible without being opened; if it has suppurated the pocket should be freely opened and disinfected; if it has assumed a cystic appearance, after cooling, it should still be removed surgically. Such is the regular course taken by all experienced practitioners.

The success which has attended our urethral dressings with Colloidal Iodine seems to give some promise that the necessity for the radical methods of surgical treatment we have above enumerated in cases of urethral folliculitis of gonorrhœal origin may be somewhat reduced.

Revue de Therapeutique Medico-Chirurgicale,
15th February, 1914.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVIII. WEDNESDAY, MARCH 18, 1914. No. 11.

NOTES AND COMMENTS.

The Family Encyclopædia.

IT will be a matter of some interest to see if the General Medical Council intends to take any notice of the publication of signed articles in a popular medical encyclopædia by leaders of the medical profession, and the wide advertisement of their names in connection therewith. After all, the Council is the only body that has any control over advertisement by medical men, and it has often enough brought down the whole weight of its penal vengeance upon unfortunate practitioners who have endeavoured to found or to fillip a practice by means of handbills or other advertisements. Probably, in the case of the encyclopædia, the Council would have no *locus standi*, as the advertising was done by the proprietors of the book. Some of the men whose names have been thus pilloried in the public Press have written disavowing any connection with the encyclopædia beyond reading a few of the proof sheets at the request of the editor, a medical man. In that case there should be some *prima facie* grounds for a civil action for damages. These gentlemen deserve every sympathy, but some of their companions in misfortune have previously had the courage to publish their names and hospital and other appointments in documents addressed deliberately to the public Press. That, again, appears to be a matter of individual taste, and constitutes an ethical action beyond the control of the General Medical Council.

2,000 Prescriptions.

THE encyclopædia is of the regular "enquire within about everything" order. The harm likely to be done by such a work is enormous, for there could hardly be anything more fraught with danger to himself and his friends than the misguided individual who reads up a medical book and thinks he is qualified to treat maladies of various kinds. Yet the family guide in question boasts that it has 2,000 prescriptions, and these have been put upon the public market under the authority of a long list of the most prominent members of the medical profession, titled and otherwise. The publication of these prescriptions is likely to do an immense amount of harm to the profession generally, for many persons would hesitate to pay two guineas for a prescription that can be got free, gratis and for nothing out of a book. The General Medical Council probably have no more power of control over this than they have over publishers' advertisements. The fact of the matter seems to be that the code of medical ethics is undergoing a complete revolution. The publication of signed letters on medical subjects by well-known medical men has been going on for years past and no one seems to have taken much notice of the practice. Latterly interviews with prominent men on hospital staffs have been in evidence, and signed articles on professional subjects have been plentiful as blackberries in the lay newspaper Press.

Americanising the Profession.
